In general, one group is only configured with one route reflector. In this case, the Device ID of the route reflector can be used to identify this cluster. To increase the redundancy, you can set more than one route reflector within this cluster. In this case, you must configure the cluster ID, so that one route reflector can identify the route update from other route reflectors of this cluster.

**Configuration  
Examples**

The following example configures the cluster ID of the route reflector.

```
Ruijie(config)# router bgp 65000
```

```
Ruijie(config-router)# bgp cluster-id 10.0.0.1
```

## 5.33 bgp confederation identifier

Use this command to configure the AS confederation identifier. Use the **no** form of this command to restore the default setting.

**bgp confederation identifier** *as-number*

**no bgp confederation identifier**

| Parameter<br>Description | Parameter        | Description                                                                                                                                                                                                                                                    |
|--------------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>as-number</i> | AS confederation identifier in the range from 1 to 65535<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, which is represented as 1 to 65535.65535 in dot mode. |

**Defaults** There is no confederation identifier by default

**Command**

**Mode** BGP configuration mode/BGP scope global configuration mode

**Usage  
Guide**

The confederation is a measure to reduce the connections of IBGP peers within the AS. One AS is divided into several sub ASs and one unified confederation ID (namely, confederation AS number) is set to constitute these sub ASs into a confederation. For the external confederation, the whole confederation is still considered as one AS, and only the confederation AS number is visible for the external network. Within the confederation, the full IBGP peer connection is still established among the BGP Speakers within the sub AS, and the EBGP connection is established among the BGP Speakers within the sub AS. Despite of the EBGP connections established between the BGP speakers in an AS, the next-hop, MED and local priority information remains unchanged in exchanging the information.

**Configuration Examples** The following example configures the AS confederation identifier.

```
Ruijie(config-router)# bgp confederation identifier 65000
```

## 5.34 bgp confederation peers

Use this command to configure member ASs of the AS confederation. Use the **no** form of this command to restore the default setting.

**bgp confederation peers** *as-number* [...*as-number*]

**no bgp confederation peers** *as-number* [...*as-number*]

| Parameter<br>Description | Parameter        | Description                                                                                                                                                                                                                                         |
|--------------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>as-number</i> | Member ASs in the confederation range from 1 to 65535.<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |

## Defaults

There is no confederation member by default.

## Command

## Mode

BGP configuration mode/BGP scope global configuration mode

### Usage Guide

The confederation is a measure to reduce the connections of BGP peers within the AS. One AS is divided into several sub ASs and one unified confederation ID (namely, confederation AS number) is set to constitute these sub ASs into a confederation. The whole external confederation is still considered as one AS, and only the confederation AS number is visible for the external network. Within the confederation, the full IBGP peer connection is still established among the BGP Speakers within the sub AS, and the EBGP connection is established among the BGP Speakers within the sub AS. Despite of the EBGP connections established between the BGP speakers in an AS, the next-hop, MED and local priority information remains unchanged in exchanging the information.

This command is used to specify the member AS of a confederation.

-  This command can configure up to 25 members of a confederation at one time. For more members, enter them for several times.
-  Run the [ **default** | **no** ] **bgp confederation peers** command without AS number will delete all AS member configuration.

## Configuration

The following example configures member ASs of the AS confederation.

## Examples

```
Ruijie(config-router)# bgp confederation peers 65000 65100
```

## 5.35 bgp dampening

Use this command to enable the routing attenuation and set the attenuation parameters in the address-family or routing configuration mode. Use the **no** form of this command to restore the default setting.

**bgp dampening** [ *half-life* [ *reusing* *suppressing* *max-supress-time* ] ] **route-map** *name* ]  
[ **withdrawal-ignore** ]

**Parameter  
Description**

| Parameter                | Description                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>half-life</i>         | Half-life period, ranging from 1 to 45 minutes                                                                     |
| <i>reusing</i>           | When the penalty value reaches this value, the routing suppression is cancelled. The value ranges from 1 to 10000. |
| <i>suppressing</i>       | When the penalty value reaches this value, routing is suspended. The value ranges from 1 to 20000.                 |
| <i>max-supress-time</i>  | Maximum time for routing suppression, ranging from 1 to 255 minutes                                                |
| <b>withdrawal-ignore</b> | The penalty value is not added when the routing suppression is cancelled.                                          |
| <i>name</i>              | Route-map name, apply the routing attenuation to the specified route through the route-map.                        |

**Defaults**

This function is disabled by default.

**Command  
Mode**

BGP configuration mode, BGP IPv4 unicast address-family configuration mode, BGP IPv4 VRF address-family configuration mode, BGP IPv6 unicast address-family configuration mode, BGP IPv6 VRF address-family configuration mode, BGP L2VPN VPLS/VPWS/EVPN address-family configuration mode, or BGP scope configuration mode.

**Usage  
Guide**

The **bgp dampening** command is used to suppress unstable BGP routing. The BGP uses the penalty value to describe routing suppression intensity. The penalty value increases 1000 when the routing oscillation is performed once. The suppressed routes will not be used during the BGP routing election.

The **bgp dampening** command is used to suppress unstable EBGP routes and does not take effect to IBGP routes.

The BGP uses the penalty value to describe the route stability. A larger penalty value indicates a more unstable route. The penalty value increases by 1000 when route oscillation occurs (upon receiving withdraw packets). The penalty value does not increase when the upper limit is reached. The upper limit is determined based on the configured max-supress-time value and calculated

using the following formula:  $\text{Penalty upper limit} = 2^{\text{(max-suppress-time/Half-life)}} \times \text{Reusing}$ . In addition, the penalty upper limit cannot be greater than 20000. Therefore, the max-suppress-time, half-life, and reusing values need to be adjusted based on the network conditions. The relationship among these parameters are as follows:

$\text{Half-life} \leq \text{max-suppress-time}$

$\text{Reusing} \leq \text{Suppressing} \leq \text{Penalty upper limit}$

You can also specify only the half-life value. In this case, the max-suppress-time value is (half-life x 4), the reusing value is 750, and the suppressing value is 2000.

EBGP routes whose penalty value exceeds the suppressing value will be suppressed. Suppressed routes will not be used during BGP route election and will not be advertised to other BGP peers. If route oscillation occurs in suppressed routes, the penalty value will continue to increase until the penalty upper limit is reached.

The penalty value of suppressed routes will decrease by a half each time the half-life time passes. When the penalty value decreases to the reusing value, routes whose attribute is update in the last update will participate in BGP route election again. When the penalty value decreases to 0, routes whose attribute is withdraw in the last update will be deleted from the BGP route table.

By default, 1000 penalty values are added for route cancellation and 500 penalty values are added for route update.

Use the **withdrawal-ignore** command to not add penalty values for route cancellation.

**Configuration** The following example enables the routing attenuation and set the attenuation parameters.

**Examples** Ruijie(config-router)# bgp dampening 30 1500 10000 120

## 5.36 bgp default ipv4-unicast

Use this command to set the IPv4 unicast address as the default address family. Use the **no** form of this command to restore the default setting.

**bgp default ipv4-unicast**

**no bgp default ipv4-unicast**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** The IPv4 unicast address is the default address family.

**Command** BGP configuration mode/BGP scope global configuration mode

**Mode****Usage****Guide**

This command is used to set the default address family of BGP as the IPv4 unicast address.

**Configuration**

The following example sets the IPv4 unicast address as the default address family.

**Examples**

```
Ruijie(config-router)# default ipv4-unicast
```

**Related****Commands**

| Command                    | Description                   |
|----------------------------|-------------------------------|
| <b>address-family ipv4</b> | Enters the IPv4 address mode. |

**Platform****Description**

## 5.37 bgp default local-preference

Use this command to set the default local-preference attribute value. Use the **no** form of this command to restore the default setting.

**bgp default local-preference** *value*

**no bgp default local-preference**

**Parameter****Description**

| Parameter    | Description                                                 |
|--------------|-------------------------------------------------------------|
| <i>value</i> | Local priority attribute, in the range from 0 to 4294967295 |

**Defaults**

The local preference value is 100 by default.

**Command****Mode**

BGP configuration mode/BGP scope configuration mode

**Usage**

The BGP takes the local preference as the foundation to compare with the priority of the path learned from IBGP peers. The larger the local preference value, the higher the priority of the path is.

**Guide**

The BGP speaker sends the external route received to the IBGP peers to add the local priority value.

**Configuration**

The following example sets the default local-preference attribute value.

**Examples**

```
Ruijie(config-router)# bgp default local-preference 200
```

**Related****Commands**

|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>show ip bgp</b>             | Displays the BGP route entry.                                                                               |
| <b>bgp always-compare-med</b>  | Allows comparing the MED value of the path of the peer from different ASs when electing the optimal path.   |
| <b>bgp bestpath med confed</b> | Allows comparing the MED value of paths of internal peers from AS community when electing the optimal path. |

|                                          |                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>bgp bestpath med missing-as-worst</b> | Allows setting the priority of the path without MED attribute as the lowest when electing the optimal path. |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------|

**Platform****Description** None

## 5.38 bgp default route-target filter

Use this command to enable the route-target filtering. For the VPNv4 routes, filter the community attributes of the route-target by default. Use the **no** form of this command to disable this function.

**bgp default route-target filter****no bgp default route-target filter**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command** BGP configuration mode, VPNv4 address-family configuration mode, or BGP L2VPN  
**Mode** VPLS/VPWS/EVPN address-family configuration mode or BGP scope configuration mode.

**Usage** After receiving the VPNv4 route, use the community attributes list of the route-target to filter and distribute different VRFs. With the no form of this command used, the BGP will receive all VPNv4 routes no matter whether these filtered VPNv4 routes will be received by route-target of local VRF.

**Guide** With the PE route-reflector-client configured for the BGP, the VPNv4 route will not be processed through the route-target filtering. In this case, whether the BGP is enabled, the actions are the same without the route-target filtering.

**Configuration** The following example enables the route-target filtering.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# no bgp default route-target filter
```

## 5.41 bgp fast-external-fallover

When the network interface used in establishing the connection of the directly-connected EBGP peer fails, use this command to establish the BGP session connection quickly. Use the **no** form of this command to disable this function.

**bgp fast-external-fallover**

**no bgp fast-external-fallover**

## 5.42 bgp fast-reroute

Use this command to enable BGP Fast Reroute. Use the **no** or **default** form of this command to restore the default settings.

**bgp fast-reroute**

**no bgp fast-reroute**

**default bgp fast-reroute**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode/ BGP IPv4 unicast address family configuration mode/ BGP IPv6 unicast address family configuration mode/ BGP IPv4 VRF address family configuration mode/ BGP IPv6 VRF address family configuration mode/ BGP scope global configuration mode

**Usage Guide**

-  Only one backup route will be generated and the next-hop of this backup route cannot be the same as that of the preferred route.
-  When ECMP is enabled, the FRR cannot generate backup route.
-  When this function is enabled, the priority of BGP FRR is lower than that of VPN FRR. So when the VPN FRR is enabled in IPv4 VRF configuration mode, BGP FRR does not take effect unless VPN FRR is unable to calculate the backup route.
-  This command can not be run with **bgp install standby-path**.

**Configuration Examples**

The following example enables BGP Fast Reroute.

```
Ruijie(config)# router bgp 65530
Ruijie(config-router)# bgp faster-reroute
```

## 5.43 bgp fast-withdraw

Use this command to configure fast withdrawal of specified BGP route. Use the **no** or **default** form of this command to restore the default settings.

**bgp fast-withdraw** { **access-list** { *access-list-number* | *access-list-name* } | **prefix-list** *prefix-list-name* | **route-map** *map-tag* }

**no bgp fast-withdraw** { **access-list** | **prefix-list** | **route-map** }

**default bgp bgp fast-withdraw** { **access-list** | **prefix-list** | **route-map** }

| Parameter                 | Description                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------|
| <i>access-list-number</i> | Indicates the ACL number. The value ranges from <b>1</b> to <b>199</b> and <b>1300</b> to <b>2699</b> . |
| <i>access-list-name</i>   | Indicates an ACL name.                                                                                  |
| <i>prefix-list-name</i>   | Indicates the name of a prefix list.                                                                    |
| <i>map-tag</i>            | Indicates the name of a route map.                                                                      |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode/ BGP IPv4 or IPv6 unicast address family configuration mode/ BGP IPv4 or IPv6 VRF address family configuration mode/ BGP VPNv4 address family configuration mode/ BGP L2VPN VPWS/VPLS/EVPN address family configuration mode/ BGP scope global configuration mode.

**Usage**  The BGP L2VPN address family configuration mode only supports **route-map** command.

**Guide**  Command **prefix-list** and **access-list** cannot take effect at the same time.

**Configuration Examples** The following example enables fast withdrawal of specified BGP route.

```
Ruijie(config)# router bgp 65530
Ruijie(config-router)# bgp fast-withdraw route-map bgp-filter
```

## 5.44 bgp graceful-restart

Use this command to enable the global BGP graceful restart function. Use the **no** form of this command to disable BGP graceful restart.

**bgp graceful-restart****no bgp graceful-restart**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** By default, BGP graceful restart is enabled so as to help neighbors to perform graceful restart.

**Command**

**Mode** BGP configuration mode/BGP scope global configuration mode

The ability of the BGP is advertised and negotiated through the ability field of the Open message. The ability is negotiated during initially setting up the connection. So both sides must reach the consistency of the ability. If it is not supported by any side, this router device will perform the GR incorrectly.

With the GR function enabled, the connected Open message will carry the GR ability field to perform the negotiation of the GR ability. To implement the GR correctly, the GR function must be enabled on both sides of the neighbors.

**Usage Guide**

 This command does not take effect immediately on all BGP connections that are set up successfully. To negotiate the GR ability immediately, you need to restart the BGP connection to make the local device negotiate the GR ability with the Peer again by using the clear ip bgp command.

The BGP graceful-restart is used to forward data continuously of the whole network, it requires the device to keep the BGP routing entry valid and forward data continuously when restarting the BGP protocol. Supporting the continuous forwarding during the restarting is related to the hardware ability.

**Configuration Examples**

The following example enables the graceful restart function of the global BGP.

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp graceful-restart
```

**Related Commands**

## 5.45 bgp graceful-restart disable

Use this command to disable GR capability of a BGP address family. Use the **no** form of this command to restore the default setting.

**bgp graceful-restart disable**  
**no bgp graceful-restart disable**

**Parameter**  
**Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The function is disabled by default.

**Command Mode** BGP configuration mode, IPv4 unicast address family mode, VPNv4 address family mode, L2VPN VPWS/VPLS/EVPN address family mode and scope configuration mode

**Usage Guide** When BGP GR function is enabled, the GR capability for all address families is enabled by default, except for address families that do not support GR capability. After GR capability is enabled, you can use this command in the address family mode to disable the address family's GR capability. The Configuration of this command in BGP mode is effective on IPv4 Unicast address family. When BGP GP function is disabled, GR capability is disabled for all address families.

**Configuration Examples** The following example enables the graceful restart function of the global BGP.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp graceful-restart
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# bgp graceful-restart disable
```

**Configuration Examples**

| Command                     | Description                          |
|-----------------------------|--------------------------------------|
| <b>bgp graceful-restart</b> | Enables BGP's GR capability.         |
| <b>address-family ipv4</b>  | Enters BGP IPv4 address family mode. |

**Description**

## 5.46 bgp graceful-restart restart-time

Use this command to configure the restart time of the BGP graceful-restart. Use the **no** form of this command to restore the default setting.

**bgp graceful-restart restart-time** *restart-time*  
**no bgp graceful-restart restart-time**

**Parameter**  
**Description**

| Parameter           | Description                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>restart-time</i> | GR Restarter-hoped longest waiting time before re-establishing the connection between the GR Helper and the GR Restarter, in the range from 1 to 3600 in the unit of seconds. |

**Defaults** The default is 120.

**Command**

**Mode** BGP configuration mode/BGP scope global configuration mode

The restart time is advertised by GR Restarter to GR Helper, it is GR Restarter-hoped longest waiting time before re-establishing the connection between GR Helper and GR Restarter. After this time, if the BGP connection with GR Restarter is not in Established status, GR Helper will consider this BGP session failed and will restore the normal BGP. All the routing of the neighbor will be deleted during this period, affecting the data redistribution.

The restart time is advertised in the GR ability field of the BGP Open message. The GR restart time of the two ends of the session is not required to be the same, but it is recommended.

#### Usage Guide

 This command does not take effect immediately on all BGP connections that are set up successfully. To advertise the newly set restart time to the GR helper, you need to restart the BGP connection to negotiate the GR ability again and advertise the restart time by using the clear ip bgp command. The configured restart time should not be greater than the Hold Time of the BGP peer, if so, the Hold time will be the restart time when the GR ability is advertised to the BGP peer.

#### Configuration Examples

The following example configures the restart time of the BGP graceful-restart.

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp graceful-restart
Ruijie(config-router)# bgp graceful-restart restart-time 150
Ruijie(config-router)# no bgp graceful-restart restart-time
```

#### Related Commands

**Description**

## 5.47 bgp graceful-restart stalepath-time

Use this command to configure the time to help the device keep the route valid when executing the BGP graceful-restart. Use the **no** form of this command to restore the default setting.

**bgp graceful-restart stalepath-time stalepath-time** *time*

**no bgp graceful-restart stalepath-time**

#### Parameter Description

| Parameter   | Description                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>time</i> | Longest time used to keep the stale route valid after restoring the connection with the neighbors, in the range from 1 to 3600 in the unit of seconds |

**Defaults** The default is 360.

**Command**

**Mode** BGP configuration mode

**Usage  
Guide**

This command is configured for the parameters of the GR Helper. The stalepath-time is the longest time of the GR Helper waiting to receive the EOR mark of the Restarter after restoring the connection with the GR Restarter. When the GR Helper detects that the connection with the GR Restarter fails, the original route of the Restarter is marked as the "Stale". However these routes are still used for the routing calculation and forwarding.

The GR Helper updates the routes and cancels the "Stale" mark according to route updating information received from the GR Restarter. If routes marked as "Stale" are not updated in the stalepath-time period, they will be deleted. This mechanism is used to avoid failure in convergence of routes when the GR Helper fails to receive the EOR mark of the GR Restarter for a long time.

**Configuration  
Examples**

The following example configures the restart time of the BGP graceful-restart.

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp graceful-restart
Ruijie(config-router)# bgp graceful-restart stalepath-time 240
Ruijie(config-router)# no bgp graceful-restart stalepath-time
```

**Description**

## 5.48 bgp initial-advertise-delay

Use this command to configure the delay period before a BGP device sends its initial updates to peers. Use the **no** form or **default** form of this command to restore the default settings.

**bgp initial-advertise-delay** *delay-time* [*startup-time*] [**wait-for-controller**]

**no bgp initial-advertise-delay**

**default bgp initial-advertise-delay**

Use this command to enable the BGP delayed advertisement upon system restart. Thus, the route will be immediately sent after the prefix-list policy is matched. Use the **no** form or **default** form of this command to restore the default settings.

**bgp initial-advertise-delay prefix-list** *prefix-list-name*

**no bgp initial-advertise-delay prefix-list**

**default bgp initial-advertise-delay prefix-list**

**Parameter**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                    |                            |                                                                                                                                                                                                |
|--------------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <i>delay-time</i>          | The delay period, in seconds, before a BGP device sends its updates. The range is from 1 to 600. The default value is 1 second.                                                                |
|                    | <i>startup-time</i>        | The time for the BGP device restart. In the period, the neighbor does not send its updates to peers. The range is from 5 to 584,000. The unit is second and the default value is 600 seconds.  |
|                    | <i>prefix-list-name</i>    | Name of the prefix-list. It cannot exceed 32 characters.                                                                                                                                       |
|                    | <b>wait-for-controller</b> | Configures the <b>wait-for-controller</b> command to ensure that routes are advertised only after the controller delivers configuration messages and receives EOR messages from the neighbors. |

**Defaults** The initial advertisement delay is disabled by default.

### Command

**Mode** BGP configuration mode

This command is used to configure parameters for delayed neighbor route advertisement during device restart.

**delay-time** indicates the longest time for sending a route to a neighbor after the BGP neighbor relationship is established. In normal cases, after the neighbor relationship is established, the first route is advertised immediately and subsequent routes are advertised based on the default time.

For details, see the [neighbor advertisement-interval](#) command. **startup-time** indicates the configurable startup time and starts to count when the configuration command takes effect. Within the time specified by **startup-time**, routes to BGP neighbors are advertised periodically based on **delay-time**. This command can be used to change the route advertisement behavior from the BGP peer to neighbors after device restart. The **wait-for-controller** command is used to wait for route advertisement messages from the controller and trigger the BGP route advertisement behavior after EOR messages are received from neighbors. If EOR messages are not received from neighbors within the time specified by **startup-time**, routes are sent forcibly.

The prefix-list policy is configured to ensure that partial routes can be normally delivered. The prefix-list policy applies to distributed routes. Matched routes will be normally delivered without being affected by delayed advertisement. For details about the address family scope to which the prefix-list policy applies, see the **neighbor prefix-list** command.

This command is used by the administrator to adjust the BGP route advertisement behavior during device restart based on the hardware conditions, number of neighbors, number of routes, and actual deployment requirements.

### Usage

#### Guide

The following example configures initial delay to 60 seconds within 500 seconds after BGP restart.

### Configuration

#### Examples

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp initial-advertise-delay 60 500
```

**Description**

## 5.49 bgp install standby-path

Use this command to enable BGP multi-path bypass protection. Use the **no** form or **default** form of this command to restore the default settings.

**bgp install standby-path**

**no bgp install standby-path**

**default bgp install standby-path**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** The BGP multi-path bypass protection is disabled by default.

**Command Mode** BGP configuration mode; BGP IPv4 VRF address family configuration mode; BGP IPv6 VRF address family configuration mode

**Usage Guide**  The BGP multi-path bypass protection function and the FRR function cannot be enabled at the same time.

**Configuration Examples** The following example enables BGP multi-path bypass protection.

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp install standby-path
```

**Platform** N/A  
**Description**

## 5.50 bgp log-neighbor-changes

Use this command to log the BGP status changes without turning on debug. Use the **no** form of this command to disable this function.

**bgp log-neighbor-changes**

**no bgp log-neighbor-changes**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command**

**Mode** BGP configuration mode/BGP scope global configuration mode

**Usage** The debug command can also be used to log BGP status changes. But this command may consume many resources.

**Configuration** The following example logs the BGP status changes without turning on debug.

**Examples** Ruijie(config-router) # `bgp log-neighbor-changes`

**Related****Commands**

## 5.51 bgp mac-mobility

Use this command to configure the MAC mobility detection. Use the **no** form of this command to disable this function. Use the **default** form of this command to restore the default settings.

**bgp mac-mobility** *timer count* [*delay-timer*]

**no bgp mac-mobility**

**default bgp mac-mobility**

**Parameter****Description**

| Parameter          | Description                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>timer</i>       | Indicates the time using to detect the MAC mobility. During the time, if the MAC mobility is detected for <i>count</i> times, then the MAC conflict occurs and syslog will be printed to inform users. By default, the time is 180s and ranges from 1s to 3600s. |
| <i>count</i>       | Indicates the detection times. By default, it is 5 times and ranges from 1 to 360.                                                                                                                                                                               |
| <i>delay-timer</i> | Delay time of the restoration of MAC conflict. By default, it is 180s and ranges from 1 to 3600.                                                                                                                                                                 |

This function is enabled by default.

**Defaults**

*timer*: 180s

*count*: 5

*delay-timer*: 180s

**Command**

**Mode** BGP L2VPN EVPN address family mode

**Usage** MAC address mobility may occur many times. When MAC mobility is detected by a PE, a timer will

**Guide** be enabled (default *timer*: 180s). If the MAC mobility is detected for *count* times (default *count*: 5) before the time passes, then the MAC address is duplicated.

After the MAC conflict occurs, the corresponding EVPN route will not be advertised to neighbors and a timer to delay the restoration will start (default timer: 180s). When the time runs out, the MAC conflict is deleted and the EVPN route is advertised again.

The following example configures MAC mobility detection.

**Configuration**

```
Ruijie(config)# router bgp 65000
```

**Examples**

```
Ruijie(config-router)# address-family l2vpn evpn
```

```
Ruijie(config-router-af)# bgp mac-mobility 120 6
```

## 5.52 bgp maxas-limit

Use this command to set the maximum number of ASs in the BGP AS-PATH attribute. Use the **no** or **default** form of the command to restore the default configuration.

**bgp maxas-limit** *number*

**no bgp maxas-limit**

**default bgp maxas-limit**

**Parameter****Description**

| Parameter     | Description                                                                         |
|---------------|-------------------------------------------------------------------------------------|
| <i>number</i> | The maximum number of ASs in the BGP AS-PATH attribute. The range is from 1 to 512. |

**Defaults**

No maximum number of ASs is set by default.

**Command****Mode**

BGP configuration mode/BGP scope global configuration mode

**Usage**

The routes exceeding the AS number limit are discarded directly, After changing the configuration,

**Guide**

use the **clear** command to reset the neighbor and make the configuration take effect.

**Configuration**

The following example sets the maximum number of ASs in the BGP AS-PATH attribute to 100.

**Examples**

```
Ruijie(config-router)# bgp maxas-limit 100
```

## 5.53 bgp maximum-neighbor

Use this command to configure the maximum number of BGP neighbors when sending warnings. Use the **no** or **default** form of the command to restore the default configuration.

**bgp maximum-neighbor** *numbers* **warning-only**

**no bgp maximum-neighbor**

**default bgp maximum-neighbor**

| Parameter          | Parameter      | Description                                              |
|--------------------|----------------|----------------------------------------------------------|
| <b>Description</b> | <i>numbers</i> | Indicates maximum number of neighbor. Range: 1 to 15000. |

**Defaults** The function is disabled by default.

**Command**

**Mode** BGP configuration mode, BGP scope global configuration mode.

**Usage**

**Guide** N/A

**Configuration**

The following example sets the maximum number of neighbor as 1000.

**Examples**

```
Ruijie(config)#router bgp 100
Ruijie(config-router)#bgp maximum-neighbor 1000 warning-only
```

| <b>Defaults</b>               | The function is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                        |
| <b>Command</b>                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                        |
| <b>Mode</b>                   | BGP configuration mode/ BGP scope global configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                        |
| <b>Usage</b>                  | When a route advertisement in an address family causes the current number of BGP routes to exceed the maximum number, a prompt indicating route overflow in the global or specified VRF is displayed, and the BGP global or specified VRF is set to the overflow state.                                                                                                                                                                                                                                                                                                                                                             |                                                        |
|                               | Run the <b>show bgp { addressfamily   all } summary</b> command to check routing information base status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                        |
| <b>Guide</b>                  | If the address family enters the overflow state because the BGP routing information prefix reaches the upper limit, it can be adjusted by <b>maximum-prefix</b> .<br>For IPv4 unicast routes, the routing information prefix may still be received if it is in the overflow state in the following cases:<br>1) The routing information of the same routing prefix already exists in the routing information base;<br>2) A route that covers the prefix (except the default route) already exists in the routing information base, and the next hop of the route is different from the next hop of the newly received route prefix. |                                                        |
| <b>Configuration Examples</b> | <p>The following example sets the maximum number of routes to 100.</p> <pre>Ruijie(config)#router bgp 100 Ruijie(config-router)#bgp maximum-prefix 100</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                        |

## 5.55 bgp mp-error-handle session-retain

Use this command to retain BGP sessions when BGP protocol detects errors in multi-protocol route attributes. Use the **no** form of this command to restore the default setting.

**bgp mp-error-handle session-retain [ recovery-time time ]**

**no bgp mp-error-handle session-retain**

|                              |                           |                                                                                                                                                   |
|------------------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b>          | <b>Description</b>                                                                                                                                |
|                              | <b>recovery-time time</b> | Configures the waiting time for auto route recovery.<br>The parameter ranges from 10 to 4294967296 in the unit of seconds.<br>The default is 120. |

**Defaults** By default, BGP sessions will be interrupted when multi-protocol attribute errors are detected.

**Command Mode** BGP configuration mode/BGP scope global configuration mode

**Usage Guide** By default, when UPDATA packets are received from a neighbor, BGP sessions will be interrupted if multi-protocol attribute errors are detected, which will cause oscillation of routes of all the address families of the neighbor. An address family's route error will affect the stability of routes of other address families. After this command is configured, when an error of the route attribute of an address family occurs, all the route information of the address family and neighbor will be deleted, thus preventing impact on the BGP session and other protocol address families, improving BGP protocol's stability.

The option `recovery-time` is used to configure the waiting time for auto route recovery. To use the option, the neighbor must support the route refreshing capability. After `recovery-time` expires, BGP will send a route-refresh message to the neighbor's address family and re-notify the neighbor of the address family's all route information.

**Configuration Examples** The following example retains BGP sessions when BGP protocol detects errors in multi-protocol route attributes.

```
Ruijie(config-router)# bgp mp-error-handle session-retain
```

**Configuration Examples**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Description**

## 5.56 bgp nexthop trigger delay

Use this command to configure the delay time for updating the routing table when the nexthop of the BGP route changes. Use the **no** form of this command to restore the default setting.

**bgp nexthop trigger delay** *delay-time*

**no bgp nexthop trigger delay**

**Parameter Description**

| Parameter         | Description                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>delay-time</i> | Delay time for updating the routing table when the nexthop changes, in the range from 0 to 100 in the unit of seconds |

**Defaults** The default is 5.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family

configuration mode/BGP L2VPN VPWS/VPLS/EVPN address family configuration mode or BGP Scope configuration mode.

**Usage** This command is used to configure the delay time for updating the routing table when the nexthop changes, it takes effect when the bgp nexthop trigger enable switch is opened.

**Configuration Examples** The following example retains BGP sessions when BGP protocol detects errors in multi-protocol route attributes.

```
Ruijie(config-router)# bgp nexthop trigger delay 30
```

| Related Commands | Command                           | Description                  |
|------------------|-----------------------------------|------------------------------|
|                  | <b>bgp nexthop trigger enable</b> | Enables the nexthop trigger. |

**Platform**

**Description** None

## 5.57 bgp nexthop trigger enable

Use this command to enable the nexthop trigger update function. Use the **no** form of this command to disable this function.

**bgp nexthop trigger enable**

**no bgp nexthop trigger enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode/BGP L2VPN VPWS/VPLS/EVPN address family configuration mode or BGP Scope configuration mode.

**Usage**

**Guide** This command is used to enable the nexthop trigger update function.

**Configuration Examples** The following example enables the nexthop trigger update function.

```
Ruijie(config-router)# bgp nexthop trigger enable
```

| Related Commands | Command                          | Description                                                                  |
|------------------|----------------------------------|------------------------------------------------------------------------------|
|                  | <b>Bgp nexthop trigger delay</b> | Sets the delay time for updating the routing table when the nexthop changes. |

**Platform****Description** None

## 5.58 bgp notify unsupport-capability

Use this command to enable the neighbor address family capability detection function. Use the **no** form of this command to restore the default setting.

**bgp notify unsupport-capability****no bgp notify unsupport-capability****Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.**Command  
Mode** BGP configuration mode/BGP scope global configuration mode.

**Usage Guide** When BGP neighbor address family capability negotiation is not fully consistent, neighbors can still be connected. After this command is configured, when an address family capability supported by the local device is not supported by the neighbor device, Notification packet that carries the address family that does not support the capability will be send.

**Configuration** The following example enables the neighbor address family capability detection function.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp notify unsupport-capability
```

**Configuration  
Examples**

| Command           | Description           |
|-------------------|-----------------------|
| <b>router bgp</b> | Enables BGP protocol. |

**Platform** N/A**Description**

## 5.59 bgp nsr

Use this command to enable the NSR function for BGP neighbors globally. Use the **no** form or **default** form of this command to restore the default settings.

**bgp nsr****no bgp nsr****default bgp nsr**

## 5.60 bgp recursion host

Use this command to configure BGP routes to be recursive only to host routes. Use the **no** form or **default** form of this command to restore the default settings.

**bgp recursion host**

**no bgp recursion host**

**default bgp recursion host**

| Parameter<br>Description      | Parameter                                                                                                                                                                                                                                                                           | Description |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
|                               | N/A                                                                                                                                                                                                                                                                                 | N/A         |
| <b>Defaults</b>               | By default, recursion is performed on BGP routes via exact matching.                                                                                                                                                                                                                |             |
| <b>Command Mode</b>           | BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode/BGP L2VPN VPWS/VPLS/EVPN address family configuration mode or BGP Scope configuration mode. |             |
| <b>Usage Guide</b>            | This function takes effect on indirect routes only.                                                                                                                                                                                                                                 |             |
| <b>Configuration Examples</b> | The following example enables BGP routes to be recursive only to host routes.<br><pre>Ruijie(config-router)# bgp recursion host</pre>                                                                                                                                               |             |

**Platform** N/A

**Description**

## 5.61 bgp redistribute-internal

Use this command to control BGP whether to allow redistributing routes learned from IBGP, such as RIP, OSPF and ISIS, to the IGP protocol. Use the **no** form of this command to disable this function.

**bgp redistribute-internal**

**no bgp redistribute-internal**

**default bgp redistribute-internal**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** IBGP routes are allowed by default to be redistributed to the IGP protocol.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode or IPv4/IPv6 VRF address family configuration mode

**Usage Guide** This command is used to control whether IBGP routes are allowed to be redistributed to the IGP protocol.

**Configuration Examples** The following example enables the BGP to learn the redistributing routes from IBGP.

```
Ruijie(config-router)# bgp redistribute-internal
```

## 5.63 bgp refresh max-eor-time

Use this command to configure the timer for sending EoRR message to neighbors. Use the **no** form or **default** form of this command to restore the default settings.

**bgp refresh max-eor-time** *time*

**no bgp refresh max-eor-time**

**default bgp refresh max-eor-time**

| Parameter Description | Parameter   | Description                                                                                       |
|-----------------------|-------------|---------------------------------------------------------------------------------------------------|
|                       | <i>time</i> | Timer for sending EoRR message. Range: 0, 600-3600, unit:s. 0 indicates the function is disabled. |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>     | By default, it is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Command Mode</b> | BGP configuration mode and BGP Scope configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Usage Guide</b>  | If the BoRR message is sent to the neighbor but the subsequent EoRR message is not sent, the old routes of the neighbor can not be deleted. For this case, a timer for sending EoRR message is configured. After the BoRR message is sent, the timer is started (based on the neighbor + address family), and the time is set by the user. If the EoRR message is not sent after the set time, the EoRR message of the corresponding address family is sent to the neighbor. The timer is turned off if an |

EoRR message has been sent.

**Configuration** The following example sets the timer for sending EoRR message as 600 seconds.

**Examples**

```
Ruijie(config-router)# bgp refresh max-eor-time 600
```

**Platform** N/A

**Description**

## 5.64 bgp refresh stalepath-time

Use this command to configure the time of Enhanced Route-Refresh old route deletion timer. Use the **no** form or **default** form of this command to restore the default settings.

**bgp refresh stalepath-time** *time*

**no bgp refresh stalepath-time**

**default bgp refresh stalepath-time**

**Parameter  
Description**

| Parameter   | Description                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| <i>time</i> | Time of Enhanced Route-Refresh old route deletion timer. Range: 0, 600-3600, unit:s.<br>0 indicates the function is disabled. |

**Defaults** By default, it is disabled.

**Command  
Mode** BGP configuration mode and BGP Scope configuration mode

**Usage Guide** If only receive the BoRR message but not the EoRR message, then the Enhanced Route-Refresh old routes will remain. For this case, a timer for deleting the old routes is configured. After the BoRR message is received, the timer is started (based on the neighbor + address family), and the time is set by the user. If the EoRR message is not received after the set time, the Enhanced Route-Refresh old routes are deleted. This timer is turned off if an EoRR message is received.

**Configuration** The following example sets the timer as 600 seconds.

**Examples**

```
Ruijie(config-router)# bgp refresh stalepath-time 600
```

**Platform** N/A

**Description**

## 5.65 bgp route-reflector attribute-change

Use this command to allow the BGP route reflector to modify route attributes. Use the **no** form or **default** form of this command to restore the default settings.

**bgp route-reflector attribute-change**

**no bgp route-reflector attribute-change**

**default bgp route-reflector attribute-change**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** By default, the function is disabled.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP L2VPN VPWS/VPLS/EVPN address family configuration mode or BGP Scope configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example allows the BGP route reflector to modify route attributes.

```
Ruijie(config-router)# bgp route-reflector attribute-change
```

**Platform Description** N/A

## 5.66 bgp router-id

Use this command to configure the ID-IP address of the device. Use the **no** form of this command to restore the default setting.

**bgp router-id ip-address**

**no bgp router-id**

| Parameter<br>Description | Parameter         | Description  |
|--------------------------|-------------------|--------------|
|                          | <i>ip address</i> | IPv4 address |

**Defaults** The loop-back interface of the device is selected preferentially by default. If it does not exist, the device route-id of the device is used.

**Command** BGP configuration mode, BGP scope global configuration mode or BGP IPv4/IPv6 VRF address

|              |                                                                                         |
|--------------|-----------------------------------------------------------------------------------------|
| <b>Mode</b>  | family configuration mode                                                               |
| <b>Usage</b> | This command is used to configure IP address, the ID of the device when running the BGP |
| <b>Guide</b> | protocol.                                                                               |

**Configuration** The following example configures the ID-IP address of the device.

**Examples** Ruijie(config-router)# bgp router-id 10.0.0.1

| <b>Related<br/>Commands</b> | Command                                     | Description                                                         |
|-----------------------------|---------------------------------------------|---------------------------------------------------------------------|
|                             | <b>show ip bgp dampening dampened-paths</b> | Displays the suppressed routing information.                        |
|                             | <b>bgp dampening</b>                        | Enables the route dampening function and sets dampening parameters. |

**Platform**

**Description** None

## 5.67 bgp scan-rib disable

Use this command to update the routing table by event triggering. Use the **no** form of this command to restore the default setting.

**bgp scan-rib disable**

**no bgp scan-rib disable**

| <b>Parameter</b>   | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** Timely scan and update is enabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage**

**Guide** N/A

**Configuration** The following example configures the timely scan for the BGP protocol.

**Examples** Ruijie(config-router)# bgp scan-rib disable

| <b>Related<br/>Commands</b> | Command              | Description                                      |
|-----------------------------|----------------------|--------------------------------------------------|
|                             | <b>bgp scan-time</b> | Configures the interval for the BGP timely scan. |

**Platform****Description** None

## 5.68 bgp scan-time

Use this command to configure the interval for the BGP timely scan. Use the **no** form of this command to restore the default setting.

**bgp scan-time** *time*

**no bgp scan-time**

**Parameter****Description**

| Parameter   | Description                                                                   |
|-------------|-------------------------------------------------------------------------------|
| <i>time</i> | Interval of the timely scan, in the range from 5 to 60 in the unit of seconds |

**Defaults**

The default is 60.

**Command Mode**

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode or BGP Scope configuration mode.

**Usage Guide**

This command is used to configure the interval for the BGP timely scan; it takes effect when **bgp scan-rib enable** is configured.

**Configuration Examples**

The following example configures the interval for the BGP timely scan.

```
Ruijie(config-router)# bgp scan-time 30
```

**Related****Commands**

| Command                    | Description                                      |
|----------------------------|--------------------------------------------------|
| <b>bgp scan-rib enable</b> | Enables timely scan of the routing table by BGP. |

**Platform****Description** None

## 5.69 bgp shutdown

Use this command to shut down all BGP connections.

**bgp shutdown**

Use this command to shut down all BGP connections gracefully.

**bgp shutdown graceful** [ **community** *value* ] [ **delay** *time* ]

Use the **no** form or **default** form of this command to restore the default settings.

**no bgp shutdown**

**default bgp shutdown**

| Parameter<br>Description | Parameter                     | Description                                                                                                                            |
|--------------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
|                          | <b>graceful</b>               | Shuts down BGP connections gracefully.                                                                                                 |
|                          | <b>community</b> <i>value</i> | Indicates the community value carried in the route sent to the neighbor. Format: AA:NN or a number in the range of 0 to 4,294,967,295. |
|                          | <b>delay</b> <i>time</i>      | Indicates the delay time (in seconds) for shutting down BGP connections. The value range is from 1 to 65,535.                          |

**Defaults** By default, the BGP connections are not shut down.

**Command Mode** BGP configuration mode/BGP scope global configuration mode

**Usage Guide** This command will shut down the effective connections created by BGP and delete all the routes information.

If you enable the function on BGP configuration mode or BGP scope global configuration mode, all the BGP connections will be shut down.

If you enable the function on BGP IPv4 VRF address family configuration mode or BGP IPv6 VRF address family configuration mode, all the BGP connections on the corresponding VRF will be shut down.

The feature enables the device to advertise a route with the lowest priority (the value of **local-preference** is **0** or the value of **med** is 4,294,967,295) to a neighbor and carry the **gshut community** attribute in the route so that the neighbor updates routes and switch traffic to a backup link or other equivalent links in advance. The device shuts down the BGP connection with the neighbor after a period of time.

**Configuration** The following example disables BGP connections globally.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp shutdown
```

The following example disables global BGP connections gracefully.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp shutdown graceful
```

**Platform Description** N/A

## 5.70 bgp sourced-paths

Use this command to enable the function of importing routes with multiple paths or next hops from other protocol modules. Use the **no** form of this command to disable the function of importing routes with multiple

paths or next hops from other protocol modules. Use the **default** form of this command to restore the default settings.

**bgp sourced-paths** *protocol-type* **all**

**no bgp sourced-paths** *protocol-type* **all**

**default bgp sourced-paths** *protocol-type* **all**

| Parameter Description | Parameter            | Description                                                                                                                                                                                                                                                                                                         |
|-----------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>protocol-type</i> | Source protocol type of a redistributed route: <ul style="list-style-type: none"> <li>● connected</li> <li>● static</li> <li>● rip</li> <li>● ospf</li> <li>● isis</li> <li>● arp-host (host route converted by ARP)</li> <li>● nd-route(route converted by ND)</li> <li>● aggregate (aggregation route)</li> </ul> |

**Defaults** Only routes with a single path or next hop can be imported from other protocol modules by default.

**Command Mode** BGP configuration mode, BGP IPv4 Unicast/VRF address family configuration mode, BGP IPv6 Unicast/VRF address family configuration mode, BGP scope global configuration mode

**Default Level** 14

**Usage Guide** This command needs to be used together with the redistribution command to import routes with multiple next hops from other protocols to BGP.

**Configuration Examples** The following example enables the function of importing static routes with multiple paths or next hops.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp sourced-paths static all
```

**Verification** Run the **show running-config** command to display the BGP configurations.

## 5.71 bgp tcp-source-check disable

Use this command to configure BGP's TCP source check function. Use **no** form of this command to disable this function.

**bgp tcp-source-check disable**

**no bgp tcp-source-check disable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** This function is enabled by default.

**Command Mode** BGP configuration mode/BGP scope global configuration mode

**Usage Guide** After TCP source check function is disabled, all TCP connection requests will be received. After TCP connection is established, if no neighbor peer is configured on the local device, Notification packet will be send to refuse the BGP connection.

**Configuration Examples** The following example configures BGP's TCP source check function.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp tcp-source-check disable
```

| Configuration Examples | Command    | Description           |
|------------------------|------------|-----------------------|
|                        | router bgp | Enables BGP protocol. |

**Platform** N/A

**Description**

## 5.72 bgp timer accuracy-control

Use this command to configure BGP's internal timer accuracy control. Use **no** form of this command to restore the default setting.

**bgp timer accuracy-control**

**no bgp timer accuracy-control**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode/BGP scope global configuration mode

**Usage Guide** By default, a deviation from the given time will occur on the BGP protocol's timer to prevent concurrent overtime of many timers. You can use this command to configure BGP protocol's timer to strictly implement the given time. It is recommended disabling this function unless necessary.

**Configuration Examples** The following example configures BGP's internal timer accuracy control.

```
Ruijie(config)# router bgp 65000
```

```
Ruijie(config-router)# bgp timer accuracy-control
```

### Configuration Examples

| Command           | Description           |
|-------------------|-----------------------|
| <b>router bgp</b> | Enables BGP protocol. |

**Platform** N/A

### Description

## 5.73 bgp update-delay

Use this command to set the maximum delay time of the BGP Speaker before sending the first updating information to neighbors. The **no** form of the command restores it to the default value. During the BGP graceful-restart, this command is used to update the delay time.

**bgp update-delay** *delay-time*

**no bgp update-delay**

### Parameter Description

| Parameter         | Description                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>delay-time</i> | Maximum delay time of the BGP Speaker before sending its route updating information, in the range from 0 to 3600 in the unit of seconds, 120 seconds by default. For BGP graceful-restart, it is the maximum time of waiting to receive the EOR message of all neighbors, in the range from 1 to 3600 in the unit of seconds. |

**Defaults** The default is 120.

### Command

**Mode** BGP configuration mode/BGP scope global configuration mode

### Usage Guide

With the BGP starting up, it first waits some time to connect with its neighbors, and then sends the updating message to these neighbors. After connecting with neighbors, the BGP does not send the updating message to them immediately, but waits some time to receive the updating routing message from all neighbors and then performs routing optimization calculation and finally advertises the route updating message to its neighbors, which improves the convergence time and reduces the calculation consumption. If the software sends the route updating information to its neighbors immediately, it may send the information again when it receives more optimized routes from other neighbors.

The **bgp update-delay** command is used to adjust the initial waiting time of the software, which is the maximum time, from establishing the connection with the first neighbor to performing the routing optimization calculation and sending the route advertisement. When the BGP graceful-restart is enabled, this command is also used to set the maximum waiting time to receive EOR messages from all neighbors. You can increase this value if there are many neighbors or the routing information of the neighbors is huge. If the number of neighbors is 100 and the average amount of routes is 5000, the update sending time that each neighbor completes all the routing is 1 second,

then the update of all the routing needs 100 seconds; if the number of neighbors increases to 200, the Update Delay time can be set to 240 seconds, ensuring that all the routing can be updated with the Update Delay period. The specific time is also related to data transmission rate.

The following example sets the update-delay time to 200 seconds.

**Configuration****Examples**

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp graceful-restart
Ruijie(config-router)# bgp update-delay 200
```

**Related****Commands**

| Command                     | Description                       |
|-----------------------------|-----------------------------------|
| <b>bgp graceful-restart</b> | Enables the BGP graceful-restart. |

**Platform****Description**

None

## 5.74 bgp update-rate

Use this command to set the maximum routes number sent by BGP Speaker per second. Use the **no** or **default** form of this command to restore the default settings.

**bgp update-rate** *route-number*

**no bgp update-rate**

**default bgp update-rate**

**Parameter****Description**

| Parameter           | Description                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------|
| <i>route-number</i> | Indicates the maximum routes number sent by BGP Speaker per second. The range is from 10 to 4294967295. |

**Defaults**

The function is disabled by default.

**Command****Mode**

BGP configuration mode/ BGP scope global configuration mode.

**Usage****Guide**

By default, BGP will directly calculate the routes which it receives and send the routes to the delivery queue of each neighbor, Run **bgp update-rate** command to set the maximum routes number. For example, if the maximum routes can be sent per second is 100 routes, and the BGP route table contains 200 routes, then the 200 routes will be sent to the delivery queue of its neighbor by two times analysis (Refers to the analysis on route sending, for example, 100 routes exist, but only 80 routes in it are suitable for sending).

**Configuration****Examples**

The following example set the maximum routes number sent by BGP Speaker per second to 100.

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp update-rate 100
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform****Description** N/A

## 5.75 bgp upgrade-cli

Use this command to set the BGP CLI display mode. Use the **no** or **default** form of this command to restore the default settings.

**bgp upgrade-cli { af-mode | scope-mode }**

**no bgp upgrade-cli { af-mode | scope-mode }**

**default bgp upgrade-cli { af-mode | scope-mode }**

| Parameter<br>Description | Parameter         | Description                                            |
|--------------------------|-------------------|--------------------------------------------------------|
|                          | <b>af-mode</b>    | CLI is displayed in address family configuration mode. |
|                          | <b>scope-mode</b> | CLI is displayed in scope configuration mode.          |

**Defaults**

The default is **af-mode**. When you execute the **scope** command, the display mode is switched to scope configuration mode automatically.

**Command****Mode** BGP configuration mode, BGP scope global configuration mode.**Usage****Guide**

When the display mode is switched to the scope global configuration mode, all CLI commands will be displayed either in the scope configuration mode or the address-family mode that under the scope configuration mode.

**Configuration****Examples**

The following example sets the scope global configuration mode as the BGP CLI display mode.

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp upgrade-cli scope-mode
```

## 5.76 bmp server

Use this command to configure the bmp server example and enter the bmp configuration mode. Use the **no** form of this command to close the bmp server example. Use the **default** form of this command to restore the default settings.

**bmp server** *server-number*

**no bmp server** *server-number*

**default bmp server** *server-number*

| Parameter   | Parameter            | Description                                                            |
|-------------|----------------------|------------------------------------------------------------------------|
| Description | <i>server-number</i> | Configures the example number of bmp monitoring server.<br>Range: 1-8. |

**Defaults** The default BMP protocol is closed.

**Command**

**Mode** Global configuration mode

**Default**

**Level** 14

**Usage**

**Guide** Use this command to enable the BMP protocol

Enable the BMP protocol and specify the example number.

**Configuration**

**Examples**

```
Ruijie(config)# bmp server 1  
  
Ruijie(config-bmpsrvr)#
```

**Verification** Run the **show running-config** command to check the BGP configuration.

## 5.77 buffer-size

Use this command to configure the max bytes of packets in buffer. Use the **no** or **default** form of this command to restore the default settings.

**buffer-size** *maximum*

**no buffer-size**

**default buffer-size**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b>            | <div> <div><i>maximum</i></div> <div>Configure the max bytes of packet in buffer for BMP instance.<br/>Range: 40960-4294967295</div> </div>                                                                                                                                                                                                                                                                       |
| <b>Defaults</b>               | The max bytes is not configured by default.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Command Mode</b>           | BMP configuration mode                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default Level</b>          | 14                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Usage Guide</b>            | <p>Use this command to configure the max bytes of packet in buffer for BMP instance. When the device can not forward monitor packets due to insufficient server memory or other reasons, these packets will continually occupy the memory space, so there should be a limit of the max bytes of packet in buffer. When bytes reach the limit, the session with BMP server will be reset to release the space.</p> |
| <b>Configuration Examples</b> | <p>Enable the BMP protocol, specify the instance number and set the max bytes of packet in buffer.</p> <pre>Ruijie(config)# bmp server 1 Ruijie(config-bmpsrvr)#buffer-size 409600000 Ruijie(config-bmpsrvr)#</pre>                                                                                                                                                                                               |
| <b>Verification</b>           | Run the <b>show running-config</b> command to check the BGP configuration.                                                                                                                                                                                                                                                                                                                                        |

## 5.78 clear bgp advertise lowest-priority on-startup

Use this command to restore the priority of advertised routes.

**clear bgp [ instance *as-num* ] advertise lowest-priority on-startup**

| <b>Parameter Description</b> | Parameter            | Description                                                                                                                                                                                                                  |
|------------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <b>instance</b>      | Specify the instance                                                                                                                                                                                                         |
|                              | <i>as-num</i>        | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <b>Defaults</b>              | N/A                  |                                                                                                                                                                                                                              |
| <b>Command Mode</b>          | Privileged EXEC mode |                                                                                                                                                                                                                              |

**Usage Guide** Run **bgp advertise lowest-priority on-startup** command to adjust the priority of advertised routes to the lowest upon device restart. Run **clear bgp advertise lowest-priority on-startup** command to restore the priority of advertised routes.

## 5.81 clear bgp all update-group

Use this command to reset sessions of all members in an update-group.

**clear bgp** [ **instance** *as-num* ] **all update-group** [ *update-group-index* | *peer-address* ] [ **soft** ] [ **in** | **out** ]

| Parameter Description | Parameter                 | Description                                                                                                                                                                                                                  |
|-----------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset.                                                                                                                                   |
|                       | <b>instance</b>           | Specify the instance                                                                                                                                                                                                         |
|                       | <i>as-num</i>             | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
|                       | <i>peer-address</i>       | Specifies the update-group, to which a peer whose session needs to be reset belongs.                                                                                                                                         |
|                       | -                         | Resets BGP sessions directly if no option is carried.                                                                                                                                                                        |
|                       | <b>in</b>                 | Resets received routing information.                                                                                                                                                                                         |
|                       | <b>out</b>                | Resets distributed routing information.                                                                                                                                                                                      |
|                       | <b>soft</b>               | Soft-resets sent and received routing information.                                                                                                                                                                           |
|                       | <b>soft in</b>            | Soft-resets received routing information.                                                                                                                                                                                    |
|                       | <b>soft out</b>           | Soft-resets distributed routing information.                                                                                                                                                                                 |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to reset BGP sessions of all members in an update-group.

**Configuration Example** The following example resets routing information received by all peers in an update group to which the peer with the IP address of 1.1.1.1 belongs.

```
Ruijie# clear bgp all update-group 1.1.1.1 in
```

## 5.82 clear bgp ipv4 unicast

Use this command to reset BGP IPv4 unicast address families. The reset content is determined by further parameters.

**clear bgp** [ **instance** *as-num* ] **ipv4 unicast** [ **vrf** *vrf-name* ] { \* | *as-number* | *neighbor-address* }  
[ **soft** ] [ **in** | **out** ]

### Parameter Description

| Parameter               | Description                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>         | VRF name                                                                                                                                                                                                                     |
| <b>instance</b>         | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>           | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| *                       | Resets all peer group sessions under address families.                                                                                                                                                                       |
| <i>as-number</i>        | Resets sessions with all members in the specified AS.                                                                                                                                                                        |
| <i>neighbor-address</i> | Resets sessions with the specified peer.                                                                                                                                                                                     |
| <b>in</b>               | Resets received route information.                                                                                                                                                                                           |
| <b>out</b>              | Resets allocated route information.                                                                                                                                                                                          |
| <b>soft</b>             | Soft-resets received and sent route information.                                                                                                                                                                             |
| <b>soft in</b>          | Soft-resets received route information.                                                                                                                                                                                      |
| <b>soft out</b>         | Soft-resets allocated route information.                                                                                                                                                                                     |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is the same as **clear ip bgp** in terms of the function and parameters.

**Configuration Examples** N/A

## 5.83 clear bgp ipv4 unicast dampening

Use this command to clear the flap information and disable route dampening.

**clear bgp [ instance *as-num* ] ipv4 unicast [ vrf *vrf-name* ] dampening [ *ip-address* [ *mask* ] ]**

### Parameter Description

| Parameter       | Description                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | VRF instance name                                                                                                                                                                                                            |
| <b>instance</b> | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>   | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| -               | Clears the flap information of all routes.                                                                                                                                                                                   |
| <i>address</i>  | IP address                                                                                                                                                                                                                   |
| <i>mask</i>     | Mask                                                                                                                                                                                                                         |

**Defaults** N/A

### Command

**Mode** Privileged EXEC mode

**Usage** This command is used to clear the BGP route dampening information and release suppressed routes. This command can be used to restart the BGP route dampening.

**Configuration** The following example clears the flap information and disables route dampening.

**Examples** Ruijie# clear ip bgp dampening 192.168.0.0 255.255.0.0

**Defaults** N/A

#### Command

**Mode** Privileged EXEC mode

#### Usage

#### Guide

This command can be used only to clear the statistics of unsuppressed routes. It does not release the suppressed routes. To clear all route statistics and release the suppressed routes, run the **clear ip bgp dampening** command.

#### Configuration

The following example clears the route flap information.

#### Examples

```
Ruijie# clear bgp ipv4 unicast flap-statistics
```

## 5.88 clear bgp ipv4 unicast update-group

Use this command to reset sessions of all members in an update-group in the IPv4 unicast address family.

**clear bgp** [ **instance** *as-num* ] **ipv4 unicast** [ **vrf** *vrf-name* ] **update-group** [ *update-group-index* | *peer-address* ] [ **soft** ] [ **in** | **out** ]

| Parameter   | Parameter                 | Description                                                                                                                                                                                                                  |
|-------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>vrf-name</i>           | Specifies the name of a VRF instance. A global VRF instance is used if no VRF instance name is entered.                                                                                                                      |
|             | <b>instance</b>           | Specify the instance                                                                                                                                                                                                         |
|             | <i>as-num</i>             | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
|             | <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset.                                                                                                                                   |
|             | <i>peer-address</i>       | Specifies the update-group, to which a peer whose session needs to be reset belongs.                                                                                                                                         |
|             | -                         | Resets BGP sessions directly if no option is carried.                                                                                                                                                                        |
|             | <b>in</b>                 | Resets received routing information.                                                                                                                                                                                         |
|             | <b>out</b>                | Resets distributed routing information.                                                                                                                                                                                      |
|             | <b>soft</b>               | Soft-resets sent and received routing information.                                                                                                                                                                           |
|             | <b>soft in</b>            | Soft-resets received routing information.                                                                                                                                                                                    |
|             | <b>soft out</b>           | Soft-resets distributed routing information.                                                                                                                                                                                 |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to reset BGP sessions of all members in an update-group in the IPv4 unicast address family.

**Configuration Example** The following example resets routing information received by all peers in an update group to which the peer with the IP address of 1.1.1.1 in the IPv4 unicast address family belongs.

```
Ruijie# clear bgp ipv4 unicast update-group 1.1.1.1 in
```

## 5.89 clear bgp ipv6 unicast

Use this command to reset BGP's IPv6 unicast address families.

**clear bgp** [ **instance** *as-num* ] **ipv6 unicast** [ **vrf** *vrf-name* ] { \* | *as-number* | *neighbor-address* }  
[ **soft** ] [ **in** | **out** ]

### Parameter Description

| Parameter               | Description                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>         | VRF name                                                                                                                                                                                                                     |
| <b>instance</b>         | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>           | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| *                       | Resets all peer group sessions under address families.                                                                                                                                                                       |
| <i>as-number</i>        | Resets sessions with all members in the specified AS.<br>In 10.4(3) or a later version, adds support for 4-byte AS numbers. The new AS number ranges from 1 to 4294967295, or 1 and 65535.65535 in the dotted mode.          |
| <i>neighbor-address</i> | Resets sessions with the specified peer.                                                                                                                                                                                     |
| <b>in</b>               | Resets received route information.                                                                                                                                                                                           |
| <b>out</b>              | Resets allocated route information.                                                                                                                                                                                          |
| <b>soft</b>             | Soft-resets received and sent route information.                                                                                                                                                                             |
| <b>soft in</b>          | Soft-resets received route information.                                                                                                                                                                                      |
| <b>soft out</b>         | Soft-resets allocated route information.                                                                                                                                                                                     |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** The function is similar with **clear bgp ipv4 unicast**, but applies to different address families.

**Configuration** -

**Description**

## 5.92 clear bgp ipv6 unicast flap-statistics

Use this command to clear IPv6 unicast address families' route flap statistics.

**clear bgp** [ **instance** *as-num* ] **ipv6 unicast** [ **vrf** *vrf-name* ] **flap-statistics** [ *address* [ *mask* ] ]

| Parameter<br>Description | Parameter       | Description                                                                                                                                                                                                                  |
|--------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>vrf-name</i> | VRF name                                                                                                                                                                                                                     |
|                          | <b>instance</b> | Specify the instance                                                                                                                                                                                                         |
|                          | <i>as-num</i>   | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
|                          | -               | Clears all route information's flap information.                                                                                                                                                                             |
|                          | <i>address</i>  | IP address                                                                                                                                                                                                                   |
|                          | <i>mask</i>     | Mask code                                                                                                                                                                                                                    |
|                          |                 |                                                                                                                                                                                                                              |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** This command can only clear statistics of routes that are not damped and will not relieve damped routes. To clear statistics of all route information and relieve damped routes, use the **clear bgp ipv4 unicast dampening** command.

**Configuration Examples** The following example clears IPv6 unicast address families' route flap statistics.

**Examples** Ruijie# clear bgp ipv6 unicast flap-statistics

| Configuration<br>Examples | Command              | Description                                                         |
|---------------------------|----------------------|---------------------------------------------------------------------|
|                           | <b>bgp dampening</b> | Enables the route dampening function and sets dampening parameters. |
|                           | <b>show ip bgp</b>   | Displays BGP route entries.                                         |

**Description**

## 5.93 clear bgp ipv6 unicast peer-group

Use this command to reset sessions with all members in the peer group.

**clear bgp** [ **instance** *as-num* ] **ipv6 unicast** [ **vrf** *vrf-name* ] **peer-group** *peer-group-name* [ **soft** ] [ **in** | **out** ]

**Parameter  
Description**

| Parameter              | Description                                                                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>        | VRF name                                                                                                                                                                                                                     |
| <b>instance</b>        | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>          | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <i>peer-group-name</i> | Peer group name                                                                                                                                                                                                              |
| <b>in</b>              | Resets received route information.                                                                                                                                                                                           |
| <b>out</b>             | Resets allocated route information.                                                                                                                                                                                          |
| <b>soft</b>            | Soft-resets received and sent route information.                                                                                                                                                                             |
| <b>soft in</b>         | Soft-resets received route information.                                                                                                                                                                                      |
| <b>soft out</b>        | Soft-resets allocated route information.                                                                                                                                                                                     |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to reset BGP sessions with all members in the peer group.

**Configuration Examples** The following example resets sessions with all members in the peer group.

**Examples** Ruijie# clear bgp ipv6 unicast peer-group my-group in

### Description

## 5.95 clear bgp ipv6 unicast update-group

Use this command to reset sessions of all members in an update-group in the IPv6 unicast address family.

**clear bgp** [ **instance** *as-num* ] **ipv6 unicast** [ **vrf** *vrf-name* ] **update-group** [ *update-group-index* | *neighbor-address* ] [ **soft** ] [ **in** | **out** ]

### Parameter Description

| Parameter       | Description                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | Specifies the name of a VRF instance. A global VRF instance is used if no VRF instance name is entered. |

|                           |                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>           | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>             | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset.                                                                                                                                   |
| <i>neighbor-address</i>   | Specifies the update-group, to which a peer whose session needs to be reset belongs.                                                                                                                                         |
| -                         | Resets BGP sessions directly if no option is carried.                                                                                                                                                                        |
| <b>in</b>                 | Resets received routing information.                                                                                                                                                                                         |
| <b>out</b>                | Resets distributed routing information.                                                                                                                                                                                      |
| <b>soft</b>               | Soft-resets sent and received routing information.                                                                                                                                                                           |
| <b>soft in</b>            | Soft-resets received routing information.                                                                                                                                                                                    |
| <b>soft out</b>           | Soft-resets distributed routing information.                                                                                                                                                                                 |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to reset BGP sessions of all members in an update-group in the IPv6 unicast address family.

**Configuration Example** The following example resets routing information received by all peers in an update group to which the peer with the IP address of 1111::1111 in the IPv6 unicast address family belongs.

```
Ruijie# clear bgp ipv6 unicast update-group 1111::1111 in
```

## 5.96 clear bgp l2vpn evpn

Use this command to reset BGP EVPN address families.

**clear bgp [ instance *as-num* ] l2vpn evpn { \* | *as-number* | *neighbor-address* } [ soft ] [ in | out ]**

| Parameter Description | Parameter        | Description                                                                                                                                                                                                                  |
|-----------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | *                | Resets all peer group sessions under address families.                                                                                                                                                                       |
|                       | <b>instance</b>  | Specify the instance                                                                                                                                                                                                         |
|                       | <i>as-num</i>    | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
|                       | <i>as-number</i> | Resets sessions with all members in the specified AS.<br>In 10.4(3) or a later version, adds support for 4-byte AS numbers. The                                                                                              |

|                         |                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------|
|                         | new AS number ranges from 1 to 4294967295, or 1 and 65535.65535 in the dotted mode. |
| <i>neighbor-address</i> | Resets sessions with the specified peer.                                            |
| <b>in</b>               | Resets received route information.                                                  |
| <b>out</b>              | Resets allocated route information.                                                 |
| <b>soft</b>             | Soft-resets received and sent route information.                                    |
| <b>soft in</b>          | Soft-resets received route information.                                             |
| <b>soft out</b>         | Soft-resets allocated route information.                                            |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** The function is similar with **clear bgp ipv4 unicast**, but applies to different address families.

**Configuration Examples** -

| <b>Configuration Examples</b> | Command                       | Description                                 |
|-------------------------------|-------------------------------|---------------------------------------------|
|                               | <b>clear bgp ipv4 unicast</b> | Resets BGP's IPv4 unicast address families. |

**Platform Description** -

## 5.97 clear bgp l2vpn evpn dampening

Use this command to clear flap information and disable route dampening.

**clear bgp [ instance *as-num* ] l2vpn evpn dampening**

| <b>Parameter Description</b> | Parameter       | Description                                                                                                                                                                                                                  |
|------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <b>instance</b> | Specify the instance                                                                                                                                                                                                         |
|                              | <i>as-num</i>   | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** You can use this command to clear BGP's route flap information and relieve damped routes. The command can restart BGP's route flap.

**Configuration** The following example clears flap information and disables route dampening.

**Examples** Ruijie# clear bgp l2vpn evpn dampening

**Platform** N/A

**Description**

## 5.98 clear bgp l2vpn evpn external

Use this command to reset all EBGp connection of BGP EVPN address families.

**clear bgp [ instance *as-num* ] l2vpn evpn external [ soft ] [ in | out ]**

|                          | <b>soft</b>     | Soft-resets received and sent route information.                                                                                                                                                                             |
|                          | <b>soft in</b>  | Soft-resets received route information.                                                                                                                                                                                      |
|                          | <b>soft out</b> | Soft-resets allocated route information.                                                                                                                                                                                     |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** You can use this command to reset all the specified external BGP connection.

**Configuration** The following example resets all EBGp connection of L2VPN EVPN address families.

**Examples** Ruijie# clear bgp l2vpn evpn external in

**Platform** N/A

**Description**

## 5.99 clear bgp l2vpn evpn flap-statistics

Use this command to clear BGP EVPN address families' route flap statistics.

**clear bgp** [ **instance** *as-num* ] **l2vpn evpn flap-statistics**

### Parameter Description

| Parameter       | Description                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>   | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command can only clear statistics of routes that are not damped and will not relieve damped routes. To clear statistics of all route information and relieve damped routes, use the **clear bgp l2vpn evpn dampening** command.

**Configuration** The following example clears L2VPN EVPN address families' route flap statistics.

**Examples** Ruijie# clear bgp l2vpn evpn flap-statistics

**Platform** N/A

**Description**

## 5.100 clear bgp l2vpn evpn peer-group

Use this command to reset sessions of all members in the peer group.

**clear bgp** [ **instance** *as-num* ] **l2vpn evpn peer-group** *peer-group-name* [ **soft** ] [ **in** | **out** ]

### Parameter Description

| Parameter              | Description                                                                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>peer-group-name</i> | Peer group name                                                                                                                                                                                                              |
| <b>instance</b>        | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>          | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <b>in</b>              | Resets received route information.                                                                                                                                                                                           |

|                 |                                                  |
|-----------------|--------------------------------------------------|
| <b>out</b>      | Resets allocated route information.              |
| <b>soft</b>     | Soft-resets received and sent route information. |
| <b>soft in</b>  | Soft-resets received route information.          |
| <b>soft out</b> | Soft-resets allocated route information.         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to reset BGP sessions of all members in the peer group.

**Configuration Examples** The following example displays that the L2VPN EVPN address family resets received route information of all members in the peer group my-group.

```
Ruijie# clear bgp l2vpn evpn peer-group my-group in
```

**Platform** N/A

**Description**

## 5.101 clear bgp l2vpn evpn update-group

Use this command to reset sessions of all members in an update-group of L2VPN EVPN address family.

**clear bgp** [ **instance** *as-num* ] **l2vpn evpn update-group** [ *update-group-index* | *neighbor-address* ] [ **soft** ] [ **in** | **out** ]

**Parameter Description**

| Parameter                 | Description                                                                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>           | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>             | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset.                                                                                                                                   |
| <i>Neighbor-address</i>   | Specifies the update-group, to which a peer whose session needs to be reset belongs.                                                                                                                                         |
| -                         | Resets BGP sessions directly if no option is carried.                                                                                                                                                                        |
| <b>in</b>                 | Resets received routing information.                                                                                                                                                                                         |
| <b>out</b>                | Resets distributed routing information.                                                                                                                                                                                      |
| <b>soft</b>               | Soft-resets sent and received routing information.                                                                                                                                                                           |
| <b>soft in</b>            | Soft-resets received routing information.                                                                                                                                                                                    |
| <b>soft out</b>           | Soft-resets distributed routing information.                                                                                                                                                                                 |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to reset BGP sessions of all members in an update-group of L2VPN EVPN address family.

**Configuration Example** The following example resets routing information received by all peers in an update group of L2VPN EVPN address family to which the peer with the IP address of 1.1.1.1 belongs.

```
Ruijie# clear bgp l2vpn evpn update-group 1.1.1.1 in
```

## 5.102 clear bmp

Use this command to reset the BGP protocol. The reset content is determined by consequent parameters.

**clear bmp { all | server *server-number* }**

| Parameter Description | Parameter            | Description                                   |
|-----------------------|----------------------|-----------------------------------------------|
|                       | all                  | Resets all BMP servers                        |
|                       | <i>server-number</i> | Resets the specified BMP servers. Range: 1-8. |

**Defaults** N/A

**Command Mode** Privileged mode

**Usage Guide** Use this command to disconnect from the BMP server and then reconnect to it.

## 5.103 clear evpn conflict mac

Use this command to clear MAC information and other statistics of conflicts occurring in EVPN.

**clear evpn conflict mac [ *vni-id* ]**

| Parameter Description | Parameter     | Description                                                                              |
|-----------------------|---------------|------------------------------------------------------------------------------------------|
|                       | <i>vni-id</i> | Clears MAC information and other statistics of conflicts occurring on a specified L2VNI. |

## 5.104 clear ip bgp

Use this command to reset the BGP session.

**clear ip bgp** [ **instance** *as-num* ] [ **vrf** *vrf-name* ] { \* | *as-number* / *neighbor-address* } [ **soft** ] [ **in** | **out** ]

### Parameter Description

| Parameter               | Description                                                                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>         | VRF name.                                                                                                                                                                                                                                       |
| <b>instance</b>         | Specify the instance                                                                                                                                                                                                                            |
| <i>as-num</i>           | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode.                    |
| *                       | Resets all the current BGP sessions and the OVERFLOW status of BGP ipv4 unicast address family.                                                                                                                                                 |
| <i>neighbor-address</i> | Resets the BGP session with the specified peer (IPv4 or IPv6).                                                                                                                                                                                  |
| <i>as number</i>        | Resets sessions with all members in the specified AS. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <b>in</b>               | Reset the received routing information.                                                                                                                                                                                                         |
| <b>out</b>              | Reset the redistributed routing information.                                                                                                                                                                                                    |
| <b>soft</b>             | Soft-reset all routing information received/sent from/to the specified peer                                                                                                                                                                     |
| <b>soft in</b>          | Soft-reset the received routing information.                                                                                                                                                                                                    |
| <b>soft out</b>         | Soft-reset the distributed routing information.                                                                                                                                                                                                 |

**Defaults** N/A

### Command

**Mode** Privileged EXEC mode

At any time, once the routing policy or BGP configuration changes, an effective way must be available to implement the new routing policy or configuration. Traditional measure is to close the BGP connection and establish a new one.

This product supports implementing a new routing strategy without closing the BGP session connection by soft-resetting BGP.

### Usage

### Guide

For the peer that does not support the route refresh function, you may run the **neighbor soft-reconfiguration inbound** command to keep a copy of original routing information of every specified BGP peer on the local BGP speaker. This will consume some resources.

You can use the **show ip bgp neighbors** command to see whether the BGP peer supports the route refresh function. If it is supported, you need not to execute the **neighbor**

**soft-reconfiguration inbound** command when the inbound routing strategy changes.

-  All connected BGP routers must support the route refresh function to execute this command. This product supports the route refresh function.

**Configuration** The following example resets the BGP session.

**Examples** Ruijie# clear bgp ipv4 unicast \*

## 5.106 clear ip bgp external

Use this command to reset all EBGp connections.

**clear ip bgp [ instance *as-num* ] [ vrf *vrf-name* ] external [ soft ] [ in | out ]**

Parameter  
Description

| Parameter       | Description                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | VRF name.                                                                                                                                                                                                                    |
| <b>instance</b> | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>   | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <b>in</b>       | Reset the received routing information.                                                                                                                                                                                      |
| <b>out</b>      | Reset the redistributed routing information.                                                                                                                                                                                 |
| <b>soft in</b>  | Soft-resets the received routing information.                                                                                                                                                                                |
| <b>soft out</b> | Soft-resets the distributed routing information.                                                                                                                                                                             |

Defaults N/A

Command

Mode Privileged EXEC mode

Usage

Guide This command is used to reset the specified external BGP connection.

Configuration The following example resets all EBGp connections.

Examples

```
Ruijie# clear ip bgp external in
```

## 5.107 clear ip bgp flap-statistics

Use this command to clear the routes vibration statistics of the IPv4 unicast address family.

**clear ip bgp** [ **instance** *as-num* ] [ **vrf** *vrf-name* ] **flap-statistics** [ *ip-address* [ *mask* ] ]

### Parameter Description

| Parameter       | Description                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | VRF name.                                                                                                                                                                                                                    |
| <b>instance</b> | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>   | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <i>address</i>  | IP address                                                                                                                                                                                                                   |
| <i>Mask</i>     | Mask                                                                                                                                                                                                                         |

**Defaults** N/A

### Command

**Mode** Privileged EXEC mode

### Usage

#### Guide

This command can be used only to clear statistics of unsuppressed routes. It does not release the suppressed routes. To clear all route statistics and release the suppressed routes, run the **clear ip bgp dampening** command.

### Configuration

The following example clears the routes vibration statistics of the IPv4 unicast address family.

### Examples

```
Ruijie# clear ip bgp flap-statistics
```

### Related Commands

|----------------------|---------------------------------------------------------------------|
| <b>bgp dampening</b> | Enables the route dampening function and sets dampening parameters. |
| <b>show ip bgp</b>   | Displays the BGP route entry.                                       |

### Platform

**Description** None

## 5.108 clear ip bgp peer-group

Use this command to reset the session with all members in the peer group.

**clear ip bgp** [ **instance** *as-num* ] [ **vrf** *vrf-name* ] **peer-group** *peer-group-name* [ **soft** ] [ **in** | **out** ]

### Parameter Description

| Parameter       | Description          |
|-----------------|----------------------|
| <i>vrf-name</i> | VRF name.            |
| <b>instance</b> | Specify the instance |

|                        |                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-num</i>          | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <i>peer-group-name</i> | Name of the peer group                                                                                                                                                                                                       |
| <b>in</b>              | Reset the received routing information.                                                                                                                                                                                      |
| <b>out</b>             | Reset the redistributed routing information.                                                                                                                                                                                 |
| <b>soft</b>            | Soft-resets all routing information received/sent from/to the specified peer                                                                                                                                                 |
| <b>soft in</b>         | Soft-resets the received routing information.                                                                                                                                                                                |
| <b>soft out</b>        | Soft-resets the distributed routing information.                                                                                                                                                                             |

**Defaults** N/A

#### Command

**Mode** Privileged EXEC mode

#### Usage

**Guide** This command resets the BGP session with all members in the peer group.

**Configuration** The following example resets the session with all members in the peer group.

**Examples** Ruijie# clear ip bgp peer-group my-group in

## 5.110 clear ip bgp update-group

Use this command to reset sessions of all members in an update-group in the IPv4 unicast address family.

**clear ip bgp** [ **instance** *as-num* ] [ **vrf** *vrf-name* ] **update-group** [ *update-group-index* | *neighbor-address* ]  
[ **soft** ] [ **in** | **out** ]

**Parameter  
Description**

| Parameter                 | Description                                                                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>           | Specifies the name of a VRF instance. A global VRF instance is used if no VRF instance name is entered.                                                                                                                      |
| <b>instance</b>           | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>             | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset.                                                                                                                                   |
| <i>neighbor-address</i>   | Specifies the update-group, to which a peer whose session needs to be reset belongs.                                                                                                                                         |
| -                         | Resets BGP sessions directly if no option is carried.                                                                                                                                                                        |
| <b>in</b>                 | Resets received routing information.                                                                                                                                                                                         |
| <b>out</b>                | Resets distributed routing information.                                                                                                                                                                                      |
| <b>soft</b>               | Soft-resets sent and received routing information.                                                                                                                                                                           |

|                 |                                              |
|-----------------|----------------------------------------------|
| <b>soft in</b>  | Soft-resets received routing information.    |
| <b>soft out</b> | Soft-resets distributed routing information. |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to reset BGP sessions of all members in an update-group in the IPv4 unicast address family.

**Configuration Example** The following example resets routing information received by all peers in an update group to which the peer with the IP address of 1.1.1.1 in the IPv4 unicast address family belongs.

```
Ruijie# clear ip bgp update-group 1.1.1.1 in
```

## 5.111 default-information originate

Use this command to enable BGP to distribute the default route. Use the **no** form of this command to restore the default setting.

**default-information originate**

**[no] default-information originate**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP Scope configuration mode

**Usage Guide** This command is used to control whether the redistributed default route is effective, and this command needs to be configured together with the **redistribute** command. It takes effect only when a default route exists in the redistributed route.

This command is similar to the **network** command. The difference is that in the process of configuring the former, the **redistribute** command must be configured explicitly to redistribute the default route, only in this case, the redistributed default route is effective. For the later command, the IGP must have the default route.

**Configuration Examples** The following example enables BGP to distribute the default route.

```
Ruijie(config-router)# default-information originate
```

|------------------|----------------|-------------------------------------|
|                  | <b>network</b> | Configures routes to be advertised. |

|                     |                                         |
|---------------------|-----------------------------------------|
| <b>redistribute</b> | Redistributes routes of other protocol. |
|---------------------|-----------------------------------------|

**Platform****Description** None

## 5.112 default-metric

Use this command to set the metric for route redistribution. Use the **no** form of this command to restore the default setting.

**default-metric** *number***no default-metric**

| Parameter          | Parameter     | Description                                      |
|--------------------|---------------|--------------------------------------------------|
| <b>Description</b> | <i>number</i> | Metric number, in the range from 1 to 4294967295 |

**Defaults** No metric is set by default.**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP Scope configuration mode**Usage Guide** This command sets the metric of routes to be redistributed for integrity. The metric set by the command cannot cover that set by the redistribute metric command. The value is 0 when the default metric applies to redistributed connected routes.**Configuration Examples** The following example sets the metric for route redistribution.

```
Ruijie(config-router)# default-metric 45
```

## 5.114 distance bgp

Use this command to set different management distances for different types of BGP routes. Use the **no** form of this command to restore the default setting.

**distance bgp** *external-distance internal-distance local-distance*

**no distance bgp**

| Parameter                | Description                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>external-distance</i> | Route management distance learned from EBGp peers, in the range from 1 to 255                                                                                                                                                           |
| <i>internal-distance</i> | Route management distance learned from IBGP peers, in the range from 1 to 255                                                                                                                                                           |
| <i>local-distance</i>    | Specifies the management distance of route learned from peers. However, the optimal one can be learned from the IGP. In general, these routes are indicated by the Network Backdoor command.<br>The value is in the range from 1 to 255 |

The parameter defaults are as follows:

*external-distance* - 20

*internal-distance - 200*

*local-distance - 200*

**Command****Mode** BGP configuration mode/BGP scope global configuration mode

It is not recommended to change the management distance of the BGP route. If it is necessary, observe the following points:

**Usage****Guide**

- The management distance of "external-distance" must be shorter than those of other IGP routing protocols (such as OSPF and RIP);
- The internal-distance and local-distance should have longer management distances than other IGP routing protocols.

**Configuration**

The following example sets different management distances for different types of BGP routes.

**Examples**

```
Ruijie(config-router)# distance bgp 20 20 200
```

**Related  
Commands**

| Command                                      | Description                                                                                         |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <b>neighbor soft-reconfiguration inbound</b> | Restarts the BGP session and reserves the unchanged route information sent by the BGP peer (group). |
| <b>show ip bgp</b>                           | Displays the BGP route entry.                                                                       |

**Platform****Description** None

## 5.115 evpn

Use this command to enter EVPN configuration mode. Use the **no** or **restore** form of this command to restore the default settings.

**evpn****no evpn****default evpn****Parameter****Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

By default, the EVPN configuration mode is disabled.

**Command****Mode** Global configuration mode**Usage****Guide**

Use this command to enter EVPN configuration mode. Use the **exit** command to exit the EVPN configuration mode

**Configuration**

The following example enters EVPN configuration mode.

**Examples** Ruijie(config)# evpn

**Platform**

**Description** N/A

## 5.116 exit-address-family

Use this command to exit BGP address-family configuration mode.

### exit-address-family

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command**

**Mode** BGP address-family configuration mode

**Usage** This command can be used to exit from various address-family modes of BGP to BGP configuration mode.

**Configuration** The following example exits the BGP address-family configuration mode.

**Examples** Ruijie(config-router-af)#exit-address-family

| Related  | Command             | Description                                    |
|----------|---------------------|------------------------------------------------|
| Commands | address-family ipv4 | Enters IPv4 address family configuration mode. |

**Platform**

## 5.117 export map(EVPN VNI)

Use this command to configure the route map for exporting the extended community attribute of EVPN routes from the local device to the remote device. Use the **no** form of this command to delete the route map for exporting the extended community attribute of EVPN routes from the local device to the remote device. Use the **default** form of this command to restore the default settings.

**export map** *route-map-name*

**no export map**

**default export map**

| Parameter   | Parameter             | Description           |
|-------------|-----------------------|-----------------------|
| Description | <i>route-map-name</i> | Name of the route map |

|                               |                                                                                                                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | No route map is configured for exporting the extended community attribute by default.                                                                                                                                                                                  |
| <b>Command Mode</b>           | EVPN VNI configuration mode.                                                                                                                                                                                                                                           |
| <b>Default Level</b>          | 14                                                                                                                                                                                                                                                                     |
| <b>Usage Guide</b>            | <p>This command is used to modify the extended community attribute advertised by a type 5 route converted from a local EVPN route or IP route.</p> <p>This command supports only one route map, and the old configuration is overwritten by the new configuration.</p> |
| <b>Configuration Examples</b> | <p>The following example configures a route map for exporting the extended community attribute associated with map1 on VNI 1.</p> <pre>Ruijie(config)# evpn Ruijie(config-evpn)# vni 1 Ruijie(config-evpn-vni)# export map map1</pre>                                  |
| <b>Verification</b>           | Run the <b>show running-config</b> command to display the configurations.                                                                                                                                                                                              |

## 5.118 failure-retry-delay

Use this command to configure the interval to reconnect to the BMP server. Use the **default** form of this command to restore the default settings.

**failure-retry-delay** *seconds*

**no failure-retry-delay**

**default failure-retry-delay**

| Parameter          | Parameter      | Description                                                                 |
|--------------------|----------------|-----------------------------------------------------------------------------|
| <b>Description</b> | <i>seconds</i> | Interval to reconnect to the BMP server, in the range of 30 to 720 seconds. |

|                               |                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | No interval is configured by default.                                                                       |
| <b>Command Mode</b>           | BMP configuration mode.                                                                                     |
| <b>Default Level</b>          | 14                                                                                                          |
| <b>Usage Guide</b>            |                                                                                                             |
| <b>Configuration Examples</b> | <p>The following example configures the interval as 60 seconds.</p> <pre>Ruijie(config)# bmp server 1</pre> |

```
Ruijie(config-bmpsrvr)# failure-retry-delay 60
```

**Verification** Run the **show running-config** command to display the configurations.

## 5.119 import map(EVPN VNI)

Use this command to configure the route map for importing the remote EVPN routes to the local VNI instance. Use the **no** form of this command to delete the route map for importing the remote EVPN routes to the local VNI instance. Use the **default** form of this command to restore the default settings.

**import map** *routemap-name*

**no import map**

**default import map**

| Parameter   | Parameter            | Description           |
|-------------|----------------------|-----------------------|
| Description | <i>routemap-name</i> | Name of the route map |

**Defaults** No route map is configured for importing the remote EVPN routes to the local VNI instance by default.

**Command Mode** EVPN VNI configuration mode.

**Default Level** 14

**Usage Guide** This command is used to filter the remote EVPN routes to be imported to the local VNI instance, or modify the attribute of the remote EVPN routes imported to the local VNI instance.

This command supports only one route map, and the old configuration is overwritten by the new configuration.

**Configuration Examples** The following example configures the route map map1 for importing the remote EVPN routes to the local VNI instance vni 1.

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 1
Ruijie(config-evpn-vni)# import map map1
```

**Verification** Run the **show running-config** command to display the configurations.

## 5.120 import path selection

Use this command to configure the route import policy. Use the **no** form of this command to delete the route import policy. Use the **default** form of this command to restore the default settings.

**import path selection** { **all** | **bestpath** | **multipath** }

**no import path selection**

**default import path selection**

| Parameter Description         | Parameter                                                                                                                                                                                   | Description                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
|                               | <b>all</b>                                                                                                                                                                                  | Imports all routes with next hops.                                                                      |
|                               | <b>bestpath</b>                                                                                                                                                                             | Imports routes with preferred next hops. By default, only routes with preferred next hops are imported. |
|                               | <b>multipath</b>                                                                                                                                                                            | Imports routes with preferred and equivalent next hops.                                                 |
| <b>Defaults</b>               | Only routes with preferred next hops are imported by default.                                                                                                                               |                                                                                                         |
| <b>Command Mode</b>           | BGP configuration mode, BGP IPv4 Unicast/VRF address family configuration mode, BGP IPv6 Unicast/VRF address family configuration mode, or BGP Scope configuration mode                     |                                                                                                         |
| <b>Default Level</b>          | 14                                                                                                                                                                                          |                                                                                                         |
| <b>Usage Guide</b>            | This command can be used to control inter-VRF route import, L3VPN remote routes import to VRF, and EVPN routes import to the IP route table.                                                |                                                                                                         |
| <b>Configuration Examples</b> | <p>The following example imports routes with all next hops to the global IPv4 route table.</p> <pre>Ruijie(config)# router bgp 65530 Ruijie(config-router)# import path selection all</pre> |                                                                                                         |
| <b>Verification</b>           | Run the <b>show running-config</b> command to display the BGP configurations.                                                                                                               |                                                                                                         |

## 5.121 maximum-paths

Use this command to configure the number of equivalent paths of the EBGp/IBGP multipath load balancing function. Use the **no** form of this command to disable the EBGp/IBGP multipath load balancing function. Use the **default** form of this command to restore the default settings.

**maximum-paths** { **ebgp** | **ibgp** } *number*

**no maximum-paths** { **ebgp** | **ibgp** }

**default maximum-paths** { **ebgp** | **ibgp** }

| Parameter Description | Parameter     | Description                                                                                                                                                                                                  |
|-----------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>ebgp</b>   | Specifies the number of equivalent paths of the EBGp multipath load balancing function.                                                                                                                      |
|                       | <b>ibgp</b>   | Specifies the number of equivalent paths of the IBGP multipath load balancing function.                                                                                                                      |
|                       | <i>number</i> | Indicates the maximum number of equivalent paths. The minimum value is 1, and the maximum value depends on the device capability. If the value is 1, the EBGp multipath load balancing function is disabled. |

**Defaults** Equivalence of multiple BGP paths is not supported by default.

**Command Mode** BGP configuration mode, BGP IPv4 Unicast address family configuration mode, BGP IPv6 Unicast address family configuration mode, BGP Scope configuration mode

**Default Level** 14

**Usage Guide** The **maximum-paths ebgp** command is also used to configure equivalence of confederation EBGp multiple paths and local inter-VRF import routes.

 IBGP and EBGp routes cannot form equivalent routes.

**Configuration Examples** The following example configures EBGp load balancing and sets the maximum number of equivalent routes to 2.

```
Ruijie(config)# router bgp 65530
Ruijie(config-router)# maximum-paths ebgp 2
```

**Verification** Run the **show running-config** command to display the BGP configurations.

## 5.122 maximum-prefix

Use this command to limit the maximum number of prefixes in the routing database in the address family. Use the **no** form of this command to restore the default setting.

**maximum-prefix** *maximum*

**no maximum-prefix**

**Parameter Description**

| Parameter      | Description                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------|
| <i>maximum</i> | The maximum number of prefixes in the routing database in the address family, in the range from 1 to 4294967295 |

**Defaults** The default maximum numbers of prefixes in the routing database are not limited.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage Guide** In a BGP address family, routing prefixes may be introduced through redistribution or learnt from neighbors, or other VRFs. Once routing prefixes in the BGP address family reaches the maximum number, this address family will enter to the overflow state.

Use the **show bgp { addressfamily | all } summary** command to display the state of routing database.

It is necessary to reconfigure BGP for state clearing, or use the **clear bgp { addressfamily | all } \*** command to reset the address family.

 When the address family is overflow as the number of prefixes reaches the maximum number, you can adjust maximum-prefix.

IPv4 unicast routes can receive the routing prefix in the following conditions even in the Overflow state:

The route information of the same routing prefix exists in the address database.

One route that overwrites this prefix (except for the default route) exists in the address database and the next-hop of this route is different from that of the newly received routing prefix.

The following example sets the maximum number of prefixes in the BGP routing database in the ipv4 multicast address family.

#### Configuration Examples

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# address-family ipv4 multicast
Ruijie(config-router-af)# maximum-prefix 65535
```

#### Related Commands

| <b>clear bgp vpngv4 unicast</b>      | Resets BGP's vpngv4 unicast address families.              |
| <b>show bgp all summary</b>          | Displays summary of BGP's all address families.            |
| <b>show bgp ipv4 mdt summary</b>     | Displays summary of BGP's ipv4 mdt address families.       |
| <b>show bgp ipv4 unicast summary</b> | Displays summary of BGP's ipv4 unicast address families.   |
| <b>show bgp ipv6 unicast summary</b> | Displays summary of BGP's ipv6 unicast address families.   |
| <b>show bgp vpngv4 summary</b>       | Displays summary of BGP's vpngv4 unicast address families. |

#### Platform

Description N/A

## 5.123 neighbor activate

Use this command to activate the neighbor or peer group in the current address mode. Use the **no** form of this command to disable this function.

**neighbor {neighbor-address | peer-group-name} activate{ ipv4 | ipv6 }**

**no neighbor {neighbor-address | peer-group-name} activate{ ipv4 | ipv6 }**

#### Parameter

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                    |                         |                                                      |
|--------------------|-------------------------|------------------------------------------------------|
| <b>Description</b> | <i>neighbor-address</i> | IP address of the peer, IPv4 address or IPv6 address |
|                    | <i>peer-group-name</i>  | Name of the peer group of up to 32 characters        |
|                    | <b>ipv4</b>             | Activate only IPv4 neighbors in the peer group       |
|                    | <b>ipv6</b>             | Activate only IPv6 neighbors in the peer group       |

**Defaults** This function is enabled in IPv4 unicast address family mode by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage Guide** The function is enabled by default for IPv4 address families. You need to set this command in other address-family configuration modes for exchanging routes.

**Configuration Examples** The following example activates the neighbor or peer group in the current address mode.

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 100
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 10.0.0.1 activate
```

| <b>Related Commands</b> | Command                   | Description               |
|-------------------------|---------------------------|---------------------------|
|                         | <b>router bgp</b>         | Enables the BGP protocol. |
|                         | <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform Description** None

## 5.124 neighbor additional-paths

Use this command to enable add-path capability on the specified peer. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *peer-address* | *peer-group-name* } **additional-paths** { **send** [**receive**] | **receive** }

**no neighbor** { *peer-address* | *peer-group-name* } **additional-paths** { **send** [**receive**] | **receive** }

**default neighbor** { *peer-address* | *peer-group-name* } **additional-paths** { **send** [**receive**] | **receive** }

| <b>Parameter Description</b> | Parameter              | Description                                                                                                     |
|------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------|
|                              | <i>peer-address</i>    | IP address of the peer                                                                                          |
|                              | <i>peer-group-name</i> | Name of the peer group                                                                                          |
|                              | <b>send</b>            | Enable the device to send the add-path route. Only when the peer enables the receive capability, the device can |

|                |                                                                                                                                             |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|                | advertise the add-path route.                                                                                                               |
| <b>receive</b> | Enable the device to receive the add-path route. Only when the peer enables the send capability, the device can receive the add-path route. |

**Defaults** Add-path capability is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/ IPv6 unicast address family configuration mode, BGP IPv4/ IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage Guide** The command is only valid for IBGP neighbors.  
BGP neighbors will be re-established after running this command.  
Only when the local host is enabled to send the add-path route and the peer device is enabled to receive the add-path route, the local host is allowed to advertise the add-path route.  
If the BGP peer group is specified, all its members will inherit the command.

**Configuration Examples** The following example sets the add-path publish capability with the neighbor 10.0.0.1.

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.0.0.1 additional-paths send
```

## 5.125 neighbor advertise additional-paths

Use this command to advertise the add-path route to the peer. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *peer-address* | *peer-group-name* } **advertise additional-paths** { **all** | **best** *number* | **ecmp** }

**no neighbor** { *peer-address* | *peer-group-name* } **advertise additional-paths**

**default neighbor** { *peer-address* | *peer-group-name* } **advertise additional-paths**

| Parameter Description | Parameter                 | Description                                                                                                                |
|-----------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------|
|                       | <i>peer-address</i>       | IP address of the peer                                                                                                     |
|                       | <i>peer-group-name</i>    | Name of the peer group                                                                                                     |
|                       | <b>all</b>                | Select all valid routes as the add-path alternative routes in the type of "all"                                            |
|                       | <b>best</b> <i>number</i> | Select the next-best routes as the add-path alternative routes in the type of "best number". Range of <i>number</i> : 2-3. |
|                       | <b>ecmp</b>               | Select the ecmp routes as the add-path alternative routes in                                                               |

|                               | the type of “ecmp”. Additional configuration is needed to select the ecmp routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |         |             |  |  |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-------------|--|--|
| <b>Defaults</b>               | The add-path route is not allowed to be advertised by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |             |  |  |
| <b>Command Mode</b>           | BGP configuration mode, BGP IPv4/ IPv6 unicast address family configuration mode, BGP IPv4/ IPv6 VRF address family configuration mode or BGP Scope configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |         |             |  |  |
| <b>Usage Guide</b>            | <p>The command is only valid for IBGP neighbors.</p> <p>Run the <b>bgp additional-paths select</b> command to select the add-path routes of the specific type. If the type of selected add-path routes is different from that of advertised ones, then the add-path route is not advertised but only the optimal route is advertised.</p> <p>Only when the local device is enaled to send the add-path route and the peer device is enable to receive the add-path route, the local device is allowed to advertise the add-path route.</p> <p>If the BGP peer group is specified, all its members will inherit the command.</p> |         |             |  |  |
| <b>Configuration Examples</b> | <p>The following example configures the neighbor 10.0.0.1. If the requirement is met then advertise the next-best route as the add-path route.</p> <pre>Ruijie(config)# router bgp 60 Ruijie(config-router)# neighbor 10.0.0.1 advertise additional-paths best 2</pre>                                                                                                                                                                                                                                                                                                                                                          |         |             |  |  |
| <b>Related Commands</b>       | <table> <tr> <th>Command</th><th>Description</th></tr> <tr> <td></td><td></td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Command | Description |  |  |

| <b>Platform Description</b>   | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |             |  |  |

## 5.126 neighbor advertisement-interval

Use this command to set the time interval to send the BGP route update message. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **advertisement-interval** *seconds*

**no neighbor** {*neighbor-address* | *peer-group-name*} **advertisement-interval**

| <b>Parameter Description</b> | Parameter               | Description                                                                       |
|------------------------------|-------------------------|-----------------------------------------------------------------------------------|
|                              | <i>neighbor address</i> | IP address of the peer                                                            |
|                              | <i>peer-group-name</i>  | Name of the peer group                                                            |
|                              | <i>seconds</i>          | Time interval to send the route update message in the range from 0 to 600 seconds |

**Defaults**

IBGP connection: 15 seconds  
EBGP connection: 30 seconds

**Command** BGP configuration mode/ BGP IPv4 VRF configuration mode/BGP IPv6 VRF address family configuration mode/BGP scope configuration mode

**Mode**

**Usage** If you have specified the BGP peer group, all members of the peer group will adopt the settings of the command.

**Guide**

**Configuration** The following example sets the time interval to send the BGP route update message.

**Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 100
Ruijie(config-router)# neighbor 10.0.0.1 advertisement-interval 10
```

**Related  
Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.127 neighbor allowas-in

Use this command to allow the PE to receive messages with the same AS number as itself. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **allowas-in** *number*

**no neighbor** {*neighbor-address* | *peer-group-name*} **allowas-in**

**Parameter  
Description**

| Parameter              | Description                                                                 |
|------------------------|-----------------------------------------------------------------------------|
| <i>neighboraddress</i> | IP address of the peer                                                      |
| <i>peer-group-name</i> | Name of the peer group                                                      |
| <i>number</i>          | Number of the AS number duplication in the range from 1 to 10, 3 by default |

**Defaults** This function is disabled by default.

**Command** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Mode**

**Usage** A typical application is spoke\_hub mode. Execute this command on the PE to enable it to receive and then send the advertised address prefix. Configure two VRFs on the PE. One VRF receives the routes of all PEs and advertises them to the CE; the other VRF receives the routes advertised by the CE and advertises them to all PEs.

**Guide**

This command applies to IBGP or EBGP peers.

The following example allows the PE to receive messages with the same AS number as itself.

#### Configuration Examples

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 100
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# neighbor 10.1.1.1 allowas-in
```

#### Related Commands

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

#### Platform

Description None

## 5.128 neighbor as-loop-check

Use this command to enable outbound loop detection for a BGP neighbor. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **as-loop-check out**

**no neighbor** { *neighbor-address* | *peer-group-name* } **as-loop-check out**

**default neighbor** { *neighbor-address* | *peer-group-name* } **as-loop-check out**

#### Parameter Description

| Parameter               | Description             |
|-------------------------|-------------------------|
| <i>neighbor-address</i> | IP address of the peer. |
| <i>peer-group-name</i>  | Name of the peer group. |

#### Defaults

The function is disabled by default.

#### Command Mode

BGP configuration mode/ BGP IPv4 VRF address family configuration mode/ BGP IPv6 VRF address family configuration mode/BGP scope configuration mode

#### Usage

If you enable this function, when the **AS Path** attribute carried in a BGP route contains the local AS number, BGP filters out the BGP route.

#### Guide

If a BGP peer group is specified, this function will automatically apply to all the member of the group.

The following example creates a neighbor on BGP IPv4 VRF configuration mode, and enables outbound loop detection for the BGP neighbor.

#### Configuration Examples

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# neighbor 10.0.0.1 remote-as 100
```

```
Ruijie(config-router-af)# neighbor 10.0.0.1 as-loop-check out
```

**Platform****Description** N/A

## 5.129 neighbor as-originate-interval

Use this command to configure the interval that the device advertises local original BGP routes to the peer (group). Use the **no** or **default** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **as-origination-interval** *seconds*

**no neighbor** { *neighbor-address* | *peer-group-name* } **as-origination-interval**

**default neighbor** { *neighbor-address* | *peer-group-name* } **as-origination-interval**

**Parameter  
Description**

| Parameter              | Description                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>neighboraddress</i> | IP address of the peer.                                                                                                                         |
| <i>peer-group-name</i> | Name of the peer group                                                                                                                          |
| <i>seconds</i>         | The interval at which the device advertises local original BGP routes to the peer (group), in the range from 1 to 65535 in the unit of seconds. |

**Defaults** The default interval is 1.**Command  
Mode** BGP configuration mode/ BGP IPv4 VRF address family configuration mode/ BGP IPv6 VRF address family configuration mode/BGP scope configuration mode**Usage  
Guide** If you specify a peer group name in this command, the configuration takes effect on all members of the peer group.

The following example configures the interval at which the device advertises local original BGP routes to the peer in the BGP IPv4 VRF address family configuration mode.

**Configuration  
Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# neighbor 10.0.0.1 remote-as 100
Ruijie(config-router-af)# neighbor 10.0.0.1 as-origination-interval 10
```

## 5.130 neighbor as-override

Use this command to allow the PE to override the AS number of a site. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **as-override**

**no neighbor** {*neighbor-address* | *peer-group-name*} **as-override**

| Parameter<br>Description | Parameter              | Description            |
|--------------------------|------------------------|------------------------|
|                          | <i>neighboraddress</i> | IP address of the peer |
|                          | <i>peer-group-name</i> | Name of the peer group |

**Defaults** This function is disabled by default.

**Command Mode** BGP IPv4 VRF address family configuration mode/ BGP IPv6 VRF address family configuration mode/BGP scope configuration mode

**Usage Guide** In general, BGP will not receive the messages with the same AS number as the autonomous area. This command can override the AS number, so that BGP can receive the messages with the same AS number.

A typical application is in a VPN where two CEs have the same AS number. Usually the CEs cannot receive messages from each other. Executing this command on a PE will override the AS number of one CE it connects. As a result, the other CE can receive the peer's route messages. This command applies only to EBGp peers.

**Configuration Examples** The following example allows the PE to override the AS number of a site.

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 100
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# neighbor 10.1.1.1 as-override
```

| Related<br>Commands | Command                   | Description               |
|---------------------|---------------------------|---------------------------|
|                     | <b>router bgp</b>         | Enables the BGP protocol. |
|                     | <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.131 neighbor bmp-active

Use this command to enable the monitor of neighbor by specified BMP server. Use the **no** form of this command to disable the monitor of neighbor by specified BMP server. Use the **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **bmp-active** { **all** | **server** *server-number* [ *server-number* [ *server-number* ] ] }

**no neighbor** { *neighbor-address* | *peer-group-name* } **bmp-active** { **all** | **server** *server-number* [ *server-number* [ *server-number* ] ] }

**default neighbor** { *neighbor-address* | *peer-group-name* } **bmp-active** { **all** | **server** *server-number* [ *server-number* [ *server-number* ] ] }

#### Parameter Description

| Parameter               | Description                                                    |
|-------------------------|----------------------------------------------------------------|
| <i>neighbor-address</i> | Specifies the peer address. It may be an IPv4 or IPv6 address. |
| <i>peer-group-name</i>  | Specifies the name of the peer group                           |
| <b>all</b>              | Specifies all BMP servers.                                     |
| <i>server-number</i>    | Specifies the example number of BMP server. Range: 1-8.        |

**Defaults** Neighbor is not monitored by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode

**Default Level** 14

**Usage Guide** Neighbor is not monitored by BMP server without the corresponding configuration.

**Configuration Examples** 1: Create the neighbor in the BGP configuration mode, and specify the neighbor to be monitored by all BMP servers.

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 100
Ruijie(config-router)# neighbor 10.0.0.1 bmp-active all
```

**Verification** Run the **show running-config** command to check the BGP configuration.

**Notes**

- 1: An error occurs when the neighbor is not activated in this address family
- % Activate the neighbor for the address family first
- 1. An error occurs if the member of the peer group is configured.
- % Invalid command for a peer-group member

## 5.132 neighbor default-fast-withdraw

Use this command to allow the BGP speaker to fast withdraw the default route to the peer (group). Use the **no** or **restore** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **default-fast-withdraw**

**no neighbor** { *neighbor-address* | *peer-group-name* } **default-fast-withdraw**

**default neighbor** { *neighbor-address* | *peer-group-name* } **default-fast-withdraw**

| Parameter<br>Description | Parameter               | Description            |
|--------------------------|-------------------------|------------------------|
|                          | <i>neighbor-address</i> | IP address of the peer |
|                          | <i>peer-group-name</i>  | Name of the peer group |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode; BGP IPv4 Unicast/VRF address family configuration mode; BGP IPv6 Unicast/VRF address family configuration mode; BGP scope configuration mode

**Usage Guide** After this function is enabled, if the preferred routes and the equivalent routes function of the default route cannot take effect, the news will be informed to the neighbor first, and then other preferred routes will be selected. If you set the command for a member in the peer, this command will overwrite the settings on the peer group.

**Configuration Examples** The following example allows the BGP speaker to fast withdraw the default route to the peer (group) 10.1.1.1.

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 80
Ruijie(config-router)# neighbor 10.1.1.1 default-fast-withdraw
```

**Platform Description** N/A

## 5.133 neighbor default-originate

Use this command to allow the BGP speaker to advertise the default route to the peer (group). Use the **no** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*]

**no neighbor** { *neighbor-address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*]

| Parameter<br>Description | Parameter               | Description                                  |
|--------------------------|-------------------------|----------------------------------------------|
|                          | <i>neighbor-address</i> | IP address of the peer                       |
|                          | <i>peer-group-name</i>  | Name of the peer group                       |
|                          | <i>map-tag</i>          | Name of the route-map of up to 32 characters |

**Defaults** This function is disabled by default.

**Command** BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP

| <b>Mode</b>                   | Unicast/IPv6 VRF address family configuration mode, BGP scope configuration mode                                                                                                                                                                                                                                                                                                                 |         |             |                   |                           |                           |                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-------------|-------------------|---------------------------|---------------------------|--------------------------|
| <b>Usage Guide</b>            | <p>This command does not require the default route in the routing table, but sends a default route whose next-hop is the local address to its neighbors.</p> <p>If you have specified the BGP peer group, all members of the peer group will adopt the settings of the command. If you set the command for a member in the peer, this command will overwrite the settings on the peer group.</p> |         |             |                   |                           |                           |                          |
| <b>Configuration Examples</b> | <p>The following example allows the BGP speaker to advertise the default route to the peer (group).</p> <pre>Ruijie(config)# router bgp 60 Ruijie(config-router)# neighbor 10.1.1.1 remote-as 80 Ruijie(config-router)# neighbor 10.1.1.1 default-originate</pre>                                                                                                                                |         |             |                   |                           |                           |                          |

## 5.134 neighbor description

Use this command to set a descriptive sentence for the specified peer (group). Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **description** *text*

**no neighbor** {*neighbor-address* | *peer-group-name*} **description**

| <b>Parameter Description</b> | Parameter               | Description                                                 |
|------------------------------|-------------------------|-------------------------------------------------------------|
|                              | <i>neighbor-address</i> | IP address of the peer                                      |
|                              | <i>peer-group-name</i>  | Name of the peer group of up to 32 characters               |
|                              | <i>text</i>             | Descriptive text of the peer (group) of up to 80 characters |

|                               |                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | This function is disabled by default.                                                                                                                                                   |
| <b>Command Mode</b>           | BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP Unicast/IPv6 VRF address family configuration mode, BGP scope configuration mode                    |
| <b>Usage Guide</b>            | This command is used to add descriptive characters for the peer (group). This may help remember features and characteristics of the peer (group).                                       |
| <b>Configuration Examples</b> | <p>The following example sets a descriptive sentence for the specified peer (group).</p> <pre>Ruijie(config)# router bgp 60 Ruijie(config-router)# neighbor 10.1.1.1 remote-as 80</pre> |

```
Ruijie(config-router)# neighbor 10.1.1.1 description xyz.com
```

### Related Commands

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

### Platform

**Description**      None

## 5.135 neighbor distribute-list

Use this command to implement the routing policy based on the ACL when receiving/sending route information from/to the specified BGP peer. Use the **no** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **distribute-list** { *access-list-number* } { **in** | **out** }

**no neighbor** { *neighbor-address* | *peer-group-name* } **distribute-list** { *access-list-number* } { **in** | **out** }

### Parameter Description

| Parameter                 | Description                                          |
|---------------------------|------------------------------------------------------|
| <i>neighbor-address</i>   | IP address of the peer                               |
| <i>peer-group-name</i>    | Name of the peer group                               |
| <i>access-list-number</i> | ACL number                                           |
| <b>in</b>                 | Specifies the ACL for filtering the incoming routes. |
| <b>out</b>                | Specifies the ACL for filtering the outgoing routes. |

**Defaults**      This function is disabled by default.

**Command Mode**      BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP Unicast /IPv6 VRF address family configuration mode, BGP scope configuration mode

### Usage Guide

For in rule or out rule, this command cannot be used together with the **neighbor prefix-list** command. Only one of them can take effect.

If you have specified the BGP peer group, all members of the peer group will adopt the settings. If you set the **neighbor distribute-list** command for a member in the peer, this command will overwrite the settings on the peer group.

You can set different filtering policies in different address-family configuration modes to control routes.

### Configuration Examples

The following example implements the routing policy based on the ACL when receiving/sending route information from/to the specified BGP peer.

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 80
Ruijie(config-router)# neighbor 10.1.1.1
distribute-list bgp-filter in
```

Description None

## 5.136 neighbor ebgp-multihop

Use this command to configure the TTL of peer (groups). Use the **no** or **default** form of this command to restore the default settings.

**neighbor** {*neighbor-address* | *peer-group-name*} **ebgp-multihop** [*ttl*]

**no neighbor** {*neighbor-address* | *peer-group-name*} **ebgp-multihop** [*ttl*]

| Parameter<br>Description | Parameter               | Description                        |
|--------------------------|-------------------------|------------------------------------|
|                          | <i>neighbor-address</i> | IP address of the peer             |
|                          | <i>peer-group-name</i>  | Name of the peer group             |
|                          | <i>ttl</i>              | Maximum hops in the range 1 to 255 |

Defaults

The TTL of the peer is the default one (255 for IBGP neighbor and 1 for EBGP neighbor).  
If "ebgp-multihop" is followed by no parameter, the ttl is 255

Command  
Mode

BGP configuration mode IPv4 VRF address family configuration mode/ IPv6 VRF address family configuration mode/BGP scope configuration mode

Usage  
Guide

To prevent routing loop and dampening, non-default routes that can reach the peer must exist between EBGP peers between which the BGP connection can only be established via multiple hops.

If the BGP peer group is specified, all members of the peer group adopt the settings. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

Configuration  
Examples

The following example allows establishing BGP connection between EBGP peers that are not directly connected.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 65100
Ruijie(config-router)# neighbor 10.0.0.1 ebgp-multihop
```

Related  
Commands

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

Platform

None

## Description

## 5.137 neighbor fall-over bfd

Use this command to enable BFD correlation with BGP. Use the **no** form or **default** form of this command to disable BFD correlation with BGP.

**neighbor** { *neighbor-address* | *peer-group-name* } **fall-over bfd**

**no neighbor** { *neighbor-address* | *peer-group-name* } **fall-over bfd**

**default neighbor** { *neighbor-address* | *peer-group-name* } **fall-over bfd**

Parameter  
Description

| Parameter               | Description                       |
|-------------------------|-----------------------------------|
| <i>neighbor-address</i> | IPv4 or IPv6 address of the peer. |
| <i>peer-group-name</i>  | Name of the peer group            |

## Defaults

BFD correlation is disabled by default.

Command  
Mode

BGP configuration mode / IPv4 VRF address family configuration mode/ IPv6 VRF address family configuration mode/BGP scope configuration mode

Usage  
Guide

Before configuring BFD correlation, the BFD session parameters of the neighbor interface must be configured.

Configuration  
Examples

The following example enables BFD correlation to detect the forwarding path between local and the neighbor 172.16.0.2.

```
Ruijie(config)# router bgp 45000
Ruijie(config-router)# neighbor 172.16.0.2 remote-as 45001
Ruijie(config-router)# neighbor 172.16.0.2 fall-over bfd
```

## 5.138 neighbor filter-list

Use this command to enable route filtering when sending/receiving routing information to/from BGP peers. Use the **no** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **filter-list** *access-list-number* { **in** | **out** }

**no neighbor** { *neighbor-address* | *peer-group-name* } **filter-list** *access-list-number* { **in** | **out** }

## Parameter

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                    |                           |                                                              |
|--------------------|---------------------------|--------------------------------------------------------------|
| <b>Description</b> | <i>neighbor-address</i>   | IP address of the peer, IPv4 address or IPv6 address         |
|                    | <i>peer-group-name</i>    | Name of the peer group                                       |
|                    | <i>access-list-number</i> | ACL number                                                   |
|                    | <b>in</b>                 | Applies as-path list on the received routing information.    |
|                    | <b>out</b>                | Applies as-path list on the distributed routing information. |

**Defaults** The function is disabled by default.

**Command Mode** BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP Unicast/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP scope configuration mode

**Usage Guide** If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If the **neighbor filter-list** command is set for a member of the peer, the setting will overwrite the setting for the group.  
You can set different filter policies in different address-family configuration modes to control routes.

The following example enables route filtering when sending/receiving routing information to/from BGP peers.

**Configuration Examples**

```
Ruijie(config)# ip as-path access-list 1 deny _123_
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 65100
Ruijie(config-router)# neighbor 10.0.0.1 filter-list 1 out
```

**Description** None

## 5.139 neighbor global-nexthop-replace-local

Use this command to replace the global address with link-local address when sending IPv6 routings to the BGP IPv6 link-local peer (group). Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **global-nexthop-replace-local**

**no neighbor** { *neighbor-address* | *peer-group-name* } **global-nexthop-replace-local**

**default neighbor** { *neighbor-address* | *peer-group-name* } **global-nexthop-replace-local**

| <b>Parameter</b> | Parameter | Description |

|------------------|-----------|-------------|

|                               |                                                                                                                                                                                                                                                    |                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>Description</b>            | <i>neighbor-address</i>                                                                                                                                                                                                                            | IP address of the peer |
|                               | <i>peer-group-name</i>                                                                                                                                                                                                                             | Name of the peer group |
| <b>Defaults</b>               | The function is disabled by default.                                                                                                                                                                                                               |                        |
| <b>Command</b>                |                                                                                                                                                                                                                                                    |                        |
| <b>Mode</b>                   | BGP IPv6 Unicast/VRF address family configuration mode, BGP Scope configuration mode.                                                                                                                                                              |                        |
| <b>Usage</b>                  | When sending IPv6 routings to the BGP IPv6 link-local peer (group), two next-hop addresses are sent by default: one is global address and the other is link-local address. Run this command to replace the global address with link local address. |                        |
| <b>Guide</b>                  | Not effective on non-link-local neighbor.                                                                                                                                                                                                          |                        |
| <b>Configuration Examples</b> | The following example replaces the global address with link-local address when advertising routings to peer FE80::1.                                                                                                                               |                        |
|                               | <pre>Ruijie(config)#router bgp 65000 Ruijie(config-router)#address-family ipv6 Ruijie(config-router-af)#neighbor FE80::1%vlan101 remote-as 1 Ruijie(config-router-af)#neighbor FE80::1%vlan101 global-nexthop-replace-local</pre>                  |                        |
| <b>Related Commands</b>       | <b>Command</b>                                                                                                                                                                                                                                     | <b>Description</b>     |
| <b>Platform</b>               |                                                                                                                                                                                                                                                    |                        |
| <b>Description</b>            | None                                                                                                                                                                                                                                               |                        |

## 5.140 neighbor ha-mode

Use this command to enable the NSR function for a BGP peer. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **ha-mode nsr**

**no neighbor** { *neighbor-address* | *peer-group-name* } **ha-mode nsr**

**default neighbor** { *neighbor-address* | *peer-group-name* } **ha-mode nsr**

|                              |                         |                                                                      |
|------------------------------|-------------------------|----------------------------------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b>        | <b>Description</b>                                                   |
|                              | <i>neighbor-address</i> | IP address of the peer, IPv4 address or IPv6 address                 |
|                              | <i>peer-group-name</i>  | Name of the peer group                                               |
|                              | <b>ha-mode</b>          | Indicates the high availability mode and supports NSR function only. |
|                              | <b>nsr</b>              | Enables the NSR function.                                            |

**Defaults** By default, it is disabled.

## Command

**Mode** BGP configuration mode; BGP IPv4 VRF configuration mode; BGP IPv6 VRF configuration mode;

## Usage Guide

None-Stop-Routing (NSR) is used to ensure uninterrupted routes during protocol restart upon a switchover between the active and standby management boards. Currently, only the IPv4/IPv6 unicast address family and the L2VPN EVPN address family support the NSR function. If a neighbor activates other address families except the unicast address family, NSR switchovers cannot be performed.

## Configuration

The following example enables NSR function for the BGP peer 10.0.0.1.

## Examples

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 65100
Ruijie(config-router)# neighbor 10.0.0.1 ha-mode nsr
```

## Platform

**Description** N/A

## 5.141 neighbor local-as

Use this command to configure the local AS number for the BGP peer, which could be used as its Remote AS to connect with local router. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **local-as** *as-number* [**no-prepend** [**replace-as** [**dual-as**]]]

**no neighbor** {*neighbor-address* | *peer-group-name*} **local-as**

## Parameter Description

| Parameter               | Description                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 address or IPv6 address                                                                                                                                                                                  |
| <i>peer-group-name</i>  | Name of the peer group                                                                                                                                                                                                                |
| <i>as-number</i>        | Local AS number, in the range from 1 to 65535.<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new AS notation range is from 1 to 4294967295, represented as from 1 to 65535.65535 in dot mode. |
| <b>no-prepend</b>       | The AS-PATH of the routing information received from the peer does not depend on the Local AS. This option is disabled by default.                                                                                                    |
| <b>replace-as</b>       | The AS-PATH of the routing information sent to the peer replaces the BGP AS with the Local AS. This option is disabled by default.                                                                                                    |
| <b>dual-as</b>          | Uses BGP AS or Local AS to establish BGP connection with the device. This option is disabled by default.                                                                                                                              |

**Defaults** No Local AS is configured for the peer. If Local AS is configured, no options is configured by default. The peer could only use Local AS to establish BGP connection with local device, and adds Local AS into the AS-PATH of the received routing information, inserts Local AS to the corresponding AS-PATH before sending the routing information to the peer.

**Command Mode** BGP configuration mode, IPv6 VRF address family configuration mode, IPv4 VRF address family configuration mode, BGP scope configuration mode

**Usage Guide** Local AS could be configured on the EBGP peer only, and if the attributes of the peer change, such as EBGP converts to IBGP or union EBGP, Local AS and corresponding options will be deleted. Local AS must be different from BGP AS and this peer's Remote AS and the union ID (if federation is configured). If you have specified the BGP peer group, all members of this peer group will adopt the settings of this command. You cannot set Local AS for the specified member of the peer group separately.

**Configuration Examples** The following example configures the local AS number for the BGP peer.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 65100
Ruijie(config-router)# neighbor 10.0.0.1 local-as 23
```

|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** N/A

## 5.142 neighbor maximum-prefix

Use this command to limit the number of prefixes received from the specified BGP peer. Use the **no** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **maximum-prefix** *maximum* [ *threshold* ]  
 { [ **restart-time** *time* ] | [ **warning-only** [ **suppress** ] ] }

**no neighbor** { *neighbor-address* | *peer-group-name* } **maximum-prefix** *maximum*

**Parameter Description**

| Parameter               | Description                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address                                                                                     |
| <i>peer-group-name</i>  | Name of the peer group                                                                                                           |
| <i>maximum</i>          | Upper limit of the number of the received route entries                                                                          |
| <i>threshold</i>        | Percentage of the maximum when alarming.                                                                                         |
| <b>restart-time</b>     | The specific time for the neighbor to restore state machine automatically after prefixes exceeds the limit and the device enters |

|                     |                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------|
|                     | idle state                                                                                                  |
| <i>time</i>         | Specify the time for the neighbor to restore state machine                                                  |
| <b>warning-only</b> | Does not terminate the BGP connection when the route entries reach the upper limit but produce a log entry. |
| <b>suppress</b>     | Stop learning when the route entries reach the upper limit.                                                 |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6/L2VPN VPWS/VPLS/EVPN address family configuration mode or BGP Scope configuration mode.

**Usage Guide** The BGP connection will be torn down when the received routes exceeds the upper limit by default. To prevent tearing down the connection, set the "warning-only" to control that. To stop learning when the received routes exceed the upper limit, set the "suppress". If there are entries exceeding the upper limit, as the order of route learning may be different, the newly learned entries may also be different.

If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

**Configuration Examples** The following example limits the number of prefixes received from the specified BGP peer.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 maximum-prefix 1000
```

| Related Commands | Command                   | Description               |
|------------------|---------------------------|---------------------------|
|                  | <b>router bgp</b>         | Enables the BGP protocol. |
|                  | <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform Description** None

## 5.143 neighbor next-hop-self

Use this command to set the next-hop of the route to the local BGP speaker while specifying the routes that the BGP peer redistributes. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **next-hop-self**

**no neighbor** {*neighbor-address* | *peer-group-name*} **next-hop-self**

| Parameter Description | Parameter               | Description                                  |
|-----------------------|-------------------------|----------------------------------------------|
|                       | <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address |
|                       | <i>peer-group-name</i>  | Name of the peer group                       |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP Unicast/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP scope configuration mode

**Usage** This command is mostly used in the non-full-mesh-type network, such as the Frame Relay and X.25, where the BGP speakers within the same subnet cannot completely be accessed mutually.

**Guide** If you have specified the BGP peer group, all members of the peer group will adopt the settings of the command.

**Configuration Examples** The following example sets the next-hop of the route to the local BGP speaker.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 next-hop-self
```

## 5.144 neighbor next-hop-unchanged

Use this command to maintain the next-hop when sending routes to the peer(group). Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **next-hop-unchanged**

**no neighbor** {*neighbor-address* | *peer-group-name*} **next-hop-unchanged**

**Parameter Description**

| Parameter                 | Description                                                         |
|---------------------------|---------------------------------------------------------------------|
| <i>neighbor-address</i>   | IP address of the peer, IPv4 or IPv6 address                        |
| <i>peer-group-name</i>    | Name of the peer group                                              |
| <b>next-hop-unchanged</b> | Maintains the next-hop while sending the routes to the peer(group). |

**Defaults** The next-hop will be changed by default when routes are sent to the EBGp peer.

**Command Mode** BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP Unicast/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP scope configuration mode

**Usage** This command is used to control to maintain the next-hop route transmitting between multi-hop EBGp peer sessions. This command cannot be configured on the route reflector. And for the client

of the route reflector, if this function is enabled, the **neighbor next-hop-self** command cannot be used to change the next-hop of routes. This function is mainly applied to the cross-domain VPN. In the implementation with the Option C adopted, to reduce the complete connectivity between the PEs of the cross-domain CPN, a route reflector can be set in every autonomous domain to establish the Multihop MP-EBGP connection to implement the VPN route interaction. As the next-hop route is changed as itself while sending routes to the EBGp peer by default, PE stations of other autonomous domains will consider the final next-hop of the VPN route as the route reflector when receiving the VPN route at last, which will result in all cross-domains VPN flow going through the reflector. However, usually this is not the optimal forwarding path, and the requirement for the forwarding performance of the RR is higher. To avoid this condition, use the **neighbor next-hop-unchanged** command in the address-family VPNv4 configuration mode to maintain the next-hop of the VPNv4 route sent to the BGP peer when establishing the cross-domain Multihop MP-EBGP connection on the router reflector.

The following example maintains the next-hop when sending routes to the peer (group).

**Configuration Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 10.1.1.1 next-hop-unchanged
```

## 5.145 neighbor password

When the BGP connection with the BGP peer is established, use this command to enable TCP MD5 authentication and set the password. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **password** [**0** | **7**] *string*

**no neighbor** {*neighbor-address* | *peer-group-name*} **password**

**Parameter Description**

| Parameter               | Description                                                           |
|-------------------------|-----------------------------------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address                          |
| <i>peer-group-name</i>  | Name of the peer group                                                |
| <b>0</b>                | Displays the password with encryption.                                |
| <b>7</b>                | Displays the password without encryption.                             |
| <i>string</i>           | Password for MD5 authentication in the range from up to 80 characters |

**Defaults**

The function is disabled by default

| <b>Command</b>                | BGP configuration mod, IPv4 VRF address family configuration mode, IPv6 VRF address family configuration mode, BGP scope configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |             |                   |                          |                           |                          |

| <b>Mode</b>                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |         |             |                   |                          |                           |                          |
| <b>Usage Guide</b>            | <p>This command will enable MD5 authentication of the TCP. BGP peers must have the same password configured; otherwise, the neighbor relationship cannot be established. When this command is set, the local BGP speaker will re-establish the BGP connection with the BGP peer. If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.</p> <p>No matter in which mode, a neighbor has only one password, not one for every address family, .</p> |         |             |                   |                          |                           |                          |
| <b>Configuration Examples</b> | <p>The following example enables TCP MD5 authentication and sets the password.</p> <pre>Ruijie(config)# router bgp 65000 Ruijie(config-router)# neighbor 10.0.0.1 password Red-Giant</pre>                                                                                                                                                                                                                                                                                                                                                                                                              |         |             |                   |                          |                           |                          |

## 5.146 neighbor peer-group (creating)

Use this command to create a BGP peer group. Use the **no** form of this command to restore the default setting.

**neighbor** *peer-group-name* **peer-group**

**no neighbor** *peer-group-name* **peer-group**

| <b>Parameter</b>              | <table><tr><th>Parameter</th><th>Description</th></tr><tr><td><i>peer-group-name</i></td><td>Name of the peer group</td></tr></table>                                     | Parameter | Description | <i>peer-group-name</i> | Name of the peer group |

| <b>show ip bgp<br/>peer-group</b>                  | Displays the information of the BGP peer.                          |

## Platform

## Description

None

## 5.147 neighbor peer-group (assigning members)

Use this command to configure the specified peer as a member of the BGP peer group. Use the **no** form of this command to restore the default setting.

**neighbor** *neighbor-address* **peer-group** *peer-group-name*

**no neighbor** *neighbor-address* **peer-group** *peer-group-name*

Parameter  
Description

| Parameter               | Description                                  |
|-------------------------|----------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address |
| <i>peer-group-name</i>  | Name of the peer group                       |

## Defaults

No peer exists in the peer group.

Command  
Mode

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IP v6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

Usage  
Guide

Members of the peer group can adopt all configurations of the peer.

It is allowed to configure an individual member of the peer group to replace the universal configuration for the peer group, but such separate configuration does not contain the configuration information that may affect the output update. In other words, every member in the peer group will always adopt the following configurations of the peer group:

remote-as, update-source, local-as, reconnect-interval, times, advertisement-interval, default-originate, next-hop-self, remove-private-as, send-community, distribute-list out, filter-list out, prefix-list out, route-map out, unsuppress-map, route-reflector-client.

Do not place neighbors of different address families in the same peer group, or place IBGP and EBGP neighbors in the same peer group.

Configuration  
Examples

The following example configures the specified peer as a member of the BGP peer group.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor Red-Giant peer-group
```

```
Ruijie(config-router)# neighbor 10.0.0.1 peer-group Red-Giant
```

| Command                               | Description                               |
|---------------------------------------|-------------------------------------------|
| <b>router bgp</b>                     | Enables the BGP protocol.                 |
| <b>neighbor remote-as</b>             | Configures the BGP peer.                  |
| <b>neighbor peer-group (creating)</b> | Creates the BGP peer group.               |
| <b>show ip bgp peer-group</b>         | Displays the information of the BGP peer. |

### Platform

**Description** None

## 5.148 neighbor pic-disable

Use this command to disable the private PIC process when distributing or receiving routes to/from specified BGP peer. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **pic-disable**

**no neighbor** { *neighbor-address* | *peer-group-name* } **pic-disable**

**default neighbor** { *neighbor-address* | *peer-group-name* } **pic-disable**

### Parameter Description

| Parameter               | Description                                  |
|-------------------------|----------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address |
| <i>peer-group-name</i>  | Name of the peer group                       |

### Defaults

This function is disabled by default.

### Command Mode

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

### Usage Guide

The extended community attributes whose type is CF and sub type is E1 are used as the extended community attributes of private PIC process. Since other vendors may use the same attributes, the private PIC process should be disabled.

### Configuration Examples

The following example disable the private PIC process for peer 10.0.0.1.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 pic-disable
Ruijie(config-router)#
```

## Platform

## Description

None

## 5.149 neighbor prefix-list

Use this command to implement the routing policy based on the prefix list to receive/transmit routes from/to the BGP peer. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **prefix-list** *prefix-list-name* {**in** | **out**}

**no neighbor** {*neighbor-address* | *peer-group-name*} **prefix-list** *prefix-list-name* {**in** | **out**}

Parameter  
Description

| Parameter               | Description                                          |
|-------------------------|------------------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address         |
| <i>peer-group-name</i>  | Name of the peer group                               |
| <i>prefix-lis-name</i>  | Name of the prefix-list of up to 32 characters       |
| <b>in</b>               | Applies the prefix list to the received routes.      |
| <b>out</b>              | Applies the prefix list to the redistributed routes. |

## Defaults

This function is disabled by default.

Command  
Mode

BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP Unicast /IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP scope configuration mode

## Usage

For the "in" rule or "out" rule, this command cannot be used together with the **neighbor distribute-list** command. That is, only one of them takes effect.

## Guide

If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If the **neighbor prefix-list in** command is set for a member of the peer, the setting will overwrite the setting for the group.

You can set different filter policies in different address-family configuration modes to control routes.

Configuration  
Examples

The following example implements the routing policy based on the prefix list to receive/transmit routes from/to the BGP peer.

```
Ruijie(config)# ip prefix-list bgp-filter deny 10.0.0.1/16
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 prefix-list bgp-filter in
```

**Platform****Description** None

## 5.150 neighbor remote-as

Use this command to configure the BGP peer (group). Use the **no** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **remote-as** { *as-number* | **route-map** *map-tag* }

**no neighbor** { *neighbor-address* | *peer-group-name* } **remote-as**

**Parameter  
Description**

| Parameter                       | Description                                                                                                                                                                                                                                                       |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>neighbor-address</i>         | IP address of the peer, IPv4 or IPv6 address                                                                                                                                                                                                                      |
| <i>peer-group-name</i>          | Name of the peer group                                                                                                                                                                                                                                            |
| <i>as-number</i>                | BGP peer (group) autonomous system number in the range from 1 to 65535<br><br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new AS notation range is from 1 to 4294967295, represented as from 1 to 65535.65535 in dot mode. |
| <b>route-map</b> <i>map-tag</i> | Specifies the routing policy when connecting to the network segment neighbor.                                                                                                                                                                                     |

**Defaults** No BGP peer is configured.

**Command  
Mode**

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage  
Guide**

If you have specified the BGP peer group, all members of the peer group will inherit the settings of the command.

The command **neighbor** *neighbor-address* **remote-as** **route-map** *map-tag* is only run to configure the network segment neighbor. The specified routing policy can only allow neighbors whose routing policy matches the AS number to establish a connection. If the routing policy does not match, the neighbor cannot be established.

**Configuration  
Examples**

The following example configures the BGP peer (group).

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 80
```

**Related  
Commands**

| Command           | Description               |
|-------------------|---------------------------|
| <b>router bgp</b> | Enables the BGP protocol. |

**Platform****Description** None

## 5.151 neighbor remove-private-as

Use this command to delete the private AS number recorded in the AS path attribute in the route sent to the specified EBGp peer. Use the **no** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **remove-private-as** [ **force** [ **ignore-remote-as** ] ]  
[ **replace-as** ] **no neighbor** { *neighbor-address* | *peer-group-name* } **remove-private-as**

**Parameter  
Description**

| Parameter               | Description                                             |
|-------------------------|---------------------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address            |
| <i>peer-group-name</i>  | Name of the peer group                                  |
| <b>force</b>            | Deletes the private AS number                           |
| <b>ignore-remote-as</b> | Ignore the AS number of private neighbor                |
| <b>replace-as</b>       | Replaces the private AS number with the local AS number |

**Defaults**

This function is disabled by default.

**Command  
Mode**

BGP configuration mode, IPv4 address family configuration mode, IPv6 address family configuration mode, IPv4 VRF address family configuration mode, IPv6 VRF address family configuration mode

**Usage  
Guide**

This command takes effect only to EBGp peers.

The AS number ranges from **1** to **4294967295**, and the private AS number ranges from **64512** to **65534** and **4200000000** to **4294967294**, which is used in specific private applications. In normal cases, you can configure this command to prevent the private AS number being disclosed to a public network.

By default, the private AS number recorded in the AS path attribute of a route is not deleted in the following scenarios:

The AS path attribute contains both private and public AS numbers.

The private AS number recorded in the AS path attribute is the AS number of the EBGp peer to be sent, to prevent a loop.

By configuring **force**, you can forcibly delete the private AS number in the preceding two scenarios.

By configuring **force ignore-remote-as**, you can ignore the AS number of the neighbor when forcibly deleting the private AS number.

By configuring **replace-as**, you can replace the private AS number with the local AS number, preventing incorrect route selection due to a short AS path.

**Configuration****Examples**

The following example deletes the private AS number recorded in the AS path attribute in the route sent to the specified EBGp peer

```
Ruijie(config)# router bgp 65000
```

```
Ruijie(config-router)# neighbor 10.0.0.1 remove-private-as
```

| Related<br>Commands | Command                   | Description               |
|---------------------|---------------------------|---------------------------|
|                     | <b>router bgp</b>         | Enables the BGP protocol. |
|                     | <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform****Description** None

## 5.152 neighbor route-map

Use this command to enable route match for the received/sent routes. Use the **no** form of this command to disable this function.

**neighbor** { *neighbor-address* | *peer-group-name* } **route-map** *map-tag* {**in** | **out**}

**no neighbor** { *neighbor-address* | *peer-group-name* } **route-map** *map-tag* {**in** | **out**}

| Parameter<br>Description | Parameter               | Description                                  |
|--------------------------|-------------------------|----------------------------------------------|
|                          | <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address |
|                          | <i>peer-group-name</i>  | Name of the peer group                       |
|                          | <i>map-tag</i>          | Name of the match rule                       |
|                          | <b>in</b>               | Applies the rule to the incoming routes.     |
|                          | <b>out</b>              | Applies the rule to the outgoing routes.     |

**Defaults** N/A

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage Guide** This command can be used to filter the incoming and outgoing routes for different neighbors by using different incoming/outgoing rules, purifying and controlling routes.  
You can set different filter policies in different address-family configuration modes to control routes.

**Configuration Examples** The following example enables route match for the received/sent routes.

```
Ruijie(config-router)# neighbor 10.0.0.1 route-map map-tag in
```

| Related<br>Commands | Command                                      | Description                                            |
|---------------------|----------------------------------------------|--------------------------------------------------------|
|                     | <b>neighbor soft-reconfiguration inbound</b> | Stores the routing information sent from the BGP peer. |
|                     | <b>show ip bgp</b>                           | Displays the BGP route entry.                          |

**Platform****Description** None

## 5.153 neighbor route-reflector-client

Use this command to configure the local device as the route reflector and specifies its client. Use the **no** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **route-reflector-client**

**no neighbor** { *neighbor-address* | *peer-group-name* } **route-reflector-client**

**default neighbor** { *neighbor-address* | *peer-group-name* } **route-reflector-client**

| Parameter   | Parameter               | Description                                             |
|-------------|-------------------------|---------------------------------------------------------|
| Description | <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address            |
|             | <i>peer-group-name</i>  | Name of the peer. The name cannot exceed 32 characters. |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage** By default, all IBGP speakers in the autonomous system must establish neighbor relationship with each other. The BGP speaker does not forward the routes learned from an IBGP peer to other IBGP peers to avoid route loop.

**Guide** This command can be used to set route reflector, so that there is no need for all IBGP speakers to establish full neighboring relationship between each other. This will allow the route reflector to forward learned IBGP routes to other IBGP peers.

**Configuration Examples** The following example configures the local device as the route reflector and specifies its client.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 route-reflector-client
```

| Related Commands | Command                                | Description                                        |
|------------------|----------------------------------------|----------------------------------------------------|
|                  | <b>router bgp</b>                      | Enables the BGP protocol.                          |
|                  | <b>neighbor remote-as</b>              | Configures the BGP peer.                           |
|                  | <b>bgp cluster-id</b>                  | Configures the cluster ID of the route reflectors. |
|                  | <b>bgp client-to-client reflection</b> | Enables the route reflection between clients       |

**Platform Description** None

## 5.154 neighbor router-mac-self

When distributing routes to the specified BGP peer, use this command to configure the router MAC attribute of EVPN routing information to the router MAC address or anycast MAC address of the local device. When distributing routes to the specified BGP peer, use the **no** form of this command to configure the router MAC attribute according to the default behavior. Use the **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **router-mac-self**

**no neighbor** { *neighbor-address* | *peer-group-name* } **router-mac-self**

**default neighbor** { *neighbor-address* | *peer-group-name* } **router-mac-self**

| Parameter              | Parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Description                                                    |

| Description            | <i>neighbor-address</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | IPv4 or IPv6 address of the peer                               |
|                        | <i>peer-group-name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Name of the peer group, containing no more than 32 characters. |
| Defaults               | This function is disabled by default. The router MAC attribute of EVPN routes is not modified during the distribution process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                |
| Command Mode           | BGP L2VPN EVPN address family configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                |
| Default Level          | 14                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                |
| Usage Guide            | <p>This command is used to modify the router MAC attribute of EVPN routes in the EVPN VXLAN scenario across data centers.</p> <div>  When the device is configured as an anycast gateway, the router MAC attribute is set to the anycast MAC address. Otherwise, the router MAC attribute is set to the router MAC address of the local device.         </div> <div>  This command takes effect only when the VNI of EVPN routes has a corresponding VNI instance on the local device.         </div> |                                                                |
| Configuration Examples | <p>The following example configures the router MAC attribute when advertising EVPN routes to the peer 10.0.0.1.</p> <pre> Ruijie(config)# router bgp 65000 Ruijie(config-router)# address-family l2vpn evpn Ruijie(config-router-af)# neighbor 10.0.0.1 router-mac-self           </pre>                                                                                                                                                                                                                                                                                                                                                                                    |                                                                |
| Verification           | Run the <b>show running-config</b> command to display the BGP configurations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                |
| Prompts                | <p>1. The following error information is displayed if the neighbor is not activated in the address family.</p> <pre>% Activate the neighbor for the address family first</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                |

2. The following error information is displayed if the neighbor is a peer group member.

```
% Invalid command for a peer-group member
```

3. The following error information is displayed if the next hop is configured to be unchanged for the peer or peer group.

```
% Cannot co-exist with next-hop-unchanged, Deconfigure first
```

## 5.155 neighbor send-community

Use this command to transmit community attributes to the specified BGP neighbor. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **send-community** [**both** | **standard** | **extended**]

**no neighbor** {*neighbor-address* | *peer-group-name*} **send-community** [**both** | **standard** | **extended**]

| Parameter<br>Description | Parameter               | Description                                       |
|--------------------------|-------------------------|---------------------------------------------------|
|                          | <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address      |
|                          | <i>peer-group-name</i>  | Name of the peer group                            |
|                          | <b>both</b>             | Transmits both standard and extended communities. |
|                          | <b>standard</b>         | Transmits the standard community only.            |
|                          | <b>extended</b>         | Transmits the extended community only.            |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage**

**Guide** This command transmits the community to the neighbor or neighbor group.

**Configuration Examples** The following example transmits community attributes to the specified BGP neighbor.

```
Ruijie(config-router)# neighbor 10.1.1.1 send-community both
```

| Related<br>Commands | Command                   | Description                 |
|---------------------|---------------------------|-----------------------------|
|                     | <b>router bgp</b>         | Enables the BGP protocol.   |
|                     | <b>neighbor remote-as</b> | Configures the BGP peer.    |
|                     | <b>ip community-list</b>  | Creates the community list. |

**Platform**

**Description** None

## 5.156 neighbor send-mapping-only

Use this command to send only mapping entries to a specified neighbor. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **send-mapping-only**

**no neighbor** { *neighbor-address* | *peer-group-name* } **send-mapping-only**

**default neighbor** { *neighbor-address* | *peer-group-name* } **send-mapping-only**

| Parameter<br>Description | Parameter               | Description                                   |
|--------------------------|-------------------------|-----------------------------------------------|
|                          | <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address  |
|                          | <i>peer-group-name</i>  | Name of the peer group of up to 32 characters |

**Defaults** This function is disabled by default.

**Command**

**Mode** BGP L2VPN EVPN address family configuration mode

**Usage**

**Guide** This command is used to send only mapping entries to a specified neighbor.

The following example send only mapping entries to 57.50.1.1.

**Configuration**

**Examples**

```
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 57.50.1.1 remote-as 65531
Ruijie(config-router)# address-family l2vpn evpn
Ruijie(config-router-af)# neighbor 57.50.1.1 activate
Ruijie(config-router-af)# neighbor 57.50.1.1 send-mapping-only
```

**Platform**

**Description** None

## 5.157 neighbor shutdown

Use this command to disconnect the BGP connection established with the specified BGP peer. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **shutdown**

**no neighbor** { *neighbor-address* | *peer-group-name* } **shutdown**

**default neighbor** { *neighbor-address* | *peer-group-name* } **shutdown**

Use this command to gracefully disconnect the BGP connection established with the specified BGP peer.

**neighbor** { *neighbor-address* | *peer-group-name* } **shutdown graceful** [ **community** *value* ] [ **delay** *time* ]

**Parameter  
Description**

| Parameter                     | Description                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------|
| <i>neighbor-address</i>       | IP address of the peer, IPv4 or IPv6 address                                                                  |
| <i>peer-group-name</i>        | Name of the peer group                                                                                        |
| <b>graceful</b>               | Shuts down BGP connection gracefully.                                                                         |
| <b>community</b> <i>value</i> | Indicates the community value carried in the route sent to the neighbor.                                      |
| <b>delay</b> <i>time</i>      | Indicates the delay time (in seconds) for shutting down BGP connections. The value range is from 1 to 65,535. |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage** This command is used to disconnect valid connection established with the specified peer (group), and delete all associated routing information. However, this command still keeps the configuration information of that specified peer (group).

**Guide** If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the settings will overwrite the settings for the group.

**Configuration Examples** The following example disconnects the BGP connection established with the specified BGP peer.

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.0.0.1 shutdown
```

**Related  
Commands**

| Command                    | Description                         |
|----------------------------|-------------------------------------|
| <b>router bgp</b>          | Enables the BGP protocol.           |
| <b>neighbor remote-as</b>  | Configures the BGP peer.            |
| <b>show ip bgp summary</b> | Displays the BGP connection status. |

**Platform**

**Description** None

## 5.158 neighbor soft-reconfiguration inbound

Use this command to store the routing information sent from the BGP peer. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **soft-reconfiguration inbound**

**no neighbor** { *neighbor-address* | *peer-group-name* } **soft-reconfiguration inbound**

**default neighbor** { *neighbor-address* | *peer-group-name* } **soft-reconfiguration inbound**

**Parameter  
Description**

| Parameter               | Description                                  |
|-------------------------|----------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address |
| <i>peer-group-name</i>  | Name of the peer group                       |

**Defaults**

This function is disabled by default.

**Command  
Mode**

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage  
Guide**

This command restarts the BGP session, and keeps the unchanged routing information sent from the BGP peer (group).

Executing this command will consume more memories. If both parties support the route refresh function, this command becomes unnecessary. You may run the **show ip bgp neighbors** command to judge whether the peer can support the route refresh function.

If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the settings will overwrite the settings for the group.

**Configuration  
Examples**

The following example stores the routing information sent from the BGP peer.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 soft-reconfiguration inbound
```

**Related  
Commands**

| Command                      | Description                               |
|------------------------------|-------------------------------------------|
| <b>router bgp</b>            | Enables the BGP protocol.                 |
| <b>neighbor remote-as</b>    | Configures the BGP peer.                  |
| <b>show ip bgp neighbors</b> | Displays the information of the BGP peer. |
| <b>clear ip bgp</b>          | Resets the BGP peer session.              |

**Platform**

**Description**

None

## 5.159 neighbor soo

Use this command to set the SOO value of the neighbor. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** {*neighbor-address* | *peer-group-name*} **soo** *soo-value*

**no neighbor** {*neighbor-address* | *peer-group-name*} **soo**

**default neighbor** { *neighbor-address* | *peer-group-name* } **soo**

| Parameter                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>neighbor-address</i>                              | IP address of the peer, IPv4 or IPv6 address                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>peer-group-name</i>                               | Name of the peer group                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameter Description</b><br><br><i>soo-value</i> | SOO value<br>There are two forms of soo_value:<br>(1)soo_value = as_num:nn<br>as_number:nn: as_number is the public AS number and nn is defined by yourself. The range is from 0 to 4294967295.<br>(2)soo_value = ip_addr:nn<br>ip_address:nn: IP address must be global and nn is defined by yourself. The range is from 0 to 65535.<br>(3)soo_value = as4_num:nn<br>as4_num is the public AS number (4 byte) and nn is defined by yourself, which ranges from 0 to 65535. |

**Defaults** This function is disabled by default.

#### Command

**Mode** BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope VRF configuration mode.

**Usage Guide** In CE dual-home mode, execute this command to prevent routes sent by CE to PEs from being sent back to CE.

#### Configuration Examples

The following example sets the SOO value of the neighbor.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 100
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router)# neighbor 10.0.0.1 soo 100:100
```

#### Related Commands

| Command           | Description                                            |
|-------------------|--------------------------------------------------------|
| <b>router bgp</b> | Enables the BGP protocol.                              |
| <b>timers bgp</b> | Configures the keepalive and holdtime values globally. |

#### Platform

**Description** None

## 5.160 neighbor timers

In specifying BGP peer to establish the BGP connection, use this command to set the keepalive and holdtime time values used for establishing the BGP connection. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **timers** { *keepalive holdtime* [ *minimum-holdtime* ] | **connect** *connect-retry* }

**no neighbor** { *neighbor-address* | *peer-group-name* } **timers** [ **connect** ]

**default neighbor** { *neighbor-address* | *peer-group-name* } **timers** [ **connect** ]

### Parameter Description

| Parameter               | Description                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address                                                                                           |
| <i>neighbor-prefix</i>  | IPv4 or IPv6 address segment of the peer                                                                                               |
| <i>peer-group-name</i>  | Name of the peer group                                                                                                                 |
| <i>keepalive</i>        | Time interval to send the KEEPALIVE message to the BGP peer.<br>Range: 0-65535 seconds                                                 |
| <i>holdtime</i>         | Time interval to consider the BGP peer alive<br>Range: 0-65535 seconds                                                                 |
| <i>minimum-holdtime</i> | Allows a minimum holdtime value of neighbor advertisement. It is unrestricted when the value is 0.<br>The range is 0 to 65535 seconds. |
| <i>connect-retry</i>    | The value of the connect-retry timer is 15s.                                                                                           |

### Defaults

*keepalive*: 60 seconds  
*holdtime*: 180 seconds  
*minimum-holdtime*: 0 seconds  
*connect-retry*: 15 seconds

### Command Mode

BGP configuration mode, BGP IPv4 VRF address family configuration mode, BGP IPv6 VRF address family configuration mode, BGP Scope configuration mode

### Usage Guide

A proper keepalive value must not exceed one-third of the holdtime value.  
 If the time is configured for an individual peer or a peer group, that peer or peer-group will use its time to replace the global time configuration and connect the peer.  
 If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the settings will overwrite the settings for the group.

### Configuration Examples

The following example sets the keepalive and holdtime time values used for establishing the BGP connection.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 80 240
```

The following example sets the connect-retry time values used for establishing the BGP connection.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 timers connect 100
```

### Related Commands

**Platform****Description** None

## 5.161 neighbor track

Use this command to configure association between BGP and TRACK to check the status of track instance and reduce the BGP convergence time. Use the **no** or **restore** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **track** *track-obj-number*

**no neighbor** { *neighbor-address* | *peer-group-name* } **track**

**default neighbor** { *neighbor-address* | *peer-group-name* } **track**

|                                        | Parameter               | Description                                   |
|----------------------------------------|-------------------------|-----------------------------------------------|
| <b>Parameter</b><br><b>Description</b> | <i>neighbor-address</i> | IP address of the peer                        |
|                                        | <i>peer-group-name</i>  | Name of the peer group of up to 32 characters |
|                                        | <i>track-obj-number</i> | Specifies the number of the tracked object.   |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode; BGP IPv4 VRF configuration mode; BGP IPv6 VRF configuration mode; and BGP scope configuration mode

**Usage**

**Guide** Please make sure that the corresponding TRACK session parameters have been configured.

The following example associates BGP and TRACK 1.

**Configuration Examples**

```
Ruijie(config)# router bgp 45000
Ruijie(config-router)# neighbor 172.16.0.2 remote-as 45001
Ruijie(config-router)# neighbor 172.16.0.2 track 1
```

**Platform****Description** None

## 5.162 neighbor transport connection-mode

Use this command to configure the connection establishment mode of a BGP neighbor. Use the **no** or **default** form of this command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **transport connection-mode** { **active-only** | **both** | **passive-only** }

**no neighbor** { *neighbor-address* | *peer-group-name* } **transport connection-mode**

**default neighbor** { *neighbor-address* | *peer-group-name* } **transport connection-mode**

| Parameter Description | Parameter               | Description                                                                     |
|-----------------------|-------------------------|---------------------------------------------------------------------------------|
|                       | <i>neighbor-address</i> | IPv4 or IPv6 address of the peer                                                |
|                       | <i>peer-group-name</i>  | Peer group name                                                                 |
|                       | <b>active-only</b>      | Specifies that a BGP neighbor can only actively establish connections.          |
|                       | <b>both</b>             | Specifies that a BGP neighbor can actively and passively establish connections. |
|                       | <b>passive-only</b>     | Specifies that a BGP neighbor can only passively establish connections.         |

**Defaults** A BGP neighbor can actively and passively establish connections by default.

**Command Mode** BGP configuration mode, BGP IPv4 VRF configuration mode, BGP IPv6 VRF configuration mode, and BGP Scope configuration mode

**Default Level** 14

**Usage Guide** Two devices serving as peers cannot configure **actively-only** or **passive-only** at the same time.  
A network segment neighbor can only be connected passively, and its connection mode is not controlled by this command.

**Configuration Examples** The following example configures that BGP peer 10.0.0.1 can only actively establish connections.

```
Ruijie(config)# router bgp 45000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 45001
Ruijie(config-router)# neighbor 10.0.0.1 transport connection-mode active-only
```

**Verification** Run the **show running-config** command to display the BGP configurations.

## 5.163 neighbor unsuppress-map

Use this command to selectively advertise routing information suppressed by aggregate-address command. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address* | *peer-group-name*} **unsuppress-map** *map-tag*

**no neighbor** {*neighbor-address* | *peer-group-name*} **unsuppress-map** *map-tag*

| Parameter Description | Parameter               | Description                                  |
|-----------------------|-------------------------|----------------------------------------------|
|                       | <i>neighbor-address</i> | IP address of the peer                       |
|                       | <i>peer-group-name</i>  | Name of the peer group                       |
|                       | <i>map-tag</i>          | Name of the route-map of up to 32 characters |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage Guide** This command advertises the specified suppressed routes.  
If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

**Configuration Examples** The following example selectively advertises routing information suppressed by aggregate-address command.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 unsuppress-map
unspress-route
```

**Related Commands**

| Command                   | Description                       |
|---------------------------|-----------------------------------|
| <b>router bgp</b>         | Enables the BGP protocol.         |
| <b>neighbor remote-as</b> | Configures the BGP peer.          |
| <b>aggregate-address</b>  | Configures the aggregate address. |
| <b>route-map</b>          | Configures the route-map          |

**Platform Description** None

## 5.164 neighbor update-delay

Use this command to configure the time of BGP delayed advertisement for first routes. Use the **no** or **restore** form of the command to restore the default settings.

**neighbor** { *neighbor-address* | *peer-group-name* } **update-delay** *time*

**no neighbor** { *neighbor-address* | *peer-group-name* } **update-delay**

**default neighbor** { *neighbor-address* | *peer-group-name* } **update-delay**

**Parameter Description**

| Parameter               | Description                                         |
|-------------------------|-----------------------------------------------------|
| <i>neighbor-address</i> | IP address of the peer, IPv4 or IPv6 address        |
| <i>peer-group-name</i>  | Name of the peer group                              |
| <i>time</i>             | Time of BGP delayed advertisement for first routes. |

**Defaults** The function is disabled by default.

**Command Mode** BGP configuration mode/ BGP IPv4 VRF address family configuration mode/ BGP IPv6 VRF address family configuration mode/ BGP scope configuration mode

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guide</b>            | <p>After BGP starts, BGP peers negotiate to establish the neighborhood before sending route information (update packets). An optimum route is calculated on the local end and sent to the peer end. By default, routes are advertised directly. After a neighbor receives a better route, it updates the route information to the peer. As a result, extra route advertisement occurs. <b>update-delay</b> can be configured to shorten the route information update time.</p> <p>If the BGP peer group is specified, all members of the peer group adopt the settings of this command.</p> |
| <b>Configuration Examples</b> | <p>The following example sets the delayed time to 60s.</p> <pre>Ruijie(config)# router bgp 65000 Ruijie(config-router)# neighbor 10.0.0.1 update-delay 60</pre>                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Platform</b>               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>            | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## 5.165 neighbor update-source

Use this command to configure the interface for BGP connection of the IBGP peer..

**neighbor** { *neighbor-address* | *peer-group-name* } **update-source** { *interface-type interface-number* | *address* } Use the **no** form of the command to remove the source address configuration for the BGP peer.

**no neighbor** { *neighbor-address* | *peer-group-name* } **update-source**

Use the **default** form of the command to restore the default settings.

**default neighbor** { *neighbor-address* | *peer-group-name* } **update-source**

| <b>Parameter Description</b> | Parameter                                        | Description                                                                                                                       |
|------------------------------|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
|                              | <i>neighbor-address</i>                          | IP address of the peer, IPv4 or IPv6 address                                                                                      |
|                              | <i>peer-group-name</i>                           | Name of the peer group                                                                                                            |
|                              | <i>interface-type</i><br><i>interface-number</i> | Interface name                                                                                                                    |
|                              | <i>address</i>                                   | The interface address which is used for BGP connection. The address type (IPv4 or IPv6) must be same as that of the peer address. |
|                              |                                                  |                                                                                                                                   |

|                     |                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>     | The local interface is used as the egress interface by default.                                                                              |
| <b>Command Mode</b> | BGP configuration mode/ IPv4 VRF address family configuration mode/ IPv6 VRF address family configuration mode/ BGP scope configuration mode |
| <b>Usage</b>        | You can use this command to enable the loopback interface to establish a BGP connection with the                                             |

**Guide**

peer.

The interface address specified for BGP connection must be valid in local, otherwise the BGP connection may be faulty.

All members in a BGP peer group inherit the settings of this command. Particularly, if the interface address is used, only the member whose address type is same as the interface address's can inherit the settings of this command.

If the IPv6 address of the loopback interface is used for neighbor connection, both peers need to be configured with the loopback interface. The BGP connection can be established only when the address of the egress interface on the peer is same as that of the neighbor in local.

A loopback interface address can be configured on different interfaces. You need to specify only the interface name,

The peer configured with the IPv6 address of loopback interface support only one-hop BGP neighbor connection.

**Configuration**

The following example establishes the BGP connection.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 update-source loopback 1
```

**Related  
Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform****Description**

None

## 5.166 neighbor version

Use this command to display the number of the BGP protocol version used by the specific BGP neighbor. Use the **no** form of this command to restore the default setting.

**neighbor** { *neighbor-address* | *peer-group-name* } **version** *number*

**no neighbor** { *neighbor-address* | *peer-group-name* } **version**

**Parameter  
Description**

| Parameter               | Description            |
|-------------------------|------------------------|
| <i>neighbor-address</i> | IP address of the peer |
| <i>peer-group-name</i>  | Name of the peer group |
| <i>number</i>           | Version number         |

**Defaults**

The default version number is 4.

**Command  
Mode**

BGP configuration mode/ BGP IPv4 VRF address family configuration mode/ BGP IPv6 VRF address family configuration mode/ BGP scope configuration mode

**Usage**

When the command is used, BGP will lose the version negotiation function.

**Guide****Configuration**

The following example displays the number of the BGP protocol version used by the specific BGP neighbor.

**Examples**

```
Ruijie(config-router)# neighbor 10.1.1.1 version 4
```

**Related  
Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform****Description**

None

## 5.167 neighbor weight

Use this command to set the weight for the specific neighbor. Use the **no** form of this command to restore the default setting.

**neighbor** {*neighbor-address*|*peer-group-name*} **weight** *number*

**no neighbor** {*neighbor-address*|*peer-group-name*} **weight**

**Parameter  
Description**

| Parameter               | Description                           |
|-------------------------|---------------------------------------|
| <i>neighbor-address</i> | IP address of the peer                |
| <i>peer-group-name</i>  | Name of the peer group                |
| <i>number</i>           | Weight, in the range from 0 to 65535. |

**Defaults**

No weight is configured for the specific neighbor by default. In this case, the learned route weight is 0 and the locally generated route's weight is 32768 initially.

**Command  
Mode**

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IP v6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP Scope configuration mode or BGP L2VPN VPWS/VPLS/EVPN address family configuration mode

**Usage  
Guide**

When the command is used, routes learnt from the neighbor use this value as the initial weight value. The higher the weight, the higher the priority is.

Executing the **set weight** command in the route map of the neighbor will overwrite this value.

**Configuration****Examples**

The following example sets the weight for the specific neighbor.

```
Ruijie(config-router)# neighbor 10.1.1.1 weight 73
```

**Related  
Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform****Description** None

## 5.168 network

Use this command to configure the network information to be advertised by the local BGP speaker.

Use the **no** form of this command to restore the default setting.

**network** { *network-number* [**mask** *mask*] | *prefix* } [**route-map** *map-tag*] [**backdoor**]

**no network** *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor**]

**Parameter****Description**

| Parameter             | Description                                  |
|-----------------------|----------------------------------------------|
| <i>network-number</i> | Network number                               |
| <i>mask</i>           | Subnet mask                                  |
| <i>prefix</i>         | Prefix address of the network segment        |
| <i>map-tag</i>        | Name of the route-map of up to 32 characters |
| <b>backdoor</b>       | The route is a backdoor route.               |

**Defaults**

No network information is specified by default.

**Command**

BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP Unicast

**Mode**

/IPv6 VRF address family configuration mode, BGP scope configuration mode

**Usage**

This command allows injecting the IGP route into the BGP routing table. The network information advertised can be direct route, static route and dynamic route.

**Guide**

The "route-map" can be used to modify the network information.

**Configuration**

The following example configures the network information to be advertised by the local BGP speaker.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# network 10.0.0.1 mask 255.255.0.0
```

**Related****Commands**

| Command                        | Description                          |
|--------------------------------|--------------------------------------|
| <b>router bgp</b>              | Enables the BGP protocol.            |
| <b>redistribute</b>            | Configures the route redistribution. |
| <b>Network synchronization</b> | Enables network synchronization.     |

**Platform****Description** None

## 5.169 network synchronization

Use this command to advertise the network information after the local BGP speaker is synchronized with the local device. Use the **no** form of this command to directly advertise the network information.

**network synchronization****no network synchronization**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** BGP configuration mode, BGP Unicast/IPv4 VRF address family configuration mode, BGP Unicast /IPv6 VRF address family configuration mode, BGP scope configuration mode BGP configura  
configuration m

**Usage Guide** This command is used to modify the status of the network during the process of advertisement. It is not recommended to turn off this switch lest route black hole is caused.

**Configuration Examples** The following example advertises the network information after the local BGP speaker is synchronized with the local device.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# network synchronization
```

|------------------|---------------------|-----------------------------------------|
|                  | <b>router bgp</b>   | Enables the BGP protocol.               |
|                  | <b>redistribute</b> | Configures the route redistribution.    |
|                  | <b>network(BGP)</b> | Configures the route to be distributed. |

**Platform Description** None

## 5.170 overflow memory-lack

Use this command to allow BGP to enter the OVERFLOW state when the memory is insufficient. Use the **no** form of this command to disable this function.

**overflow memory-lack****no overflow memory-lack**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** Allow the BGP to enter the OVERFLOW state when the memory is insufficient.

**Command Mode** BGP configuration mode, BGP scope configuration mode

**Usage Guide** In the BGP OVERFLOW state, the newly-learned routes are discarded, which prevents the memory from increasing.

When this function is enabled, if the BGP address family is in the OVERFLOW state, the newly-learned routes will be discarded, which may result in network loop. To prevent this, BGP generates a default route directing to the NULL interface, and the default route will always exist in the OVERFLOW state.

Use the **clear bgp {addressfamily|all} \*** command to reset the BGP and clear the OVERFLOW state in the BGP address family.

Use the **no** option to disallow the BGP to enter the OVERFLOW state when the memory is insufficient, which may lead to the continuous exhaustion of the memory resources. When the memory has been exhausted to a certain degree, BGP will break down all neighbors and delete all learned routes.

### Configuration

### Examples

The following example sets BGP not to enter the OVERFLOW configuration status when the memory is insufficient.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# no overflow memory-lack
```

### Related Commands

## 5.171 rd

Use this command to configure a RD value for the EVI instance. Use the **no** or **restore** form of this command to restore the default settings.

**rd { auto | rd\_value }**

**no rd { auto | rd\_value }**

**default rd**

### Parameter Description

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>auto</b>     | Generates the RD value automatically.                                                                                                                                                                                                                                                                                                                                                                 |
| <i>rd_value</i> | <p>Indicates value of the RD.</p> <p>There are 3 forms of rd_value:</p> <ol style="list-style-type: none"> <li>rd_value = as_num:nn<br/>The as_num indicates the public AS number (2 bytes) and nn is customized. The range is from 0 to 4,294,967,295.</li> <li>rd_value = ip_addr:nn<br/>The ip_add refers to the global IP address and nn is customized. The range is from 0 to 65,535.</li> </ol> |

|  |                                                                                                                                                                                                                                                                    |
|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | <p>3. rd_value = as4_num:nn</p> <p>The as4_num indicates the public AS number (2 bytes) and nn is customized. The range is from 0 to 65,535.</p> <p>The 4-byte AS notation range is from 1 to 4,294,967,295, represented as from 1 to 65535.65535 in dot mode.</p> |
|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Defaults** The RD value is not configured by default.

## Command

**Mode** evpn-vni configuration mode

If an EVI is configured with a RD value, the RD value cannot be revised. If you want to revise it, you can only delete the EVI first and then configure a new RD value for it. One EVI can be configured with one RD value only.

## Usage

### Guide

-  The RD format in 4-byte AS is **AS4:NN**. The **AS4** supports demical and dot mode. The range of **AS4** is from 1 to 4,294,967,295, represented as from 1 to 65535.65535 in dot mode. The range of **NN** is from 1 to 65,535.
-  For AS number in the range of 1 to 65,535, it will be saved in the format of 2-byte AS, because under this condition, the demical and dot mode AS are the same.

The following example sets RD for EVI 100. The value is 100 : 1.

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 100
Ruijie(config-evpn-vni)# rd 100:1
```

## Configuration

### Examples

The following example sets RD for EVI 200. The value is auto.

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 200
Ruijie(config-evpn-vni)# rd auto
```

## Platform

**Description** N/A

## 5.172 redistribute

Use this to redistribute routes between the other routing protocol and the BGP. Use the **no** form of this command to restore the default setting.

**redistribute** *protocol-type* [**route-map** *map-tag*] [**metric** *metric-value*]

**no redistribute** *protocol-type* [**route-map** *map-tag*] [**metric**]

| Parameter          | Parameter            | Description                                                        |
|--------------------|----------------------|--------------------------------------------------------------------|
| <b>Description</b> | <i>protocol-type</i> | Source protocol type of a redistributed route. The values include: |

|                                   |                                                                                                                                                                                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | <ul style="list-style-type: none"> <li>● connected</li> <li>● static</li> <li>● rip</li> <li>● arp-host (host route converted by ARP)</li> <li>● nd-route (route converted by ND)</li> <li>● aggregate (aggregation route)</li> </ul> |
| <b>route-map</b> <i>map-tag</i>   | Specifies the route map.<br>No route map is associated with by default.                                                                                                                                                               |
| <b>metric</b> <i>metric-value</i> | Sets the default metric of the routes to be redistributed, null by default.                                                                                                                                                           |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, IPv4 Unicast/VRF address family configuration mode, IPv6 Unicast/VRF address family configuration mode, BGP scope configuration mode

When a switch supports multiple routing protocols, the coordination between these protocols becomes an important task. The switch may run multiple routing protocols at the same time, so it should redistribute a protocol's information to another protocol. This is applicable to all IP routing protocols.

**Usage Guide**  When you configure the **no** form of this command with parameters, the corresponding parameter configuration will be removed. The no form removes redistribution without any parameters configured.

 The route metric generated by the route-map command takes precedence over the one generated by the metric option of this command. If both are unavailable, the redistributed one is used.

### Configuration Examples

The following example redistributes routes between the other routing protocol and the BGP.

```
Ruijie(config-router)# redistribute static route-map static-rmap
Ruijie(config-router)# no redistribute static
route-map static-rmap
Ruijie(config-router)# no redistribute static
```

## 5.173 redistribute ospf

Use this command to redistribute routes between OSPF and BGP. Use the **no** form of this command to restore the default setting.

**redistribute ospf** *process-id* [**route-map** *map-tag*] [**metric** *metric-value*] [**match internal external** [1|2] **nssa-external** [1|2]]

**no redistribute ospf** *process-id* [**route-map** *map-tag*] [**metric** *metric-value*] [**match internal external** [1|2] **nssa-external** [1|2]]

#### Parameter Description

| Parameter                         | Description                                                                                                                  |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>process-id</i>                 | OSPF process ID to be redistributed                                                                                          |
| <b>route-map</b> <i>map-tag</i>   | Specifies the route map.<br>No route map is associated by default.                                                           |
| <b>metric</b> <i>metric-value</i> | Sets the default metric of the routes to be redistributed, null by default.                                                  |
| <b>match</b>                      | Matches the sub type of OSPF routes.                                                                                         |
| <b>internal</b>                   | Matches the internal OSPF routes, the default configuration.                                                                 |
| <b>external</b> [1   2 ]          | Matches the external OSPF routes. You can specify the concrete type (v1 or v2) or v1 and v2 without indication.              |
| <b>nssa- external</b> [1   2 ]    | Matches the NSSA-external type of OSPF routes. You can specify the concrete type (v1 or v2) or v1 and v2 without indication. |

#### Defaults

This function is disabled by default.

#### Command Mode

BGP configuration mode, IPv4 Unicast/VRF address family configuration mode, IPv6 Unicast/VRF address family configuration mode, BGP scope configuration mode

When a switch supports multiple routing protocols, the coordination between these protocols becomes an important task. The switch may run multiple routing protocols at the same time, so it should redistribute a protocol's information to another protocol.

#### Usage Guide

 When you configure the **no** form of this command with parameters, the corresponding parameter configuration will be removed. The **no** form removes redistribution without any parameters configured.

 The filtering rule of OSPF routing: filtering the OSPF routing type according to the configured match option before filtering the route-map rule. The route metric generated by the **route-map** command takes precedence over the one generated by the metric option of this command. If both are not available, the redistributed one is used.

#### Configuration Examples

The following example redistributes routes between OSPF and BGP.

```
Ruijie(config-router)# redistribute ospf 2 route-map static-rmap
Ruijie(config-router)# no redistribute ospf 4 match external route-map
ospf-rmap
Ruijie(config-router)# no redistribute ospf 78
```

## 5.174 redistribute isis

Use this command to redistribute routes between ISIS and BGP. Use the **no** form of this command to restore the default setting.

**redistribute isis** [*isis-tag*] [**route-map** *map-tag*] [**metric** *metric-value*] [**level-1** | **level-1-2** | **level-2**]

**no redistribute isis** [*isis-tag*] [**route-map** *map-tag*] [**metric**] [**level-1** | **level-1-2** | **level-2**]

**Parameter  
Description**

| Parameter                         | Description                                                                 |
|-----------------------------------|-----------------------------------------------------------------------------|
| <i>isis-tag</i>                   | (Optional)ISIS process ID to be redistributed                               |
| <b>route-map</b> <i>map-tag</i>   | Specifies the route map.<br>No route map is associated by default.          |
| <b>metric</b> <i>metric-value</i> | Sets the default metric of the routes to be redistributed, null by default. |
| <b>level-1</b>                    | Redistributes level-1 ISIS routes.                                          |
| <b>level-1-2</b>                  | Redistributes level-1 and level-2 ISIS routes.                              |
| <b>level-2</b>                    | Redistributes level-2 ISIS routes.                                          |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, IPv4 Unicast/VRF address family configuration mode, IPv6 Unicast/VRF address family configuration mode, BGP scope configuration mode

When a switch supports multiple routing protocols, the coordination between these protocols becomes an important task. The switch may run multiple routing protocols at the same time, so it should redistribute a protocol's information to another protocol. This is applicable to all IP routing protocols.

**Usage  
Guide**

 When you configure the **no** form of this command with parameters, the corresponding parameter configuration will be removed. The **no** form removes redistribution without any parameters configured.

 The filtering rule of ISIS routing is: filtering the ISIS routing type according to the configured level option before filtering the route-map rule. The route metric generated by the route-map command takes precedence over the one generated by the metric option of this command. If both are unavailable, the redistributed one is used.

**Configuration  
Examples**

The following example redistributes routes between ISIS and BGP.

```
Ruijie(config-router)# redistribute isis route-map static-rmap
Ruijie(config-router)# no redistribute isis test route-map isis-rmap
Ruijie(config-router)# no redistribute isis
```

## 5.175 route mirroring

Use this command to enable the BGP packet mirroring function to send mirroring packets to the BMP server. Use the **no** form of this command to disable the BGP packet mirroring function. Use the **default** form of this command to restore the default settings.

**route mirroring****no route mirroring****default route mirroring**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults**      The BGP packet mirroring function is disabled by default.**Command**      BMP configuration mode  
**Mode****Default Level**    14**Usage Guide**    Mirroring BGP packets affect the BGP performance.**Configuration Examples**    The following example enables mirroring BGP packets to be sent to the BMP server.

```
Ruijie(config)#bmp server 1
Ruijie(config-bmpsrvr)#route mirroring
```

**Verification**    Run the **show running-config** command to display the BGP configurations.

## 5.176 router bgp

Use this command to enable the BGP protocol, configure the local autonomous system number and enter BGP protocol configuration mode. Use the **no** form of this command to restore the default setting.

**router bgp** *as-number* [ **instance** *instance-name* ]**no router bgp** *as-number*

| Parameter<br>Description | Parameter        | Description                            |
|--------------------------|------------------|----------------------------------------|
|                          | <i>as-number</i> | AS number in the range from 1 to 65535 |

|                      |                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new AS notation range is from 1 to 4294967295, represented as from 1 to 65535.65535 in dot mode. |
| <b>instance</b>      | The instance name is required for the non-default instance.                                                                                                                         |
| <i>instance-name</i> | Instance name of 1 to 32 characters.                                                                                                                                                |

**Defaults** This function is disabled by default.

## Command

**Mode** Global configuration mode

This command is used to start the BGP protocol.

## Usage

### Guide

RFC4839 defines a new reserved AS notation 23456, which cannot be used. The original private AS notation in the range from 64512 to 65534 is still effective, 65535 is reserved for special purposes.

RFC 5398 also defines two groups of new reserved AS notation for documents, whose ranges are from 64496 to 64511 and from 65536 to 65551.

**Configuration** The following example enables the BGP protocol.

**Examples** Ruijie(config)# router bgp 65000

| <b>Description</b> | <b>auto</b>     | Generates the RD value automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                    | <b>import</b>   | Sets the import RT value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                    | <b>export</b>   | Sets the export RT value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                    | <b>both</b>     | Sets the import and export RT value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                    | <i>rt_value</i> | <p>Indicates value of the RT.</p> <p>There are 3 forms of <i>rt_value</i>:</p> <ol style="list-style-type: none"> <li>1. <i>rt_value</i> = <i>as_num</i>:<i>nn</i><br/>The <i>as_num</i> indicates the public AS number (2 bytes) and <i>nn</i> is customized. The range is from 0 to 4,294,967,295.</li> <li>2. <i>rt_value</i> = <i>ip_addr</i>:<i>nn</i><br/>The <i>ip_addr</i> refers to the global IP address and <i>nn</i> is customized. The range is from 0 to 65,535.</li> <li>3. <i>rt_value</i> = <i>as4_num</i>:<i>nn</i><br/>The <i>as4_num</i> indicates the public AS number (2 bytes) and <i>nn</i> is customized. The range is from 0 to 65,535.<br/>The 4-byte AS notation range is from 1 to 4,294,967,295, represented as from 1 to 65535.65535 in dot mode.</li> </ol> |

**Defaults** The RT value is not configured by default.

## Command

**Mode** evpn-vni configuration mode

One EVI can be configured with multiple import and export RT values.

## Usage

### Guide

-  The format of auto RT is **AS2:NN**. The **AS2** is the AS number of 2B. If an AS number of 4B is configured, it will be split into two 2B AS number and then be put in the RT. The **nn** indicates value of **vni-id** and has a space of 4B.
-  If the AS number of BGP changes, the auto RT will be changed, too.
-  If the manually configured RT is coherent with the auto RT, both will be displayed. After the **auto** command is configured and the automatically generated RT value is 100 : 1, then if you delete value 100 : 1, only the value not the **auto** command will be deleted.

## Configuration

### Examples

The following example sets RT for EVI 100. The values are import RT 100:1, 100:4, export RT 100:2, 100:4, and both auto.

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 100
Ruijie(config-evpn-vni)# route-target import 100:1
Ruijie(config-evpn-vni)# route-target export 100:2
Ruijie(config-evpn-vni)# route-target both 100:4
Ruijie(config-evpn-vni)# route-target both auto
```

## Platform

**Description** N/A

## 5.179 scope

Use this command to enter the scope configuration mode and associate VRF with BGP. Use the **exit** command to exit the scope configuration mode. Use the **no** or **default** form of this command to remove the association between the VRF instance and BGP protocol.

**scope** { **global** | **vrf** *vrf-name* }

**exit**

**no scope** { **global** | **vrf** *vrf-name* }

**default scope** { **global** | **vrf** *vrf-name* }

### Parameter Description

| Parameter                  | Description           |
|----------------------------|-----------------------|
| <b>global</b>              | Global routing table. |
| <b>vrf</b> <i>vrf-name</i> | VRF instance name     |

### Defaults

No scope address family is defined by default.

### Command

#### Mode

BGP configuration mode.

Enter the scope configuration mode to perform the configuration.

To exit the scope configuration mode, use the **exit** command.

### Usage Guide

 In the scope configuration mode, the commands configured in the BGP configuration mode are converted to the form in the scope configuration mode. To restore the commands, execute the command **no route bgp** and configure the commands again.

### Configuration Examples

The following example enters the scope global configuration mode.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# scope global
```

## 5.180 show bgp all

Use this command to display all the address-families information of BGP route.

**show bgp** [ **instance** *as-num* ] **all** [ **community** [ *community-number* [ **exact-match** ] ] | **filter-list** *path-list-number* | **community-list** *community-name* [ **exact-match** ] | **extcommunity-list** *extcommunity-name* | **regexp** *regexp* | **quote-regexp** *regexp* | **inconsistent-as** ]

Display the route dampening parameter.

**show bgp** [ **instance** *as-num* ] **all dampening** { **flap-statistics** | **dampened-paths** | **parameters** }

Display the related information of the neighbors.

**show bgp** [ **instance** *as-num* ] **all neighbors** [ *neighbor-address* ] [ **received-routes** | **routes** | **advertised-routes** | **policy** [ **detail** ] ]

**show bgp** [ **instance** *as-num* ] **all summary**

Display the path information.

**show bgp** [ **instance** *as-num* ] **all paths**

Display the update-group information.

**show bgp** [ **instance** *as-num* ] **all update-group** [ *neighbor-address* | *update-group-index* ] [ **summary** ]

#### Parameter Description

| Parameter                                   | Description                                                                                                                                                                                                                                           |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>                             | Specify the instance                                                                                                                                                                                                                                  |
| <i>as-num</i>                               | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode.                          |
| <b>community</b> <i>community-number</i>    | Displays the routing information including the specified community value. Community-number can be in the format of AA:NN (autonomous system number / 2-byte number), or the following pre-defined value: internet, no-export, local-as, no-advertise. |
| <b>community-list</b> <i>community-name</i> | Displays the BGP routing information matching the specified community-list.                                                                                                                                                                           |
| <b>exact-match</b>                          | Routing information exactly matching the community value or community-list.                                                                                                                                                                           |
| <b>dampening dampened-paths</b>             | Displays the restrained routing information.                                                                                                                                                                                                          |

|                                                                             |                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dampening flap-statistics</b>                                            | Displays the routing dampening statistics.                                                                                                                                                                                             |
| <b>dampening parameters</b>                                                 | Displays the routing dampening parameters.                                                                                                                                                                                             |
| <b>extcommunity-list</b> <i>extcommunity-name</i>                           | Displays the routing information including the specified extcommunity value.                                                                                                                                                           |
| <b>filter-list</b> <i>path-list-number</i>                                  | Displays the routing information matching the filter-list.                                                                                                                                                                             |
| <b>inconsistent-as</b>                                                      | Displays the routing information of the inconsistent source AS.                                                                                                                                                                        |
| <b>neighbors</b> [ <i>neighbor-address</i> ]                                | Displays all the BGP neighbors' information.<br>Displays information about a specific neighbor when <i>neighbor-address</i> or <i>neighbor-prefix</i> is specified; otherwise, displays information about all BGP neighbors.           |
| <b>neighbors</b> <i>neighbor-address</i> <b>received-routes</b>             | Displays all routing information received from the specified peer (including the accepted and refused route).                                                                                                                          |
| <b>neighbors</b> <i>neighbor-address</i> <b>routes</b>                      | Displays all the accepted routing information received from the peer.                                                                                                                                                                  |
| <b>neighbors</b> <i>neighbor-address</i> <b>advertised-routes</b>           | Displays all the routing information sent to the specified peer.                                                                                                                                                                       |
| <b>neighbors</b> <i>neighbor-address</i> <b>policy</b>                      | Displays the related routing policy information of BGP neighbors. (General)                                                                                                                                                            |
| <b>neighbors</b> <i>neighbor-address</i> <b>policy detail</b>               | Displays the related routing policy information of BGP neighbors. (Detail)                                                                                                                                                             |
| <b>quote-regexp</b> <i>regexp</i>                                           | Displays the BGP routing information with the AS path attribute matching the specified regexp within the double quote marks.                                                                                                           |
| <b>regexp</b> <i>regexp</i>                                                 | Displays the BGP routing information with the AS path attribute matching the specified regexp.                                                                                                                                         |
| <b>update-group</b> [ <i>neighbor-address</i>   <i>update-group-index</i> ] | Displays update-group information.<br>If <i>neighbor-address</i> is specified, display the update-group information of specific neighbor.<br>If <i>update-group-index</i> is specified, display the specific update-group information. |

**Defaults** Please refer to the detailed description of **show bgp ipv4 unicast** command.

**Command**

**Mode** Privileged EXEC mode

**Usage**

**Guide** Please refer to the detailed description of **show bgp ipv4 unicast** command..

**Configuration**

**Examples** None

**Related**

**Description** None

## 5.181 show bgp bmp

Use this command to display information about a BMP server instance.

**show bgp bmp server** [ *server-number* [ **detail** ] / **detail** ]

Use this command to display neighbors monitored by the BMP server.

**show bgp bmp neighbor**

Use this command to display abstract information of a connection to the BMP server.

**show bgp bmp summary**

**Parameter  
Description**

| Parameter            | Description                                       |
|----------------------|---------------------------------------------------|
| <i>server-number</i> | ID of a BMP server instance                       |
| <b>detail</b>        | Displays information about a BMP server instance. |

**Command** Privileged EXEC mode

**Mode**

**Default Level** 14

**Usage Guide**

**Configuratio** The following example displays information about a BMP server instance.

**n Examples**

```
Ruijie#show bgp bmp server 1
BMP server 1
  BMP state = Idle
  up time      Never
```

```
BGP monitor neighbors: 4
route mirroring
```

The following example displays neighbors monitored by the BMP server.

```
Ruijie#show bgp bmp neighbor
```

| Neighbor | CfgSvr# | ActSvr# |
|----------|---------|---------|
| 3.3.3.1  | 1       | 1       |
| 3.3.3.2  | 1       | 1       |

| Field    | Description                                                          |
|----------|----------------------------------------------------------------------|
| Neighbor | Address of a monitored neighbor                                      |
| CfgSvr#  | Configured instance ID of the BMP server that monitors the neighbor. |
| ActSvr#  | Activated instance ID of the BMP server that monitors the neighbor.  |

The following example displays abstract information of a connection to the BMP server.

```
Ruijie#show bgp bmp summary
```

| ID | Host            | Port  | State  | Time  | NBRs |
|----|-----------------|-------|--------|-------|------|
| 1  | 123.123.123.123 | 12345 | Active | Never | 4    |

| Field | Description                                                          |
|-------|----------------------------------------------------------------------|
| ID    | Address of a monitored neighbor                                      |
| Host  | Configured instance ID of the BMP server that monitors the neighbor. |
| Port  | Monitoring port of the BMP server                                    |
| State | Status of the connection to the BMP server                           |
| Time  | Duration for connecting to or disconnecting from the BMP server      |
| NBRs  | Quantity of neighbors monitored by the BMP server                    |

## 5.182 show bgp ipv4 unicast

Use this command to display the IPv4 unicast route information of BGP.

```
show bgp [ instance as-num ] ipv4 unicast [ vrf vrf-name ] [ network [ network-mask ] ]
[ longer-prefixes ] ] ]
```

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **community** [ *community-number* ] [ exact-match ] ]

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **community-list** *community-name* [ exact-match ]

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **extcommunity-list** *extcommunity-name*

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **dampening dampened-paths**

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **dampening flap-statistics**

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **filter-list** *path-list-number*

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **inconsistent-as**

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **prefix-list** *ip-prefix-list-name*

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **quote-regexp** *regexp*

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **regexp** *regexp*

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **route-map** *map-tag*

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **neighbors** [ *neighbor-address* ] [ received-routes | routes | advertised-routes | policy [ detail ] ]

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **cidr-only**

**show bgp** [ instance *as-num* ] **ipv4 unicast** [ vrf *vrf-name* ] **labels**

**Parameter  
Description**

| Parameter                                      | Description                                                                                                                                                                                                                                           |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>                                | VRF instance name                                                                                                                                                                                                                                     |
| <b>instance</b>                                | Specify the instance                                                                                                                                                                                                                                  |
| <i>as-num</i>                                  | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode.                          |
| <i>network</i>                                 | Displays the specific routing information in the routing table                                                                                                                                                                                        |
| <i>network-mask</i>                            | Displays the routing information included in the specified network.                                                                                                                                                                                   |
| <b>longer-prefixes</b>                         | Displays the route map information.                                                                                                                                                                                                                   |
| <b>community</b><br><i>community-number</i>    | Displays the routing information including the specified community value. Community-number can be in the format of AA:NN (autonomous system number / 2-byte number), or the following pre-defined value: internet, no-export, local-as, no-advertise. |
| <b>community-list</b><br><i>community-name</i> | Displays the BGP routing information matching the specified community-list.                                                                                                                                                                           |
| <b>exact-match</b>                             | Routing information exactly matching the community value or community-list.                                                                                                                                                                           |

|                                                                      |                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>extcommunity-list</b><br><i>extcommunity-name</i>                 | Displays the routing information including the specified extcommunity value.                                                                                                                                                             |
| <b>dampening dampened-paths</b>                                      | Displays the restrained routing information.                                                                                                                                                                                             |
| <b>dampening flap-statistics</b>                                     | Displays the routing dampening statistics.                                                                                                                                                                                               |
| <b>filter-list</b> <i>path-list-number</i>                           | Displays the routing information matching the filter-list.                                                                                                                                                                               |
| <b>inconsistent-as</b>                                               | Displays the routing information of the inconsistent source AS.                                                                                                                                                                          |
| <b>prefix-list</b> <i>ip-prefix-list-name</i>                        | Displays the routing information matching the specified prefix-list.                                                                                                                                                                     |
| <b>quote-regexp</b> <i>regexp</i>                                    | Displays the BGP routing information with the AS path attribute matching the specified regexp within the double quote marks.                                                                                                             |
| <b>regexp</b> <i>regexp</i>                                          | Displays the BGP routing information with the AS path attribute matching the specified regexp.                                                                                                                                           |
| <b>route-map</b> <i>map-tag</i>                                      | Displays the routing information matching the specified route-map filtering condition.                                                                                                                                                   |
| <b>neighbors</b><br>[ <i>neighbor-address</i> ]                      | Displays the BGP IPv4 unicast neighbor information.<br>Displays information about a specific neighbor when <i>neighbor-address</i> or <i>neighbor-prefix</i> is specified; otherwise, displays information about all BGP IPv4 neighbors. |
| <b>neighbors</b> <i>neighbor-address</i><br><b>received-routes</b>   | Displays all routing information received from the specified peer (including the accepted and refused route).                                                                                                                            |
| <b>neighbors</b> <i>neighbor-address</i><br><b>routes</b>            | Displays all the routing information received from the peer and accepted.                                                                                                                                                                |
| <b>neighbors</b> <i>neighbor-address</i><br><b>advertised-routes</b> | Displays all the routing information sent to the specified peer.                                                                                                                                                                         |
| <b>neighbors</b> <i>neighbor-address</i><br><b>policy</b>            | Displays the related routing policy information of BGP neighbors. (General)                                                                                                                                                              |
| <b>neighbors</b> <i>neighbor-address</i><br><b>policy detail</b>     | Displays the related routing policy information of BGP neighbors. (Detail)                                                                                                                                                               |
| <b>cidr-only</b>                                                     | Displays the routing information without the category.                                                                                                                                                                                   |
| <b>labels</b>                                                        | Displays the BGP-learned and BGP-sent routes with the MPLS label.                                                                                                                                                                        |

Defaults N/A

#### Command

Mode Privileged EXEC mode

#### Usage

Use this command to view the IPv4 unicast route information of BGP. You can filter the information with the specified parameter to display the matching route information.

#### Configuration Examples

The following example displays the IPv4 unicast route information of BGP.

```
Ruijie# show bgp ipv4 unicast
BGP table version is 2, local router ID is 192.168.183.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               S Stale
```

```

## 5.188 show bgp ipv6 unicast

Use this command to display the IPv6 unicast routing information of BGP.

**show bgp ipv6 unicast** [ *vrf vrf-name* ] [*IPv6-Prefix*]

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **community** *community-number* [**exact-match**]

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **community-list** *community-name* [**exact-match**]

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **dampening** **dampened-paths**

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **dampening** **flap-statistics**

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **filter-list** *path-list-number*

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **inconsistent-as**

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **prefix-list** *ipv6-prefix-list-name*

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **quote-regexp** *regexp*

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **regexp** *regexp*

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **route-map** *map-tag*

**show bgp ipv6 unicast** [ *vrf vrf-name* ] **neighbors** [ *neighbor-address* ] [ **received-routes** | **routes** | **advertised-routes** | **policy** [ **detail** ] ]

### Parameter Description

| Parameter                                      | Description                                                                                                                                                                                                                                           |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>                                | VRF name                                                                                                                                                                                                                                              |
| <b>instance</b>                                | Specify the instance                                                                                                                                                                                                                                  |
| <i>as-num</i>                                  | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode.                          |
| <i>IPv6-prefix</i>                             | Displays the IPv6 routing information included in the specified network. The input format of the routing information prefix is X:X:X:X::X/<0-128>.                                                                                                    |
| <b>community</b><br><i>community-number</i>    | Displays the routing information including the specified community value. Community-number can be in the format of AA:NN (autonomous system number / 2-byte number), or the following pre-defined value: internet, no-export, local-as, no-advertise. |
| <b>community-list</b><br><i>community-name</i> | Displays the BGP routing information matching the specified community-list.                                                                                                                                                                           |
| <b>exact-match</b>                             | Routing information exactly matches the community value or community-list.                                                                                                                                                                            |

|                                                                      |                                                                                                                              |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>dampening dampened-paths</b>                                      | Displays the restrained routing information.                                                                                 |
| <b>dampening flap-statistics</b>                                     | Displays the routing dampening statistics.                                                                                   |
| <b>filter-list</b> <i>path-list-number</i>                           | Displays the routing information matching the filter-list.                                                                   |
| <b>inconsistent-as</b>                                               | Displays the routing information of the inconsistent source AS.                                                              |
| <b>prefix-list</b><br><i>ipv6-prefix-list-name</i>                   | Displays the routing information matching the specified prefix-list.                                                         |
| <b>quote-regexp</b> <i>regexp</i>                                    | Displays the BGP routing information with the AS path attribute matching the specified regexp within the double quote marks. |
| <b>regexp</b> <i>regexp</i>                                          | Displays the BGP routing information with the AS path attribute matching the specified regexp.                               |
| <b>route-map</b> <i>map-tag</i>                                      | Displays the routing information matching the specified route-map filtering condition.                                       |
| <b>neighbors</b> <i>neighbor-address</i><br><b>received-routes</b>   | Displays all routing information received from the specified peer (including accepted and refused routes).                   |
| <b>neighbors</b> <i>neighbor-address</i><br><b>routes</b>            | Displays all the routing information received from the peer and accepted.                                                    |
| <b>neighbors</b> <i>neighbor-address</i><br><b>advertised-routes</b> | Displays all the routing information sent to the specified peer.                                                             |
| <b>neighbors</b> <i>neighbor-address</i><br><b>policy</b>            | Displays the related routing policy information of BGP neighbors. (General)                                                  |
| <b>neighbors</b> <i>neighbor-address</i><br><b>policy detail</b>     | Displays the related routing policy information of BGP neighbors. (Detail)                                                   |

**Defaults** N/A

#### Command

**Mode** Privileged EXEC mode

#### Usage

#### Guide

Use this command to view the IPv6 unicast route information of BGP. You can filter the information with the specified parameter to display the matching route information. The function and use of this command is similar to the **show bgp ipv4 unicast** command, please refer to the command.

#### Configuration

**Examples** N/A

## 5.193 show bgp ipv6 unicast update-group

Use this command to display information about an update-group in the BGP IPv6 unicast address family.

**show bgp** [ **instance** *as-num* ] **ipv6 unicast** [ **vrf** *vrf-name* ] **update-group** [ *neighbor-address* | *update-group-index* ] [ **summary** ]

| Parameter Description | Parameter                 | Description                                                                                                                                                                                                                  |
|-----------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>vrf-name</i>           | Specifies a VRF instance name.                                                                                                                                                                                               |
|                       | <b>instance</b>           | Specify the instance                                                                                                                                                                                                         |
|                       | <i>as-num</i>             | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
|                       | <i>neighbor-address</i>   | Specifies a neighbor that belongs to an update-group whose information needs to be displayed.                                                                                                                                |
|                       | <i>update-group-index</i> | Specifies an update-group whose information needs to be displayed.                                                                                                                                                           |
|                       | <b>summary</b>            | Displays neighbor-related information.                                                                                                                                                                                       |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to display information about an update-group in the BGP IPv6 address family.

**Configuration Example** The following example displays information about an update-group in the BGP IPv6 unicast address family.

```
Ruijie#show bgp ipv6 update-group
BGP version 4 update-group 1(ref 2), internal, Address Family: IPv6 Unicast
  Update message formatted 2, replicated 2
  Minimum route advertisement interval is 0 seconds
  Minimum AS origination interval is 1 seconds
  Format state: Current working
                Refresh blocked
  Has 1 members:
    192:168:195::183
```

The following example displays the neighbor summary of update-group 1 in the BGP IPv6 unicast address family.

```
Ruijie # show bgp ipv6 unicast update-group 1 summary
BGP router identifier 192.168.183.1, local AS number 23
```

```

BGP table version is 2

2 BGP AS-PATH entries

1 BGP community entries

Neighbor          V    AS  MsgRcvd  MsgSent  TblVer  InQ   OutQ   Up/Down

**Prompt** N/A

**Platform** N/A  
**Description**

## 5.194 show bgp l2vpn

Use the following command to display the BGP L2VPN routing information.

**show bgp [ instance *as-num* ] l2vpn { vpls | vpws | evpn } all**

Use the following command to display the routing information of the BGP L2VPN address family of the *ve\_id:offset*.

**show bgp [ instance *as-num* ] l2vpn { vpls | vpws } all *ve\_id:offset***

Use the following command to display the routing information of the BGP L2VPN EVPN address family.

**show bgp [ instance *as-num* ] l2vpn evpn all { ethernet-ad | ethernet-segment | inclusive-multicast | ip-prefix | mac-ip } [ detail ]**

Use the following command to display the category 2 routing information of the BGP L2VPN EVPN address family.

```
show bgp [ instance as-num ] l2vpn evpn all mac-ip mac_addr [ ip_addr [ detail ] | ipv6_addr [ detail ] | detail ]
```

Use the following command to display the category 5 routing information of the BGP L2VPN EVPN address family.

```
show bgp [ instance as-num ] l2vpn evpn all ip-prefix { ip_addr [ detail ] | ipv6_addr [ detail ] | detail }
```

Use the following command to display the neighbor information of the BGP L2VPN address family.

```
show bgp [ instance as-num ] l2vpn { vpls | vpws | evpn } all neighbor [neighbor-address] [ policy [ detail ] ]
```

Use the following command to display the neighbor summary information of BGP L2VPN address family.

```
show bgp [ instance as-num ] l2vpn { vpls | vpws | evpn } all summary
```

Use the following command to display the L2VPN VPLS/VPWS information on the specified RD.

```
show bgp [ instance as-num ] l2vpn { vpls | vpws } rd vpn_rd [ ve_id:offset ]
```

Use the following command to display the L2VPN VPLS/VPWS information on the specified VFI.

```
show bgp [ instance as-num ] l2vpn { vpls | vpws } vfi vfi_name [ ve_id:offset ]
```

Use the following command to display the L2VPN information on the specified RD.

```
show bgp [ instance as-num ] l2vpn evpn rd vpn_rd [[ethernet-ad | ethernet-segment | inclusive-multicast | ip-prefix | mac-ip ] [ detail ]]
```

Use the following command to display the L2VPN information on the specified EVI.

```
show bgp [ instance as-num ] l2vpn evpn evi vni-id [ [ ethernet-ad | ethernet-segment | inclusive-multicast | ip-prefix | mac-ip ] [ detail ] ]
```

**Parameter  
Description**

| Parameter                   | Description                                                                                                                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>             | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>               | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <b>evpn</b>                 | Displays EVPN information.                                                                                                                                                                                                   |
| <b>vpls</b>                 | Displays VPLS information.                                                                                                                                                                                                   |
| <b>vpws</b>                 | Displays VPWS information.                                                                                                                                                                                                   |
| <b>all</b>                  | Displays all NLRI information that contains the VPLS instance or the VPWS instance.                                                                                                                                          |
| <i>ve_id:offset</i>         | Displays the VFI instance information of the specified <i>ve_id:offset</i>                                                                                                                                                   |
| <b>ethernet-ad [detail]</b> | Displays basic (detailed) information of the first type of BGP L2VPN EVPN routes.                                                                                                                                            |

|                                                                                                                         |                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ethernet-segment</b> [ <b>detail</b> ]                                                                               | Displays basic (detailed) information of the fourth type of BGP L2VPN EVPN routes.                                                                                                                               |
| <b>inclusive-multicast</b> [ <b>detail</b> ]                                                                            | Displays basic (detailed) information of the third type of BGP L2VPN EVPN routes.                                                                                                                                |
| <b>ip-prefix</b> [ <i>ip_addr</i> [ <b>detail</b> ]   <i>ipv6_addr</i> [ <b>detail</b> ]   <b>detail</b> ]              | Displays basic (detailed) information of routes with specific IP address or IPv6 address in the fifth type of BGP L2VPN EVPN routes.                                                                             |
| <b>mac-ip</b> [ <b>detail</b> ]                                                                                         | Displays basic (detailed) information of the second type of BGP L2VPN EVPN routes.                                                                                                                               |
| <b>mac-ip</b> <i>mac_addr</i> [ <i>ip_addr</i> [ <b>detail</b> ]   <i>ipv6_addr</i> [ <b>detail</b> ]   <b>detail</b> ] | Displays basic (detailed) information of routes with specific MAC addresses or MAC addresses+IP addresses/IPv6 addresses in the second type of BGP L2VPN EVPN routes.                                            |
| <b>neighbor</b> [ <i>neighbor-address</i> ]                                                                             | Displays the BGP L2VPN neighbor information.<br>You can specify the specific neighbor information by entering the parameter <i>neighbor-address</i> . Otherwise all BGP L2VPN neighbor information is displayed. |
| <b>neighbor</b> <i>neighbor-address</i> <b>policy</b>                                                                   | Displays the summarized routing policy information on BGP neighbor.                                                                                                                                              |
| <b>neighbor</b> <i>neighbor-address</i> <b>policy detail</b>                                                            | Displays the detailed routing policy information BGP neighbor.                                                                                                                                                   |
| <b>summary</b>                                                                                                          | Displays main BGP L2VPN information, including site ID, OFFSET, LABEL BASE and NEXT HOP.                                                                                                                         |

| <b>evi</b> <i>vni-id</i>                                                                                                | The specified evl instance.                                                                                                                                                                                      |

**Defaults** N/A

## Command

**Mode** Privileged EXEC mode

**Usage** Use the command **show bgp l2vpn vpls** to display the VPLS information of local configuration,  
**Guide** including Site ID, LABEL BASE and so on.

## Configuration

## Examples

The following example displays all L2VPN VPLS address family routing information.

```
Ruijie(config)# show bgp l2vpn vpls all
BGP table version: 4, local router ID is 172.168.201.1
Status codes: s suppressed, d damped, h history, * valid, > best, i -
internal, r RIB-failure, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

Network      Next Hop      Metric   LocPrf   Path
Route Distinguisher: 45000:100
*> 2:0       0.0.0.0              ?
```

```
*> 100:3    172.168.201.2    0        100        ?
Route Distinguisher: 45000:200
*>01:10    0.0.0.0            0        32768        ?
*>i200:11   172.168.201.2    0        100        ?
```

The following example displays all L2VPN VPWS address family routing information.

```
Ruijie(config)# show bgp l2vpn vpws all
BGP table version: 4, local router ID is 172.168.201.1
Status codes: s suppressed, d damped, h history, * valid, > best, i -
internal, r RIB-failure, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
Network      Next Hop      Metric    LocPrf      Path
Route Distinguisher: 45000:100
*> 3:0       0.0.0.0                ?
*> 300:3     172.168.201.2    0        100        ?
Route Distinguisher: 45000:200

## 5.195 show bgp l2vpn all connections

Use the following command to display connection information of the Kompella VPLS or the VPWS PW.

**show bgp [ instance *as-num* ] l2vpn { vpls | vpws } all connections [ vfi *vfi\_name* ] [ neighbor *neighbor-address* [ policy [ detail ] ] [ site-id *id* ] [ detail ]**

**Parameter  
Description**

| Parameter                                                    | Description                                                                                                                                                                                                                  |
|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>                                              | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>                                                | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <b>vpls</b>                                                  | Displays VPLS information.                                                                                                                                                                                                   |
| <b>vpws</b>                                                  | Displays VPWS information.                                                                                                                                                                                                   |
| <b>vfi</b> <i>vfi_name</i>                                   | Displays PW information of the specified VFI instance.                                                                                                                                                                       |
| <b>neighbor</b> <i>neighbor-address</i>                      | Displays information on the Kompella VFI PW connected with neighbor.                                                                                                                                                         |
| <b>neighbor</b> <i>neighbor-address</i> <b>policy</b>        | Displays summarized routing policy information on the BGP neighbor.                                                                                                                                                          |
| <b>neighbor</b> <i>neighbor-address</i> <b>policy detail</b> | Displays detailed routing policy information on the BGP neighbor.                                                                                                                                                            |
| <b>site-id</b> <i>id</i>                                     | Displays all connection information of all VFI instances of the specified site ID.                                                                                                                                           |
| <b>detail</b>                                                | Displays the detailed L2VPN connection information.                                                                                                                                                                          |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage** Use this command to display local configuration and the remote STA information on L2 VFI. If there

**Guide** is no remote STA, only local information is displayed.

The following example displays the PW connection information of the BGP L2VPN VPLS address family.

```
Ruijie# show bgp l2vpn vpls all connections
vfi: vpls1 (VPLS: vpnid 1)
  Local Site: 1
  Connect-Site  Status  Neighbor  Remote-Label  local-Label
  2              up      2.2.2.2    1024           80000
  3              up      3.3.3.3    1025           9192
  4              up      4.4.4.4    1024           8192
vfi: vpls2 (VPLS: vpnid 2)
  Local Site: 1
  Connect-Site  Status  Neighbor  Remote-Label  local-Label
  2              up      2.2.2.2    1124           80001
  3              up      3.3.3.3    1125           9193
  4              down    4.4.4.4    --             --
Ruijie# show bgp l2vpn vpws all connections
vfi: vpws1 (VPWS: vpnid 3)
  Local Site: 1
  Connect-Site  Status  Neighbor  Remote-Label  Local-Label
  5              up      2.2.2.2    1124           73728
  6              up      3.3.3.3    1125           73729
  7              up      4.4.4.4    1124           73730
```

### Configuration Examples

| Parameter    | Description                                                             |
|--------------|-------------------------------------------------------------------------|
| vfi          | Name of the VFI instance. (n) indicates the VPN ID of the VFI instance. |
| Local Site   | Local site ID.                                                          |
| Connect-Site | Remote site ID.                                                         |
| Status       | Whether the PW connection is up or down.                                |
| Neighbor     | The PW neighbor's IP address.                                           |
| Remote-Label | The PW remote tag (outbound tag).                                       |
| Local-Label  | The PW local tag (inbound tag).                                         |

The following example displays all VFI instance connection information of Site ID 1 of the L2VPN VPWS address family.

```
Ruijie# show bgp l2vpn vpws all connections site 1 detail
vfi: vpws1 (VPWS:vpnid 1)
  Local site: 1
  Label-base      offset      range
  73728            1           10
  73738            11          10
```

```

Remote site: 2 (connected)
  Neighbor address: 172.10.10.2
  Label-base      offset      range
  9000             1          10
  Incoming label: 73729, Outgoing label: 9000

Ruijie# show bgp l2vpn vpls all connections site 1 detail
vfi: vpls1 (VPLS:vpnid 1)
  Local site: 1
  Label-base      offset      range
  8192             1          10
  8292             11         10
  Remote site: 2 (connected)
    Neighbor address: 172.10.10.2
    Label-base      offset      range
    9000             1          10
    Incoming label: 8193, Outgoing label: 9000
  Remote site: 25 (unconnected)
    Neighbor address: 172.10.10.3
    Label-base      offset      range
    10000            1          10
  Incoming label: --, Outgoing label: --

```

|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>           | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>             | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <b>vpls</b>               | Displays the L2VPN VPLS address family information.                                                                                                                                                                          |
| <b>vpws</b>               | Displays the L2VPN VPWS address family information.                                                                                                                                                                          |
| <b>evpn</b>               | Displays the L2VPN EVPN address family information.                                                                                                                                                                          |
| <i>neighbor-address</i>   | Displays the update-group information of specified neighbor.                                                                                                                                                                 |
| <i>update-group-index</i> | Display the specified update-group information.                                                                                                                                                                              |
| <b>summary</b>            | Display neighbor information.                                                                                                                                                                                                |

**Defaults** N/A

### Command

**Mode** Privileged EXEC mode

### Usage

**Guide** Display the update-group information of BGP L2VPN address family.

The following example displays the update-group information of BGP L2VPN EVPN address family

### Configuration Examples

```
Ruijie#show bgp l2vpn evpn all update-group
BGP version 4 update-group 1(ref 2), internal, Address Family: L2VPN
EVPN
  Update message formatted 2, replicated 2
  Minimum route advertisement interval is 0 seconds
  Minimum AS origination interval is 1 seconds
  Format state: Current working
                Refresh blocked
  Has 1 members:
    192.168.195.183
```

The following example displays the neighbor summary of update-group 1 of BGP L2VPN EVPN address family

```
Ruijie # show bgp l2vpn evpn all update-group 1 summary
BGP router identifier 192.168.183.1, local AS number 23
```

```

BGP table version is 2
2 BGP AS-PATH entries
1 BGP community entries
Neighbor          V    AS  MsgRcvd  MsgSent  TblVer  InQ  OutQ  Up/Down
State/PfxRcd
192.168.195.79    4     24      0        0        0    0    0    never
Active
192.168.195.183  4     23     17       15        1    0    0    00:09:04

## 5.197 show bgp statistics

Use this command to display the BGP statistics information.

**show bgp** [ **instance** *as-num* ] **statistics** [ **vrf** *vrf-name* ]

**Parameter**

**Description**

| Parameter                  | Description                                                                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i> | Displays the BGP statistics information of VRF.                                                                                                                                                                              |
| <b>instance</b>            | Specify the instance                                                                                                                                                                                                         |
| <i>as-num</i>              | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |

**Defaults**

N/A

**Command****Mode** Privileged EXEC mode**Usage****Guide** Without the **vrf** parameter, the global BGP statistics information will be displayed.

The following example displays the BGP statistics information.

```
Ruijie#show bgp statistics
Local as 100, Router id 1.1.1.1
  Total neighbor 10, Established neighbor 9, Admin-Down neighbor 1
  IBGP neighbor 8, Established IBGP neighbor 8, Admin-Down IBGP neighbor
0
  EBGp neighbor 2, Established EBGp neighbor 1, Admin-Down EBGp neighbor
1
  AS-PATH entries 1, Community entries 1, Extended-Community entries 0

For address family: IPv4 Unicast
  Activated neighbor 9, Unactivated neighbor 0
  Activated IBGP neighbor 8, Unactivated IBGP neighbor 0
  Activated EBGp neighbor 1, Unactivated EBGp neighbor 0

For address family: IPv6 Unicast
  Activated neighbor 0, Unactivated neighbor 9
  Activated IBGP neighbor 0, Unactivated IBGP neighbor 0
  Activated EBGp neighbor 0, Unactivated EBGp neighbor 0
```

**Configuration Examples**

| Parameter                 | Description                                                  |
|---------------------------|--------------------------------------------------------------|
| Router id                 | ID of BGP router.                                            |
| Total neighbor            | Total number of neighbors.                                   |
| Established neighbor      | Number of UP neighbors.                                      |
| Admin-Down neighbor       | Number of admin down neighbors.                              |
| IBGP neighbor             | Number of IBGP neighbors.                                    |
| Established IBGP neighbor | Number of UP IBGP neighbors.                                 |
| Admin-Down IBGP neighbor  | Number of admin down IBGP neighbors.                         |
| EBGP neighbor             | Number of EBGp neighbors.                                    |
| AS-PATH entries           | Number of AS-PATH entries.                                   |
| Community entries         | Number of community entries.                                 |
| Extended-Community        | Number of extended community entries.                        |
| Established EBGp neighbor | Number of UP EBGp neighbors.                                 |
| Admin-Down EBGp neighbor  | Number of admin down EBGp neighbors.                         |
| Activated neighbor        | Number of activated neighbors.                               |
| Unactivated neighbor      | Number of unactivated neighbors, not including UP neighbors. |
| Activated IBGP neighbor   | Number of activated IBGP neighbors.                          |
| Unactivated IBGP neighbor | Number of unactivated IBGP neighbors, not including UP       |

|                           |                                                                   |
|---------------------------|-------------------------------------------------------------------|
|                           | neighbors.                                                        |
| Activated EBGp neighbor   | Number of activated EBGp neighbors.                               |
| Unactivated EBGp neighbor | Number of unactivated EBGp neighbors, not including UP neighbors. |

**Platform****Description** N/A

## 5.198 show evpn

Use this command to display the EVI instance.

**show evpn** [ *vni-id* [**detail**] / **detail** ]

| Parameter          | Parameter     | Description                                 |
|--------------------|---------------|---------------------------------------------|
| <b>Description</b> | <i>vni-id</i> | Indicates the ID of specified EVI instance. |

**Defaults** N/A**Command****Mode** Privileged EXEC mode**Usage**

If an ID of EVI instance is exported, display the information of the EVI. If no EVI ID is imported, display all EVIs' information.

**Guide**

The following example displays all information of EVI 100.

**Configuration****Examples**

```
Ruijie#show evpn 100 detail
EVI 100(L2 IRB), RD 1.1.1.1:100(auto)
  Import VPN route-target communities
    RT: 100:100(auto)
  Export VPN route-target communities
    RT: 100:100(auto)
  Bind VRF: 0(Default)
  EVI Layer 3 Interface: OverlayRouter 100
  All Route count: 6
    Ethernet Auto-discovery Route count: 0
    MAC/IP Advertisement Route count: 4
    Inclusive Multicast Ethernet Tag Route count: 2
    Ethernet Segment Route count: 0
    Install Route count: 3
```

| Parameter                           | Description                       |
|-------------------------------------|-----------------------------------|
| RD                                  | RD value of EVI.                  |
| Bind VRF                            | VRF bound with EVI.               |
| EVI Layer 3 Interface               | L3 interface associated with EVI. |
| Export VPN route-target communities | Value of the exported RT of EVI.  |
| Import VPN route-target communities | Value of the imported RT of EVI.  |
| Route count                         | Number of routes in EVI instance. |

The following example displays key information of EVI.

```
Ruijie#show evpn
vni      rd                      interface
100      1.1.1.1:100                OverlayRouter 100
300      1.1.1.1:300                N/A
789      1.1.1.1:789                N/A
1000     1.1.1.1:1000                OverlayRouter 1000
1122     1:100                      N/A
2000     1.1.1.1:2000                OverlayRouter 2000
3344     1.1.1.1:3344                N/A
1678889  1.1.1.1:40489                N/A
Total number: 8
```

| Parameter | Description                       |
|-----------|-----------------------------------|
| vni       | vni-id of EVI.                    |
| rd        | RD value of EVI                   |
| interface | L3 interface associated with EVI. |

## 5.199 show evpn mac

Use this command to display the mobilized or conflict MAC information

**show evpn mac {conflict | mobility} [ vni-id ]**

| Parameter   | Parameter | Description                |
|-------------|-----------|----------------------------|
| Description | conflict  | Display the conflicted MAC |
|             | mobility  | Display the mobilized MAC  |

|               |                                         |
|---------------|-----------------------------------------|
| <i>vni-id</i> | Display the ID of specific EVI instance |
|---------------|-----------------------------------------|

**Defaults** N/A

## Command

**Mode** Privileged EXEC mode

## Usage

## Guide

If the parameter has EVI ID, then display the MAC information of specific EVI; if no EVI ID is entered, display the MAC information of all EVI.

The following example checks the mobilized MAC information.

```
Ruijie#show evpn mac mobility
vni      mac                count  remain-time
10       0055.1000.0004         2      72
10       0055.1000.000a         1      66
10       0055.1000.000e         1      72
10       0055.1000.0013         1      27
10       0055.1000.0015         4      75
```

## Configuration

## Examples

| Parameter   | Description                                             |
|-------------|---------------------------------------------------------|
| vni         | VNI-ID of EVI.                                          |
| mac         | Mobilized MAC address                                   |
| count       | Mobility times                                          |
| remain-time | Remaining time of the timer for conflict. Unit: second. |

The following example checks the conflict MAC information.

```
Ruijie#show evpn mac conflict
Ruijie#show evpn mac conflict
vni      mac                seq      retry-time
10       0011.0011.e69c         6        -
```

| Parameter  | Description                             |
|------------|-----------------------------------------|
| vni        | vni-id of EVI.                          |
| mac        | Mobilized MAC address                   |
| seq        | Sequence number of conflict MAC address |
| Retry-time | Remaining time for retry. Unit: second  |

## 5.200 show ip bgp

Use this command to display the BGP IPv4 unicast address families' route information. The method of use is the same as other BGP show commands.

```
show ip bgp [ instance as-num ] [ vrf vrf-name ] [ network [ network-mask [ longer-prefixes ] ] |
cidr-only | community [ community-number [ exact-match ] ] | filter-list path-list-number |
community-list community-name [ exact-match ] | regex regex | quote-regex regex |
extcommunity-list extcommunity-name | inconsistent-as | prefix-list ip-prefix-list-name |
route-map map-tag ]
```

Display route flap's parameters.

```
show ip bgp dampening { flap-statistics | dampened-paths | parameters }
```

Display neighbors' related information.

```
show ip bgp [ instance as-num ] [ vrf vrf-name ] neighbors [ neighbor-address [ received-routes |
routes | advertised-routes [ policy [ detail ] ] ] ]
```

```
show ip bgp [ instance as-num ] [ vrf vrf-name ] summary
```

Display BGP IPv4 routing information with MPLS lable

```
show ip bgp [ instance as-num ] [ vrf vrf-name ] labels
```

Display related information of BGP IPv4 unicast update-group.

```
show ip bgp [ instance as-num ] [ vrf vrf-name ] update-group [ neighbor-address |
update-group-index ] [ summary ]
```

### Parameter Description

| Parameter                                      | Description                                                                                                                                                                                                                                                       |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>network</i>                                 | Displays specific route information in the route table.                                                                                                                                                                                                           |
| <b>instance</b>                                | Specify the instance                                                                                                                                                                                                                                              |
| <i>as-num</i>                                  | Specify the AS number of instance. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode.                                      |
| <i>vrf-name</i>                                | VRF instance name                                                                                                                                                                                                                                                 |
| <i>network-mask</i>                            | Displays route information in the specific network.                                                                                                                                                                                                               |
| <b>cidr-only</b>                               | Displays route information without specific category.                                                                                                                                                                                                             |
| <b>community</b><br><i>community-number</i>    | Displays route information containing specific community value. The <i>community-number</i> is the group number. The format is AA:NN (autonomous system number/2-byte figure), or the following pre-defined value: internet, no-export, local-as or no-advertise. |
| <b>community-list</b><br><i>community-name</i> | Displays the BGP route information of the specified community list. The <i>community-name</i> is the name of the community list.                                                                                                                                  |
| <b>dampening</b><br><b>dampened-paths</b>      | Displays dampened route information.                                                                                                                                                                                                                              |
| <b>dampening flap-statistics</b>               | Displays the route flap statistics.                                                                                                                                                                                                                               |

|                                                                                   |                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dampening parameters</b>                                                       | Displays believed route flap parameters.                                                                                                                                                                                               |
| <b>extcommunity-list</b>                                                          | Displays route information containing specific extcommunity value.                                                                                                                                                                     |
| <b>filter-list</b> <i>path-list-number</i>                                        | Displays the route information that complies with the filter list. The <i>path-list-number</i> is the marking number of the filter list.                                                                                               |
| <b>inconsistent-as</b>                                                            | Displays the route information of inconsistent source AS.                                                                                                                                                                              |
| <b>neighbors</b><br><i>neighbor-address</i>                                       | Displays the route information of BGP neighbors.<br>Displays information about a specific neighbor when <i>neighbor-address</i> is specified; otherwise, displays information about all BGP IPv4 neighbors.                            |
| <b>neighbors</b><br><i>neighbor-address</i><br><b>received-routes</b>             | Displays all routing information received from the specified peer (including accepted and refused routes).                                                                                                                             |
| <b>neighbors</b><br><i>neighbor-address</i> <b>routes</b>                         | Displays all the routing information received from the peer and accepted.                                                                                                                                                              |
| <b>neighbors</b><br><i>neighbor-address</i><br><b>advertised-routes</b>           | Displays all the routing information sent to the specified peer.                                                                                                                                                                       |
| <b>neighbors</b><br><i>neighbor-address</i> <b>policy</b>                         | Displays the related routing policy information of BGP neighbors. (General)                                                                                                                                                            |
| <b>neighbors</b><br><i>neighbor-address</i> <b>policy</b><br><b>detail</b>        | Displays the related routing policy information of BGP neighbors. (Detail)                                                                                                                                                             |
| <b>paths</b>                                                                      | Displays the route information in the route database.                                                                                                                                                                                  |
| <b>prefix-list</b>                                                                | Displays the route information that complies with the prefix list.                                                                                                                                                                     |
| <b>quote-regexp</b> <i>regexp</i>                                                 | Displays the BGP route information of regular expression in the specified double quotation mark of the AS route attribute.                                                                                                             |
| <b>regexp</b> <i>regexp</i>                                                       | Displays the BGP route information of specified regular expression of the AS route attribute.                                                                                                                                          |
| <b>route-map</b>                                                                  | Displays the route information that complies with the route map.                                                                                                                                                                       |
| <b>scan</b>                                                                       | Displays the BGP route scanning status.                                                                                                                                                                                                |
| <b>summary</b>                                                                    | Displays related information of BGP neighbors.                                                                                                                                                                                         |
| <b>labels</b>                                                                     | Displays the IPv4 label route information.                                                                                                                                                                                             |
| <b>update-group</b><br>[ <i>neighbor-address</i>  <br><i>update-group-index</i> ] | Displays update-group information.<br>If <i>neighbor-address</i> is specified, display the update-group information of specific neighbor.<br>If <i>update-group-index</i> is specified, display the specific update-group information. |

**Defaults** -

**Command** Privileged EXEC mode  
**Mode**

**Usage Guide** The **show ip bgp** command is the same as **show bgp ipv4 unicast** in terms of the function. All the

parameters in **show bgp ipv4 unicast** apply to **show ip bgp**.

**Configuration** -**Examples**

| Configuration<br>Examples | Command                      | Description                                                       |
|---------------------------|------------------------------|-------------------------------------------------------------------|
|                           | <b>show bgp ipv4 unicast</b> | Displays IPv4 unicast route information in BGP route information. |

**Platform** -**Description**

## 5.201 stats-reporting-period

Use this command to configure the interval for the BMP module to send status statistics. Use the **no** form of this command to cancel the configured interval for the BMP module to send status statistics. Use the **default** form of this command to restore the default settings.

**stats-reporting-period** *time*

**no stats-reporting-period**

**default stats-reporting-period**

| Parameter<br>Description | Parameter   | Description                                                          |
|--------------------------|-------------|----------------------------------------------------------------------|
|                          | <i>time</i> | Scanning interval, ranging from <b>30</b> to <b>65535</b> in seconds |

**Defaults** The BMP module does not send status statistics at a fixed interval by default.

**Command Mode** BMP configuration mode

**Default Level** 14

**Usage Guide** This command configures the interval for the BMP module to send status statistics. Without configuring this command, no status statistics are sent when the statistics count is 0 and status statistics are sent every time the statistics count is changed. This command can prevent a large amount of status statistics being sent when the count changes frequently.

**Configuration Examples** The following example sets the interval for the BMP module to send status statistics to 30s.

```
Ruijie(config)#bmp server 1
Ruijie(config-bmpsrvr)#stats-reporting-period 30
```

**Verification** Run the **show running-config** command to display the BGP configurations.

## 5.202 synchronization

Use this command to enable the synchronization mechanism of BGP and IGP routing information. Use the **no** form of this command to restore the default setting.

**synchronization**

**no synchronization**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, IPv4 VRF address family configuration mode, IPv6 VRF address family configuration mode

The synchronization between BGP and IGP aims to prevent the possible route black hole. In any of the two cases below, you may cancel the synchronization mechanism to ensure fast convergence of routing information.

**Usage Guide**

- There is no route information which passes through this AS (In general, this AS is an end AS).
- All devices within this AS operate BGP protocol and the full connection relationship is established among all BGP Speakers (The adjacent relationship is established between any two BGP Speakers).

**Configuration Examples**

The following example enables the synchronization mechanism of BGP and IGP routing information.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# synchronization
```

| Related Commands | Command           | Description               |
|------------------|-------------------|---------------------------|
|                  | <b>router bgp</b> | Enables the BGP protocol. |

**Platform Description** None

## 5.203 table-map

Use this command to control the route information distributed to the kernel table. Use the **no** form of this command to restore the default setting.

**table-map** *route-map-name*

**no table-map**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

| Description            | route-map-name                                                                                                                                                                                                        | Name of the route-map |             |           |                          |  |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|-------------|-----------|--------------------------|--|
| Defaults               | No table-map is configured by default,                                                                                                                                                                                |                       |             |           |                          |  |
| Command Mode           | BGP configuration mode / IPv4 VRF address family configuration mode/ IPv6 VRF address family configuration mode                                                                                                       |                       |             |           |                          |  |
| Usage Guide            | BGP uses the table-map to control the information distributed to the kernel routing table. The table-map is used to modify attributes of that route information, and it only takes effect on the IPv4 address-family. |                       |             |           |                          |  |
| Configuration Examples | <p>The following example controls the route information distributed to the kernel table.</p> <pre>Ruijie(config)# router bgp 65000 Ruijie(config-router)# table-map bgp_tm</pre>                                      |                       |             |           |                          |  |

## 5.204 timers bgp

Use this command to adjust the BGP network timer. Use the **no** form of this command to restore the default value.

**timers bgp** *keepalive holdtime* [*minimum-holdtime*]

**no timers bgp**

| <b>Parameter Description</b> | Parameter                                                                                           | Description                                                                                                                            |
|------------------------------|-----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
|                              | <i>keepalive</i>                                                                                    | Time interval to send the keepalive message to the BGP peer<br>Range: 0-65535 seconds.                                                 |
|                              | <i>holdtime</i>                                                                                     | Time interval to consider the BGP peer alive<br>Range: 0-65535 seconds.                                                                |
|                              | <i>minimum-holdtime</i>                                                                             | Allows a minimum holdtime value of neighbor advertisement. It is unrestricted when the value is 0.<br>The range is 0 to 65535 seconds. |
| <b>Defaults</b>              | <i>keepalive</i> : 60 seconds<br><i>holdtime</i> : 180 seconds<br><i>minum-holdtime</i> : 0 seconds |                                                                                                                                        |
| <b>Command Mode</b>          | BGP configuration mode                                                                              |                                                                                                                                        |

A proper keepalive value must not exceed one-third of the holdtime value.

**Usage**

If the time is configured for an individual peer or a peer group, that peer or peer-group will use its time to replace the global time configuration and connect the peer.

**Guide**

If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

**Configuration**

The following example adjusts the BGP network timer.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# timers bgp 80 240
```

None

## 5.205 update-source

Use this command to set the network interface used when a TCP connection is established to the BMP server. Use the **no** form of this command to delete the source address configuration of the BGP peer. Use the **default** form of this command to restore the default settings.

**update-source** *interface-type interface-number*

**no update-source**

**default update-source**

**Parameter Description**

| Parameter                              | Description    |
|----------------------------------------|----------------|
| <i>interface-type interface-number</i> | Interface name |

**Defaults**

The optimal local interface is used as the output interface by default.

**Command**

BMP configuration mode

**Mode****Default Level**

14

**Usage Guide**

Use this command to use a loopback interface to establish a TCP connection to the BMP server.

If the network interface address is specified when a TCP connection is established, the address must be a valid local interface address. Otherwise, the TCP connection establishment is affected.

**Configuration**

The following example sets loopback 1 as the TCP source address when a connection is established to BGP peer 10.0.0.1.

**Examples**

```
Ruijie(config)# bmp server 1
Ruijie(config-bmpsrvr)# update-source loopback 1
```

**Verification** Run the **show running-config** command to display the BMP configurations.

## 5.206 vni

Use this command to create an EVI instance. Use the **no** form of this command to delete the EVI instance. Use the **default** form of this command to restore the default settings.

**vni** *vni-id*

**no vni** *vni-id*

**default vni** *vni-id*

| Parameter   | Parameter     | Description                                      |
|-------------|---------------|--------------------------------------------------|
| Description | <i>vni-id</i> | Indicates the VNI ID. Ranges from 1 to 16777215. |

**Defaults** N/A

**Command**

**Mode** EVPN configuration mode

**Usage**

Configure the EVPN mode first, and then enter the evpn-vni configuration mode. Run exit command to exit.

**Guide**

**Configuration**

The following example configures an EVI instance in EVPN mode.

**Examples**

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 100
```

## 6 RIPng Commands

### 6.1 clear ipv6 rip

Use this command to clear the RIPng routes.

**clear ipv6 rip**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** None

**Command mode** Privileged EXEC mode

**Usage Guide** Running this command removes all RIPng routes and this operation may have great impact on the RIPng protocol. This command should be used with caution.

**Configuration** The following example clears the RIPng routes:

**Examples** Ruijie# clear ipv6 rip

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform** N/A  
**Description**

### 6.2 default-metric

Use this command to configure the default metric for RIPng. Use the **no** form of this command to restore the default value.

**default-metric** *metric*

**no default-metric**

**Parameter  
Description**

| Parameter     | Description                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <i>metric</i> | Sets the default metric value. The valid range is from 1 to 16. The route is unreachable if the metric value is larger than or equal to 16. |

**Defaults** 1

**Command mode** Routing process configuration mode.

**Usage Guide** This command shall be used with the **redistribute** command. When redistributing the route from one route process to RIPng, due to the incompatibility of metric calculation mechanisms of different routing protocols, it fails to translate the routing metric values. To this end, the RIPng metric value shall be defined when translating the metric values. If there is no defined metric value, use the **default-metric** command to define one; and the defined metric value will overwrite the value of the **default-metric** command. By default, the **default-metric** value is 1.

**Configuration Examples** The following example redistributes the static route the RIP process and set the metric value to 3:

```
Ruijie(config-router)# default-metric 3
Ruijie(config-router)# redistribute static
```

**Related Commands**

| Command             | Description                                                            |
|---------------------|------------------------------------------------------------------------|
| <b>redistribute</b> | Redistributes the route from one route domain to another route domain. |

**Platform** N/A

**Description**

## 6.3 distance

Use this command to set the administrative distance of RIPng. Use the **no** form of this command to restore the default value.

**distance** *distance*

**no distance**

**Parameter Description**

| Parameter       | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| <i>distance</i> | Sets the RIPng administrative distance. The range is from 1 to 254. |

**Defaults** 120

**Command mode** Routing process configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the RIPng administrative distance as 160:

**Examples**

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# distance 160
```

**Description**

## 6.4 distribute-list

Use this command to filter the in/out route in the prefix list. Use the **no** form of this command to remove route filtering.

**distribute-list** **prefix-list** *prefix-list-name* { **in** | **out** } [ *interface-type interface-name* ]

**no distribute-list** **prefix-list** *prefix-list-name* { **in** | **out** } [ *interface-type interface-name* ]

**Parameter  
Description**

| Parameter                                      | Description                                                        |
|------------------------------------------------|--------------------------------------------------------------------|
| <b>prefix-list</b> <i>prefix-list-name</i>     | Name of the prefix list which is used to filter the route.         |
| <b>in</b>   <b>out</b>                         | Filters the in or out route in the distribute list.                |
| <i>interface-type</i><br><i>interface-name</i> | (Optional) Applies the distribute list to the specified interface. |

**Defaults**

By default, no distribute list is defined.

**Command  
mode**

Routing process configuration mode.

**Usage Guide**

This command is used to configure the route distribution control list to filter all update routes for the purpose of refusing to receive or send the specified routes. If the interface is not specified, the update routes on all interfaces are filtered.

**Configuration**

The following example filters the received update route on the interface eth0 (only those update routes within the **prefix-list** *allowpre* prefix list range can be received)

**Examples**

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# distribute-list prefix-list allowpre in eth0
```

**Related  
Commands**

**Description**

## 6.5 graceful-restart

Use this command to configure the RIP graceful restart (GR) function for a device. Use the **no** form of this command to restore the default configuration.

**graceful-restart** [ **grace-period** *grace-period* ]

**no graceful-restart** [ **grace-period** ]

**Parameter  
Description**

| Parameter               | Description                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>graceful-restart</b> | Enables the GR function.                                                                                                                                                                      |
| <b>grace-period</b>     | (Optional) Configures the grace period.                                                                                                                                                       |
| <i>grace-period</i>     | (Optional) Indicates the user-defined GR period.<br>The default value is the smaller value between twice the update time and 60 seconds.<br>The range is from 1 to 1,800. The unit is second. |

**Defaults** This function is enabled by default.

**Command**

**Mode** Routing process configuration mode

**Usage Guide** The GR function is configured on the RIP instances. Different parameters can be configured for different RIP instances.

The GR period refers to the time from the startup to the end of RIP GR. During this period, the forwarding table remains unchanged and the RIP route is restored to the state before protocol restart. When the GR period expires, RIP exits the GR state and performs normal RIP operation.

The **graceful-restart grace-period** command enables users to modify GR period. Note: Make sure that GR is completed before the RIP route is validate and after an RIP route update cycle elapses. If an improper value is configured, non-stop data forwarding cannot be ensured during the GR process. For example, if the GR period is longer than the time when the neighbor's route is unavailable and GR is not completed before the route is validated, then the neighbor is not re-informed of the route and forwarding of the neighbor's route is terminated when it is validated, which results in data forwarding interruption. Therefore, unless otherwise specified, it is not recommended to adjust the GR period. If the period needs to be changed, determine that the grace period is longer than the route update cycle and shorter than the time when the route is unavailable in combination with the configuration of the **timers basic** command.

During the RIP GR period, the network must be stable.

**Configuration Examples** The following example enables the RIP GR function and configures the GR period parameters of the GR function.

```
Ruijie(config)# router rip
Ruijie(config-router)# graceful-restart grace-period 90
```

**Related  
Commands**

| Command             | Description            |
|---------------------|------------------------|
| <b>timers basic</b> | Configures RIP timers. |

**Platform**

N/A

**Description**

## 6.6 ipv6 rip default-information

Use this command to generate a default IPv6 route to the RIPng. Use the **no** form of this command to remove the default route.

**ipv6 rip default-information** { **only** | **originate** } [ **metric** *metric-value* ]

**no ipv6 rip default-information**

**Parameter  
Description**

| Parameter                         | Description                                                                                            |
|-----------------------------------|--------------------------------------------------------------------------------------------------------|
| <b>only</b>                       | Advertises the IPv6 default route only.                                                                |
| <b>originate</b>                  | Advertises both of the IPv6 default route and other routes.                                            |
| <b>metric</b> <i>metric-value</i> | Sets the metric value for the default route. The valid range is from 1 to 15. The default metric is 1. |

**Defaults**

By default, no default route is configured.

**Command  
mode**

Interface configuration mode

**Usage Guide**

With this command configured on an interface, the interface advertises an IPv6 default route and the route itself is not to join the device route forwarding table and the RIPng route database.

To avoid the route loop, once this command has been configured on the interface, RIPng refuses to receive the default route update message advertised from the neighbor.

**Configuration**

The following example creates a default route to the RIPng routing process on the interface ethernet0/0 and enable this interface to advertise the default route only:

**Examples**

```
Ruijie(config)# interface ethernet 0/0
Ruijie(config-if)# ipv6 rip default-information only
```

**Related  
Commands**

| Command                       | Description                                |
|-------------------------------|--------------------------------------------|
| <b>show ipv6 rip</b>          | Displays the RIPng process and statistics. |
| <b>show ipv6 rip database</b> | Displays the RIPng route.                  |

**Platform** N/A

**Description**

## 6.7 ipv6 rip enable

Use this command to enable the RIPng on the interface. Use the **no** form of this command to disable RIPng on the interface.

**ipv6 rip enable**

**no ipv6 rip enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command mode** Interface configuration mode.

**Usage Guide** This command is used to add the RIPng interface. Before this command is configured, if the RIPng is not enabled, use this command to enable the RIPng automatically.

**Configuration Examples** The following example enables the RIPng on the interface 0/0:

```
Ruijie(config)# interface ethernet 0/0
Ruijie(config-if)# ipv6 rip enable
```

**Related  
Commands**

| Command | Description |

| N/A     | N/A         |

**Platform** N/A

**Description**

## 6.8 ipv6 rip metric-offset

Use this command to set the interface metric value. Use the **no** form of this command to remove the metric configurations.

**ipv6 rip metric-offset** *value*

**no ipv6 rip metric-offset**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|              |                                                                                    |
|--------------|------------------------------------------------------------------------------------|
| <i>value</i> | Sets the interface metric value on the interface. The valid range is from 1 to 16. |
|--------------|------------------------------------------------------------------------------------|

**Defaults** 1

**Command mode** Interface configuration mode.

**Usage Guide** Before the route is added to the routing list, the interface metric value shall be upon the route metric. To this end, the interface metric value influences the route usage.

**Configuration** The following example sets the metric value of the interface Ethernet 0/1 as 5:

**Examples**

```
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ipv6 rip metric-offset 5
```

Description

## 6.10 passive-interface

Use this command to disable the interface to send update packets. Use the **no** form of this command to enable the interface to send update packets.

**passive-interface** { **default** | *interface-type interface-num* }

**no passive-interface** { **default** | *interface-type interface-num* }

| Parameter Description | Parameter                           | Description                                 |
|-----------------------|-------------------------------------|---------------------------------------------|
|                       | <b>default</b>                      | Enables the passive mode on all interfaces. |
|                       | <i>interface-type interface-num</i> | Interface type and interface number.        |

**Defaults** No passive interface is configured by default.

**Command mode** Routing process configuration mode.

**Usage Guide** You can use the **passive-interface default** command to enable the passive mode on all interfaces. Then ,use the **no passive-interface** *interface-type interface-num* command to remove the specified interface from the passive mode.

**Configuration Examples** The following example enables the passive mode on all interfaces and remove interface ethernet 0/0 from the passive mode:

```
Ruijie(config-router)# passive-interface default
Ruijie(config-router)# no passive-interface ethernet 0/0
```

Description

## 6.11 redistribute

Use this command to redistribute the route of other routing protocols to RIPng. Use the **no** form of this

command to remove the redistribution configuration.

**redistribute** { **bgp** | **connected** | **isis** [ *area-tag* ] | **ospf** *process-id* | **static** } [ **metric** *metric-value* | **route-map** *route-map-name* ]

**no redistribute** { **bgp** | **connected** | **isis** [ *area-tag* ] | **ospf** *process-id* | **static** } [ **metric** *metric-value* | **route-map** *route-map-name* ]

#### Parameter Description

| Parameter                              | Description                                                                                                                        |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>bgp</b>                             | Redistributes the BGP routes to RIPng.                                                                                             |
| <b>connected</b>                       | Redistributes the connected routes to RIPng.                                                                                       |
| <b>isis</b> [ <i>area-tag</i> ]        | Redistributes the ISIS routes to RIPng.<br><i>area-tag</i> indicates the ISIS process number.                                      |
| <b>ospf</b> <i>process-id</i>          | Redistributes the OSPF routes to RIPng.<br><i>process-id</i> indicates the OSPF process number, and the range is from 1 to 65,535. |
| <b>static</b>                          | Redistributes the static routes to RIPng.                                                                                          |
| <b>metric</b> <i>metric-value</i>      | (Optional) Sets the metric value for the route redistributed to RIPng.                                                             |
| <b>route-map</b> <i>route-map-name</i> | (Optional) Sets the redistribution route filtering.                                                                                |

#### Defaults

By default, the routes of other routing protocols are not redistributed.

If the **default-metric** command is not configured, the default metric value is 1;

By default, the **route-map** is not configured;

By default, all sub-type routes in the specified routing process are redistributed.

#### Command mode

Routing process configuration mode.

#### Usage Guide

This command is used to redistribute the external routes to RIPng.

It is unnecessary to transform the metric of one routing protocol into another routing protocol in the process of the route redistribution, for the metric calculation methods of the different routing protocols are different. The RIP and OSPF metric calculations are incomparable for the reason that the RIP metric calculation is hop-based while the OSPF one is bandwidth-based.

The instance, from where the routing information is redistributed to the RIPng, must be specified in the process of configuring the multi-instance protocol redistribution.

#### Configuration Examples

The following example redistributes the static route, use the route map *mymap* to filter and set the metric value as 8:

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# redistribute static route-map
mymap metric 8
```

|-----------------------|---------------------------------------------|
| <b>default-metric</b> | Defines the default RIPng metric value when |

|                        |                                           |
|------------------------|-------------------------------------------|
|                        | redistributing other routing protocols.   |
| <b>distribute-list</b> | Filters the RIPng routing update packets. |

**Platform** N/A

**Description**

## 6.12 show ipv6 rip

Use this command to show the parameters and each statistical information of the RIPng routing protocol process.

**show ipv6 rip**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration Examples**

```
Ruijie# show ipv6 rip
Routing Protocol is "RIPng"
  Sending updates every 10 seconds with +/-50%, next due in 8 seconds
  Timeout after 30 seconds, garbage collect after 60 seconds
  Outgoing update filter list for all interface is:
    distribute-list prefix aa out
  Incoming update filter list for all interface is: not set
  Default redistribution metric is 1
  Default distance is 120
  Redistribution:
    Redistributing protocol connected route-map rm
    Redistributing protocol static
    Redistributing protocol ospf 1
  Default version control: send version 1, receive version 1
  Interface          Send  Recv
    VLAN 1           1    1
    Loopback 1       1    1
  Routing Information Sources:
    None
```

| Related Commands | Command              | Description                                                                    |
|------------------|----------------------|--------------------------------------------------------------------------------|
|                  | <b>show ipv6 rip</b> | Displays the parameters and each statistical information of the RIPng process. |

**Description**

## 6.14 split-horizon

Use the **split-horizon** command to enable the RIPng split-horizon function in routing process configuration mode. Use the **no** form of this command to disable this function. Use the **split-horizon poisoned-reverse** command to enable the RIPng poisoned reverse horizontal split function in routing process configuration mode. Use the **no** form of this command to disable this function.

**split-horizon poisoned-reverse**

**no split-horizon poisoned-reverse**

| Parameter<br>Description | Parameter               | Description                                               |
|--------------------------|-------------------------|-----------------------------------------------------------|
|                          | <b>poisoned-reverse</b> | (Optional) Enables the poisoned-reverse horizontal split. |

**Defaults** RIPng split horizon is enabled by default.

**Command mode** Routing process configuration mode.

**Usage Guide** In the process of packet updating, split-horizon function prevents some routing information from being advertised through the interface learning those routing information. The poisoned reverse horizontal split function advertises some routing information to the interface learning those routing information, and the metric value is set as 16. The RIPng routing protocol belongs to the distance vector routing protocol, so the horizontal split shall be noticed in the actual application. You can use the **show ipv6 rip** command to determine whether the RIPng split-horizon function is enabled or not.

**Configuration Examples** The following example disables the RIPng horizontal split:

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# no split-horizon
```

**Description**

## 6.15 timers

Use this command to adjust the RIPng timer. Use the **no** form of this command to restore the default settings.

**timers** *update invalid flush*

**no timers**

| Parameter<br>Description | Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>update</i>  | Sets the routing update time, in seconds. The update parameter defines the period of sending the routing update packets by the device. The invalid and flush parameter reset once the update packets are received.                                                                                                                                                                                                                                              |
|                          | <i>invalid</i> | Sets the routing invalid time, in seconds, starting from receiving the last valid update packet. The invalid parameter defines the invalid time for the un-updated routing in the routing list. The routing invalid time shall be three times larger than the routing update time. The routing will be invalid if no update packets are received within the routing invalid time, and it will reset if the update packets are received within the invalid time. |
|                          | <i>flush</i>   | Sets the routing flush time, in seconds, starting from RIPng entering to invalid state. The invalid routing will be removed from the routing list if the flush time expires.                                                                                                                                                                                                                                                                                    |

**Defaults** The default update time is 30 seconds; the default invalid time is 180 seconds; and the default flush time is 120 seconds.

**Command mode** Routing process configuration mode.

**Usage Guide** Adjusting the above time may speed up the RIPng convergence time and the troubleshooting time. The RIPng time must be consistent for the devices connecting to the same network. You are not recommended to adjust the RIP time, except for the specific requirement.

Use the **show ipv6 rip** command to view the current RIPng time parameter setting.

In the low-speed link, with the short time configured, large amount of the update packets consumes a lot of bandwidth. Generally, the short time can be configured in the Ethernet or 2Mbps-higher line to shorten the convergence time of the network routing.

**Configuration Examples** The following example sends the RIP update packets every 10 seconds. The routing will be invalid if no update packets are received within 30 seconds, and the routing will be removed after being invalid for 90 seconds.

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# timers 10 30 90
```

## 7 NSM Commands

### 7.1 clear ip mroute

Use this command to clear the route cache.

**clear ip route** [ **vrf** *vrf\_name* ] { \* | **network** [ *netmask* ] | }

**Parameter**  
**description**

| Parameter                  | Description                                                                                                                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf_name</i> | (Optional) Specifies the route cache of the specified VRF instance. If no VRF is specified, the route cache of all VRF instances is cleared.                                         |
| *                          | Clears all route cache.                                                                                                                                                              |
| <b>network</b>             | Specifies the route cache of the network or subnet.                                                                                                                                  |
| <i>netmask</i>             | (Optional) Subnet mask. If no subnet mask is specified, the longest match principle is used when you match <i>network</i> with the route. The cache of the longest match is cleared. |

**Command mode** Privileged EXEC mode.

**Usage guidelines**

Clearing route cache clears the corresponding routes and triggers the routing protocol relearning. Please note that clearing all route cache leads to temporary network disconnection.

**Examples**

The following example clears the cache of the route which is the longest match with IP address 192.168.12.0.

```
clear ip route 192.168.12.0
```

**Related commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform**

**description** This command is not supported on layer 2 devices.

### 7.2 clear ip route arp scan times

Use this command to clear the ARP request transmission count and start counting again.

**clear ip route arp scan times**

**Parameter**  
**Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Command** Privileged EXEC mode

**Mode**

**Default Level** 1

**Usage Guide** If the configured transmission count of ARP requests is 10 but the ARP still fails after the ARP request has been sent 10 times, the device no longer sends the ARP request. If you need to continue to send the ARP request, use this command to clear the count so that the device can continue to actively send the ARP request.

**Examples** The following example clears the transmission count of ARP requests.

```
Ruijie(config)# ip route scan arp times 10
Ruijie # clear ip route arp scan times
```

### 7.3 ip active-route real-time summary

Use this command to enable the real-time statistic of active routes. Use the **no** or **default** form of this command to restore the default settings.

**ip active-route real-time summary**

**no ip active-route real-time summary**

**default ip active-route real-time summary**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       |             |

**Defaults** The function is disabled by default.

**Command**

**Mode** Global configuration mode

**Usage Guide**

The real-time statistic of active routes mainly applies to the scenario when GRPC periodic samples or gets active routes, or run the show ip route summary command frequently, so as to reduce the statistic time of displaying active routes in large volume.

It is not recommended to enable the function in normal scenario, especially with high demand of routing convergence.

**Examples**

The following example enables/disables the real-time statistic of active routes.

```
Ruijie(config)# ip active-route real-time summary
Ruijie(config)# no ip active-route real-time summary
```

**Related**

| Command | Description |
|---------|-------------|
|---------|-------------|

|                 |     |     |
|-----------------|-----|-----|
| <b>Commands</b> | N/A | N/A |
|-----------------|-----|-----|

**Platform**

**Description** This command is supported on 2-layer devices.

## 7.4 ip default-gateway

Use this command to configure the default gateway IP address on 2-layer devices. Use the **no** or **default** form of this command to restore the default setting.

**ip default-gateway** *ip-address*

**no ip default-gateway**

**default ip default-gateway**

| Parameter          | Parameter         | Description                         |
|--------------------|-------------------|-------------------------------------|
| <b>Description</b> | <i>ip-address</i> | IPv4 address of the default gateway |

**Defaults** No gateway IP address is configured by default.

**Command**

**Mode** Global configuration mode

**Usage** When the device does not know the destination address of a packet, the device will forward the packet to the default gateway.

**Examples** The following example sets the IP address of default gateway to 192.168.1.1.

```
ip default-gateway 192.168.1.1
```

| Related         | Command | Description |
|-----------------|---------|-------------|
| <b>Commands</b> | N/A     | N/A         |

**Platform**

**Description** This command is supported on 2-layer devices.

## 7.5 ip default-network

Use this command to configure the default network globally. Use the **no** form of this command to restore the default setting.

**ip default-network** *network*

**no ip default-network** *network*

| Parameter          | Parameter      | Description     |
|--------------------|----------------|-----------------|
| <b>description</b> | <i>network</i> | Default network |

**Default configuration** The default is 0.0.0.0/0.

**Command mode** Global configuration mode.

**Usage guidelines** The goal of this command is to generate the default route. The default network must be reachable in the routing table, but not the directly connected network.

The default network always starts with an asterisk ("\*"), indicating that it is the candidate of the default route. If there is connected route and the route without the next hop in the default network, the default route must be a static route.

**Examples** The following example sets 192.168.100.0 as the default network. Since the static route to the network is configured, the device will automatically generate a default route.

```
ip route 192.168.100.0 255.255.255.0 serial 0/1
ip default-network 192.168.100.0
```

The following example sets 200.200.200.0 as the default network. The route becomes the default one only when it is available in the routing table.

```
ip default-network 200.200.200.0
```

Related commands

| Command       | Description                 |
|---------------|-----------------------------|
| show ip route | Displays the routing table. |

## 7.6 ip fast-reroute static route-map

Use this command to enable static fast reroute. Use the **no** or **default** form of this command to restore the default setting.

**ip fast-reroute** [ **vrf** *vrf-name* ] **static route-map** *route-map-name*

**no ip fast-reroute** [ **vrf** *vrf-name* ]

**default ip fast-reroute** [ **vrf** *vrf-name* ]

| Parameter          | Parameter                  | Description  |
|--------------------|----------------------------|--------------|
| <b>Description</b> | <b>vrf</b> <i>vrf-name</i> | VRF          |
|                    | <i>route-map-name</i>      | Route map    |
|                    | <b>static</b>              | Backup route |

**Default** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage guideline** Fast reroute provides an active next-hop and a backup one. If the active next-hop fails, the backup next-hop is used for forwarding.

To enhance the performance of fast reroute, enable the BFD detection function for the active next-hop. For interfaces that are up or down, to shorten the interruption time of fast reroute, configure **carrier-delay 0** in the interface configuration mode of the active outbound interface to optimize the performance.

For static fast reroute, if the active next-hop fails, the backup next-hop is used for forwarding.

**Examples** The following example sets the backup next-hop of all static routes to 192.168.1.2 through the outbound interface of GigabitEthernet 0/1.

```
Ruijie(config)# route-map fast-reroute
Ruijie(config-route-map)# set fast-reroute backup-interface GigabitEthernet 0/1
Ruijie(config-route-map)# exit
Ruijie(config)# ip fast-reroute static route-map fast-reroute
```

**Related command**

| Command             | Description                   |
|---------------------|-------------------------------|
| <b>fast-reroute</b> | Configures OSPF fast reroute. |

**Platform Description**

This command is not supported on 2-layer devices.

## 7.7 ip recur-route fastswitch-nexthop

Use this command to enable the recursive routing fast convergence.

**ip recur-route fastswitch-nexthop**

Use the **no** form of this command to disable the recursive routing fast convergence.

**no ip recur-route fastswitch-nexthop**

Use the **default** form of this command to restore the default configuration.

**default ip recur-route fastswitch-nexthop**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

The recursive routing fast convergence is disabled by default.

**Command Mode**

Global configuration mode

**Default Level** 14

## Usage Guide

As shown in the figure above, the DUT establishes IS-IS neighbor relationships with SW1 and SW2, SW1 and SW2 separately establish an IS-IS neighbor relationship with SW3 and SW4, and the DUT establishes IBGP neighbor relationships with SW3 and SW4. Service sites access the network via EBGp. In the scenario shown above, BGP routes may be recursed to IS-IS routes. When the link between SW1 and SW3 is disconnected, the IS-IS route will change and the BGP route that relies on the IS-IS route needs to be re-calculated. Before the calculation result is delivered to the forwarding plane, the BGP traffic from service site 1 to service site 2 still goes through the disconnected link between SW1 and SW3, resulting in traffic interruption. Traffic interruption duration = Link down time + Time required by the local IS-IS system to learn route deletion information + Time required by the local NSM system to receive IS-IS routing information + Time required for calculating the BGP route and delivering the result to the forwarding plane + Link switching time. The switching cannot be completed within 1 second. If the recursive routing fast convergence function is enabled, the traffic that needs to go through the disconnected link between SW1 and SW 3 can be switched to another normal link within 1 second.

## Examples

The following example enables/disables the recursive routing fast convergence.

```
Ruijie(config)# ip recur-route fastswitch-nexthop
Ruijie(config)# no ip recur-route fastswitch-nexthop
```

## 7.8 ip recur-route over default-route disable

Use this command to enable the function of forbidding recursion to the default route.

**ip recur-route over default-route disable**

Use the **no** form of this command to disable the function of forbidding recursion to the default route.

**no ip recur-route over default-route disable**

Use the **default** form of this command to restore the default configuration.

**default ip recur-route over default-route disable**

## Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

## Defaults

The function of forbidding recursion to the default route is disabled by default and routes are recursed to the default route by default.

**Command** Global configuration mode  
**Mode**

**Default Level** 14

#### Usage Guide

As shown in the scenario above, P1 establishes non-direct EBGp neighbor relationships with P2 and P3, the load balancing enables service traffic on P1 to be distributed to P4 through P2 and P3. The default route configured on P1 is used to access the extranet through the P1-P5 egress. When the link between P1 and P2 is faulty, it is expected that service traffic is switched to P3. However, some service traffic is guided to the P1-P5 egress due to the existence of the default route. The P1-P5 egress is not a service egress. As a result, some service traffic is lost and the convergence cannot be completed within 1s. With this command, when the link between P1 and P2 is faulty, traffic is completely switched to P3 and is not guided to P5, achieving convergence within 1s.

Note: When the egress of a default route is not the expected service egress, this command must be configured.

**Examples** The following example enables/disables the function of forbidding recursion to the default route.

```
Ruijie(config)# ip recur-route over default-route disable
Ruijie(config)# no ip recur-route over default-route disable
```

## 7.9 ip route

Use this command to configure a static route. Use the **no** or **default** form of this command to restore the default setting.

**ip route** [ **vrf** *vrf\_name* ] *network net-mask* { *ip-address* | *interface* [ *ip-address* ] } [ *distance* ] [ **tag** *tag* ] [ **permanent** | { **track** *object-number* | **arp** } ] [ **weight** *number* ] [ **description** *description-text* ] [ **disabled** | **enabled** ] [ **global** ] [ *bfd session-name* ]

**no ip route** [ **vrf** *vrf\_name* ] *network net-mask* { *ip-address* | *interface* [ *ip-address* ] } [ *distance* ]

**no ip route** [ **vrf** *vrf\_name* ] **all**

**default ip route** [ **vrf** *vrf\_name* ] *network net-mask* { *ip-address* | *interface* [ *ip-address* ] } [ *distance* ]

**Parameter  
Description**

| Parameter                                  | Description                                                                                                                                                                     |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf_name</i>                 | Name of the VRF, which can be the single protocol IPv4 VRF or configured IPv4 address family multi-protocol VRF.                                                                |
| <i>network</i>                             | Network address of the destination                                                                                                                                              |
| <i>net-mask</i>                            | Mask of the destination                                                                                                                                                         |
| <i>ip-address</i>                          | The next hop IP address of the static route                                                                                                                                     |
| <i>interface</i>                           | (Optional) The next hop egress of the static route                                                                                                                              |
| <i>distance</i>                            | (Optional) The administrative distance of the static route                                                                                                                      |
| <i>tag</i>                                 | (Optional) The tag of the static route                                                                                                                                          |
| <b>permanent</b>                           | (Optional) Permanent route ID                                                                                                                                                   |
| <b>track</b> <i>object-number</i>          | (Optional) Indicates correlation with Track. <i>object-number</i> indicates the ID of the track object. By default, the static route is not correlated with the Track function. |
| <b>weight</b> <i>number</i>                | (Optional) Indicates the weight of the static route. The weight is 1 by default.                                                                                                |
| <b>description</b> <i>description-text</i> | (Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.                |
| <b>disabled/enabled</b>                    | (Optional) Indicates the enable flag of the static route. The flag is enabled by default.                                                                                       |
| <b>global</b>                              | (Optional) Indicates that the next hop belongs to a global VRF. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> .                       |
| <b>arp</b>                                 | (Optional) Indicates that the next hop belongs to a global VRF. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> .                       |
| <b>bfd</b> <i>session-name</i>             | (Optional) Correlates with BFD session. <i>session-name</i> indicates the specified static BFD object name. By default, the static route is not correlated with BFD.            |

**Defaults** No static route is configured by default.

**Command Mode** Global configuration mode

**Usage Guide** The default administrative distance of the static route is 1. Setting the administrative distance allows the learnt dynamic route to overwrite the static route. Setting the administrative distance of the static route can enable route backup, which is called floating route in this case. For example, the administrative distance of the OSPF is 110. You can set its administrative distance to 125. Then the data can switch over the static route when the route running OSPF fails.

You can specify the VRF that the static route belongs to. The default weight of the static route is 1. To view the static route of non default weight, execute the `show ip route weight` command. The parameter `weight` is used to enable WCMP. When there are load-balanced routes to the destination, the device assigns data flows by their weights. The higher the weight of a route is, the more data flow the route carries. WCMP limit is generally 32 for routers. However, WCMP limit varies by switch models for their chipsets support different weights. When the sum of the weights of load balanced routes is beyond this weight limit, the excessive ones will not take effect.

Enablement/disablement shows the state of the static route. Disablement means the static route is not used for forwarding. The forwarding table used the permanent route until administrator deletes it. When you configure the static route on an Ethernet interface, do not set the next hop as an interface, for example, `ip route 0.0.0.0 0.0.0.0 Fastethernet 0/0`. In this case, the switch may consider that all unknown destination networks are directly connected to the Fastethernet 0/0. So it sends an ARP request to every destination host, which occupies many CPU and memory resources. It is not recommended to set the static route to an Ethernet interface.

Association between a static route and a track object can be specified. When association between a static route and a specified track object is configured and the advertised track object status is inactive, the static route does not take effect. If the advertised track object status is active, the static route takes effect based on another status. With association between a static route and a track object, the third-party status concerned by the track object is mainly used to determine whether the static route takes effect. Association between a static route and a track object cannot be used for routes with the permanent attribute.

Association between a static route and an ARP object can be specified. When association between a static route and an ARP object is configured and the ARP object corresponding to the next hop and egress of the route does not exist, the static route does not take effect. When the ARP object corresponding to the next hop and egress of the route exists, the static route takes effect based on another status. Association between a static route and an ARP object cannot be used for routes with the permanent attribute.

Association between a static route and a track object cannot be used together with association between a static route and an ARP object.

The following example adds a static route to the destination network of 172.16.100.0/24 whose next hop is 192.168.12.1 and administrative distance is 15.

```
ip route 172.16.199.0 255.255.255.0 192.168.12.1 155
```

#### Examples

If the static route has not a specific interface, data flows may be sent through other interface in case of interface failure. The following example configures data flows to be sent through fastethernet 0/0 to the destination network of 172.16.100.0/24.

```
ip route 172.16.199.0 255.255.255.0 fastethernet 0/0 192.168.12.1
```

**Commands** This command is not supported on 2-layer devices.

## 7.10 ip route aggregate

Use this command to configure an aggregate route.

**ip route aggregate** [ *vrf vrf\_name* ] *network netmask* **Null 0** [ *tag tag* ]

Use the following commands to delete a configured aggregate route/all aggregate route

**no ip route aggregate** [ *vrf vrf\_name* ] *network netmask* **Null 0**

**no ip route aggregate** [ *vrf vrf\_name* ] **all**

Use the following commands to restore a configured aggregate route/all aggregate route to the default settings.

**default ip route aggregate** [ *vrf vrf\_name* ] *network netmask* **Null 0**

**default ip route aggregate** [ *vrf vrf\_name* ] **all**

**Parameter  
Description**

| Parameter           | Description                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf vrf_name</i> | (Optional) Route VRF which can be the single protocol IPv4 VRF or configured IPv4 address family multi-protocol VRF. Global VRF by default. |
| <i>network</i>      | Network address of the destination                                                                                                          |
| <i>netmask</i>      | Mask of the destination                                                                                                                     |
| <b>Null 0</b>       | Not configure the next hop IP address and egress of the aggregate route                                                                     |
| <i>tag</i>          | (Optional) The tag of the aggregate route, 0 by default                                                                                     |
| <b>all</b>          | (Optional) Delete all aggregate routes of the specific VRF.                                                                                 |

**Defaults** No aggregate route is configured by default.

**Command  
Mode** Global configuration mode

**Usage Guide** The command takes effect in OPENCONF YANG to record the configuration of aggregate routes.  
The actual effect is like black hole route.

**Examples** The following example adds an aggregate route to the destination network of 1.1.1.0/24 whose TAG is 32.

```
ip route aggregate 1.1.1.0 255.255.255.0 Null 0 tag 32
```

Commands** This command is not supported on 2-layer devices.

## 7.11 ip route arp-to-host delay-time

Use this command to configure the delayed redistribution of ARP-to-host route. Use the **no** or **default** form of this command to restore the default setting.

**ip route arp-to-host delay-time** *time-number*

**no ip route arp-to-host delay-time**

**default ip route arp-to-host delay-time**

|                  | Parameter                                                                                                                                                                                                         | Description                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Parameter        |                                                                                                                                                                                                                   |                                                                                                                                       |
| Description      | <i>time-number</i>                                                                                                                                                                                                | Indicates the time of the delayed redistribution of ARP-to-host. The unit is second, the range is 1-1000, and the default value is 0. |
| Defaults         | The delayed redistribution of ARP-to-host rout is disabled by default.                                                                                                                                            |                                                                                                                                       |
| Command Mode     | Global configuration mode                                                                                                                                                                                         |                                                                                                                                       |
| Usage Guide      | After the delayed redistribution is configured, the redistribution will be delayed according to the specified time for the ARP packets. The redistribution route of ARP failure packet is immediately advertised. |                                                                                                                                       |
| Examples         | The following example delays the redistribution of arp-to-host route to protocol module for 10 seconds. <div>Ruijie(config)# ip route arp-to-host delay-time 10</div>                                             |                                                                                                                                       |
| Related Commands | N/A                                                                                                                                                                                                               |                                                                                                                                       |
| Platform         |                                                                                                                                                                                                                   |                                                                                                                                       |
| Description      | This command is not supported on 2-layer devices.                                                                                                                                                                 |                                                                                                                                       |

## 7.12 ip route arp-to-host interface

Use this command to enable ARP-to-host conversion. Use the **no** or **default** form of this command to restore the default setting.

**ip route arp-to-host interface** *interface-name*

**no ip route arp-to-host interface** *interface-name*

**default ip route arp-to-host interface** *interface-name*

| Parameter    | Parameter                                             | Description                     |
|--------------|-------------------------------------------------------|---------------------------------|
| Description  | <i>interface-name</i>                                 | Indicates name of an interface. |
| Defaults     | The ARP-to-host conversion is disabled by default.    |                                 |
| Command Mode | Global configuration mode                             |                                 |
| Usage Guide  | Please make sure the interface is a layer 3 interface |                                 |
| Examples     | The following example enable ARP-to-host conversion.  |                                 |

```
Ruijie(config)# ip route arp-to-host interface vlan 40
```

**Related****Commands** N/A**Platform****Description** This command is not supported on 2-layer devices.

## 7.13 ip route arp-to-host tag

Use this command to configure the *tag* attribute of ARP-to-host conversion. Use the **no** or **default** form of this command to restore the default setting.

**ip route arp-to-host tag** *tag-number***no ip route arp-to-host tag** *tag-number***default ip route arp-to-host tag** *tag-number*

| Parameter   | Parameter         | Description                                 |
|-------------|-------------------|---------------------------------------------|
| Description | <i>tag-number</i> | Indicates value of tag. It is 0 by default. |

**Defaults** It is disabled by default.**Command Mode**

Global configuration mode

**Usage Guide** N/A**Examples**

The following example configures the tag attribute of ARP-to-host conversion.

```
Ruijie(config)# ip route arp-to-host tag 5
```

**Related****Commands** N/A**Platform****Description** This command is not supported on 2-layer devices.

## 7.14 ip route delay-uninstall times

Use this command to configure the buffer time of batch deleting routes.

**ip route delay-uninstall times** *number*

Use the **no** form of this command to delete the buffer time and restore the default configuration.

**no ip route delay-uninstall times**

Use the **default** form of this command to restore the default configuration.

**default ip route delay-uninstall times**

**Parameter  
Description**

| Parameter | Description                                                                    |
|-----------|--------------------------------------------------------------------------------|
| number    | 0 by default, which indicates deleting the route immediately. Range: 1-100 (s) |

**Defaults**

The function is disabled by default.

**Command  
Mode**

Global configuration mode

**Default Level** 14

**Usage Guide**

By configuring the buffer time of batch deleting routes in the case of large route amount, the route converge speed of BGP update can be improved. It is recommended to set the time as 5s; if the route amount is very large, the time can be set larger.

**Examples**

The following example configures the buffer time of batch deleting routes and disables the function.

```
Ruijie(config)# ip route delay-uninstall times 5
Ruijie(config)# no ip route delay-uninstall times
```

**Platform**

**Description** This command is not supported on 2-layer devices.

## 7.15 ip route notify delete always

Use this command to enable the function of directly deleting BGP routes during GR.

**ip route notify delete always**

Use the **no** form of this command to disable the function of directly deleting BGP routes.

**no ip route notify delete always**

Use the **default** form of this command to restore the default configuration.

**default ip route notify delete always**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

The function of directly deleting BGP routes is disabled by default.

|                      |                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Command Mode</b>  | Global configuration mode                                                                                                                                                                                       |
| <b>Default Level</b> | 14                                                                                                                                                                                                              |
| <b>Usage Guide</b>   | If the function is enabled, the BGP route deletion configuration takes effect immediately during GR to prevent routing black hole.                                                                              |
| <b>Examples</b>      | <p>The following example enables/disables the function of directly deleting BGP routes during GR.</p> <pre>Ruijie(config)# ip route notify delete always Ruijie(config)# no ip route notify delete always</pre> |

## 7.16 ip route scan arp interval

Use this command to set the interval for actively sending ARP requests when ARP fails after static routing support for ARP is configured.

**ip route scan arp interval** *number*

Use the **no** form of this command to delete the configured interval for actively sending ARP requests and restore the default value.

**no ip route scan arp interval**

Use the **default** form of this command to restore the default configuration.

**default ip route scan arp interval**

| Parameter Description | Parameter | Description                                                                                        |
|-----------------------|-----------|----------------------------------------------------------------------------------------------------|
|                       | number    | Interval. The value range is <b>5</b> to <b>120</b> in seconds and the default value is <b>5</b> . |

**Defaults** The transmission interval is not configured by default. ARP requests are sent at an interval of 5 seconds by default.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** After the static routing support for ARP is configured, when ARP fails due to a link failure or other causes, the device actively transmits ARP requests and the transmission interval can be configured. ARP requests are transmitted at an interval of 5 seconds by default.

**Examples** The following example configures the interval for actively sending ARP requests.

```
Ruijie(config)# ip route scan arp interval 10
Ruijie(config)# no ip route scan arp interval
```

## 7.17 ip route scan arp times

Use this command to set the number of times of actively sending ARP requests when ARP fails after static routing support for ARP is configured.

**ip route scan arp times** *number*

Use the **no** form of this command to delete the configured number of times of actively sending ARP requests and restore the default value.

**no ip route scan arp times**

Use the **default** form of this command to restore the default configuration.

**default ip route scan arp times**

| Parameter<br>Description | Parameter | Description                                                                                    |
|--------------------------|-----------|------------------------------------------------------------------------------------------------|
|                          | number    | Interval. The value range is <b>1</b> to <b>65,535</b> and the default value is <b>65535</b> . |

**Defaults** The transmission count is not configured by default. The default value is **65535**.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** After the static routing support for ARP is configured, when ARP fails due to a link failure or other causes, the device actively transmits ARP requests and the transmission count can be configured. ARP requests are transmitted 65535 times by default.

**Examples** The following example configures the number of times of actively sending ARP requests.

```
Ruijie(config)# ip route scan arp times 10
Ruijie(config)# no ip route scan arp times
```

## 7.18 ip route static bfd

Use this command to correlate the static route with BFD. Use the **no** or **default** form of this command to restore the default setting.

**ip route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**no ip route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**default ip route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

| Parameter<br>description | Parameter                  | Description                                                                          |
|--------------------------|----------------------------|--------------------------------------------------------------------------------------|
|                          | <b>vrf</b> <i>vrf-name</i> | (Optional) Specifies the VRF name of the static route. By default, it is global VRF, |

|                                                  |                                                                                                                                                                                                             |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | Interface type and interface number.                                                                                                                                                                        |
| <i>gateway</i>                                   | Specifies the gateway IP address, that is, the BFD neighbor IP address. If the next hop of the static route is the neighbor, the BFD will detect whether this neighbor is reachable.                        |
| <b>source</b> <i>ip-address</i>                  | (Optional) The source IP address of the BFD session. If the neighbor device is multi hops away, you should specify the source IP address for the BFD session. No source IP address is specified by default. |

**Default****configuration**

The static address is not correlated with BFD by default.

**Command mode**

Global configuration mode.

**Usage guidelines**

Please make sure the BFD session parameters have been configured before executing this command.

**Examples**

The following example correlates the static route with BFD, and detects the reachability of path to the neighbor 172.16.0.2.

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# no switchport // No need to
perform this command on the router.
Ruijie(config-if-GigabitEthernet 0/1)# ip address 172.16.0.1
255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# bfd interval 50 min_rx 50
multiplier 3
Ruijie(config-if-GigabitEthernet 0/1)#exit
Ruijie(config)# ip route static bfd GigabitEthernet 0/1 172.16.0.2
Ruijie(config)# ip route 10.0.0.0 255.0.0.0 GigabitEthernet 0/1
172.16.0.2
```

**Related commands**

N/A

**Platform description**

This command is not supported on Layer 2 devices.

## 7.19 ip route static inter-vrf

Use this command to enable packets to be forwarded over VRF instances through the static route. Use the **no** or **default** form of this command to disable this function.

**ip route static inter-vrf**

**no ip route static inter-vrf**

**default ip route static inter-vrf**

| Parameter             | Parameter                                                                                                                                                                                                                                                                                                                                                                                                                                      | Description |

## 7.21 ipv6 fast-reroute static route-map

Use this command to enable an IPv6 static fast reroute. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 fast-reroute** [ **vrf** *vrf-name* ] **static route-map** *route-map-name*

**no ipv6 fast-reroute** [ **vrf** *vrf-name* ]

**default ipv6 fast-reroute** [ **vrf** *vrf-name* ]

| Parameter                              | Description                                                                                                      |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Parameter</b><br><b>Description</b> |                                                                                                                  |
| <i>vrf-name</i>                        | (Optional) Name of VRF. When the name of VRF is not specified, the configuration takes effect in the global VRF. |
| <i>route-map-name</i>                  | Route map of static fast reroute                                                                                 |
| <b>static</b>                          | Back up the route map                                                                                            |

**Defaults** Static fast reroute is not enabled by default.

**Command Mode** Global configuration mode

The fast reroute delivers the primary route and backup route at the same time. When the primary link fails, it forwards packets by switching to the backup route, thus shortening the communication interruption time.

**Usage Guide** To improve the switching performance of fast reroute, you can enable BFD to check whether the next hop is reachable. In order to shorten the forwarding interruption time, you can configure **carrier-delay 0** on the primary link export in the interface mode to achieve the fastest switching performance. For static fast reroute, when the primary next hop fails and the backup next hop is valid, the backup next hop becomes the primary next hop for forwarding.

The following example configures the backup next hop of static route as 2001::1, through the interface GigabitEthernet 0/1

### Examples

```
Ruijie(config)# route-map fast-reroute
Ruijie(config-route-map)# set ipv6 fast-reroute
backup-interface GigabitEthernet 0/1 backup-nexthop 2001::1
Ruijie(config-route-map)# exit
Ruijie(config)# ipv6 fast-reroute static route-map
fast-reroute
```

### Platform

**Description** This command is not supported on 2-layer devices.

## 7.22 ipv6 recur-route fastswitch-nexthop

Use this command to enable the fast convergence of a recursive route. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 recur-route fastswitch-nexthop**

**no ipv6 recur-route fastswitch-nexthop**

**default ipv6 recur-route fastswitch-nexthop**

| Parameter | Description |
|-----------|-------------|
| N/A       |             |

**Defaults** Disabled by default.

**Command Mode** Global configuration mode

### Usage Guide

As shown in the figure above, DUT establishes ISIS neighbors with SW1 and SW2, SW1 and SW2 establish ISIS neighbors with SW3 and SW4, and DUT establishes IBGP neighbors with SW3 and SW4. The service site is accessed through EBGP.

The BGP route is recursively sent to the ISIS route. When the SW1 and SW3 are disconnected, the ISIS route is changed, so the GP route that depends on the ISIS route needs to be recalculated.

Before the calculation result is sent to the forwarding plane, BGP traffic from the service site1 to the service site2 still goes through the disconnected link between SW1 and SW3, resulting in the flow interruption. Interruption time = link down + local ISIS learns the route deletion information + local NSM receives the ISIS routing information + calculates and delivers the BGP route to the forwarding plane + switching link, which cannot meet the requirement of switching within 1 s.

If the fast switching of recursive route is enabled, the traffic going through the disconnected link between SW1 and SW3 can be switched to other normal links within 1 s.

### Examples

The following example enables/disables the fast convergence of recursive route

```
Ruijie(config)# ipv6 recur-route fastswitch-nexthop
Ruijie(config)# no ipv6 recur-route fastswitch-nexthop
```

### Platform

**Description** This command is not supported on 2-layer devices.

## 7.23 ip static route-limit

Use this command to set the upper threshold of the static route. Use the **no** form of this command to restore the default setting.

**ip static route-limit** { number | **default-vrf** number | **vrf** vrf-name number }

**no ip static route-limit** [ **default-vrf** ] [ [ **vrf** vrf-name ] ]

| Parameter   | Parameter                  | Description                                                  |
|-------------|----------------------------|--------------------------------------------------------------|
| description | <i>number</i>              | Upper threshold of static routes                             |
|             | <b>default-vrf</b> number  | Upper threshold of default VRF static routes, range: 1-10000 |
|             | <b>vrf</b> vrf-name number | Upper threshold of VRF static routes, range: 1-10000.        |

**Default configuration** The default is 1024.

**Command mode** Global configuration mode.

**Usage guidelines** The goal is to control the number of static routes. You can view the upper threshold of the configured non-default static routes with the show running config command.

The following example sets the upper threshold of the static routes/default VRF static routes/VRF test static routes to 9000/2000/1000, and then restores the the default values.

### Examples

```
Ruijie(config)#ip static route-limit ?
  <1-1000000> Global limit value(default value: 1024)
  default-vrf Default Routing/Forwarding instance
  vrf         VPN Routing/Forwarding instance
Ruijie(config)# ip static route-limit 9000
Ruijie(config)# ip static route-limit default-vrf 2000
Ruijie(config)# ip static route-limit vrf test 1000
Ruijie(config)# no ip static route-limit
Ruijie(config)# no ip static route-limit default-vrf
Ruijie(config)# no ip static route-limit vrf test
```

**Related commands** N/A

**Platform description** This command is not supported on Layer 2 devices.

## 7.24 ipv6 default-gateway

Use this command to configure the default gateway IPv6 address on 2-layer devices. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 default-gateway** *ipv6-address*

**no ipv6 default-gateway**

**default ipv6 default-gateway**

**Parameter  
Description**

| Parameter           | Description                            |
|---------------------|----------------------------------------|
| <i>ipv6-address</i> | Sets the default gateway IPv6 address. |

**Defaults** No gateway IPv6 address is configured by default.

**Command  
Mode** Global configuration mode

**Usage Guide** When the device does not know the destination address of a packet, the device will forward the packet to the default gateway. Use the command **show ipv6 redirects** to display default gateway configuration.

**Examples** The following example sets the default gateway IPv6 address to 10::1.

```
Ruijie(config)# ipv6 default-gateway 10::1
```

**Platform  
Description** This command is not supported on 2-layer devices or 3-layer devices configured with the **no ip routing** command.

## 7.25 ipv6 route

Use this command to configure an ipv6 static route. Use the **no** form of this command to restore the default setting.

**ipv6 route** [ **vrf** *vrf-name* ] *ipv6-prefix* / *prefix-length* { *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] | *interface* [ *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] ] } [ *distance* ] [ **tag** *tag* ] [ **weight** *number* ] [ **description** *description-text* ] [ **bfd** *session-name* ]

**no ipv6 route** [ **vrf** *vrf-name* ] *ipv6-prefix* / *prefix-length* { *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] | *interface* [ *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] ] } [ *distance* ]

**no ipv6 route** [ **vrf** *vrf\_name* ] **all**

**default ipv6 route** [ **vrf** *vrf-name* ] *ipv6-prefix* / *prefix-length* { *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] | *interface* [ *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] ] } [ *distance* ]

**default ipv6 route** [ **vrf** *vrf\_name* ] **all**

**Parameter  
description**

| Parameter                  | Description                                                                       |
|----------------------------|-----------------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i> | Name of VRF, which must be the configured IPv6 address family multi-protocol VRF. |
| <i>ipv6-prefix</i>         | IPv6 prefix                                                                       |
| <i>prefix-length</i>       | Mask length of the destination                                                    |
| <i>ipv6-address</i>        | The next hop IP address of the static route                                       |
| <i>interface</i>           | (Optional) The next hop egress of the static route                                |
| <b>nexthop-vrf</b>         | VRF the nexthop belongs, which must be the configured IPv6 address                |

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name1</i>                              | family multi-protocol VRF.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>distance</i>                               | (Optional) The administrative distance of the static route. The default is 1.                                                                                                                                                                                                                                                                                                                                                                |
| <i>tag</i>                                    | (Optional) The tag value of the static route. The default is 0.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>weight</b> <i>number</i>                   | (Optional) Indicates the weight of the static route, which must be specified when you configure equal-cost routes. The weight ranges from 1 to 8. When the weights of all equal-cost routes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default. |
| <b>Description</b><br><i>description-text</i> | (Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.                                                                                                                                                                                                                                                                             |
| <b>all</b>                                    | (Optional) Deletes all static IPv6 routes of the specified VRF.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>bfd</b> <i>session-name</i>                | (Optional) Correlates with BFD session. <i>session-name</i> indicates the specified static BFD object name. By default, the static route is not correlated with BFD.                                                                                                                                                                                                                                                                         |

#### Default configuration

No IPv6 static route is configured by default.

#### Command mode

Global configuration mode.

#### Usage guidelines

When the multi-protocol VRF deletes the IPv6 address family, the IPv6 static route of VRF that the route or nexthop belongs is deleted.

If the VRF of the IPv6 static route interface is not same as the nexthop's VRF, then this IPv6 static route takes no effect.

The default administrative distance of the static route is 1. Setting the administrative distance allows the learnt dynamic route to overwrite the static route. Setting the administrative distance of the static route can enable route backup, which is called floating route in this case. For example, the administrative distance of the OSPF is 110. You can set its administrative distance to 125. Then the data can switch over the static route when the route running OSPF fails.

#### Examples

The following example adds a static route to the destination network of 2001::/64 whose next hop is 2002::2 and administrative distance is 115.

```
ipv6 route 2001::/64 2002::2 115
```

If the static route has not a specific interface, data flows may be sent through other interface in case of interface failure. The following example configures that data flows are sent through fastethernet 0/0 to the destination network of 2001::/64.

```
ipv6 route 2001::/64 fastethernet 0/0 2002::2
```

| show ipv6 route | Displays IPv6 routing table. |
|-----------------|------------------------------|

**Platform description** This command is not supported on Layer 2 devices.

## 7.26 ipv6 route nd-to-route delay-time

Use this command to configure the delayed redistribution of nd-to-route. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 route nd-to-route delay-time** *time-number*

**no ipv6 route nd-to-route delay-time**

**default ipv6 route nd-to-route delay-time**

| Parameter                              | Description                                                                                                                                                |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameter</b><br><b>Description</b> | <i>time-number</i><br>Indicates the time of the delayed redistribution of nd-to-route. The unit is second, the range is 1-1000, and the default value is 0 |

**Defaults** The delayed redistribution of nd-to-route is not configured by default.

**Command Mode** Global configuration mode

**Usage Guide** After the delayed redistribution is configured, the redistribution will be delayed according to the specified time for the ND packet. The redistribution route of ND failure packet is immediately advertised.

**Examples** The following example delays the redistribution of nd-to-route to protocol module for 10 seconds.

```
Ruijie(config)# ipv6 route nd-to-route delay-time 10
```

**Related Commands** N/A

**Platform Description** This command is not supported on 2-layer devices.

## 7.27 ipv6 route nd-to-route interface

Use this command to enable nd-to-route on a specified interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 route nd-to-route interface** *interface-name* [**ipv6-prefix** *X:X:X:X/0-128*] [**prefix-len** *masklen*]

**no ipv6 route nd-to-route interface** *interface-name* [**ipv6-prefix** *X:X:X:X/0-128*] [**prefix-len**]

**default ipv6 route nd-to-route interface** *interface-name* [**ipv6-prefix** *X:X:X:X/0-128*] [**prefix-len**]

| Parameter<br>Description | Parameter                       | Description                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>interface-name</i>           | The interface name.                                                                                                                                                                                                                                                                                                                                 |
|                          | <i>X:X:X:X::X/&lt;0-128&gt;</i> | Ipv6 network segment. If the nd entries match this network segment, the route is converted according to the mask specified by this network segment. If the network segment does not specify a mask, the default mask is 128.                                                                                                                        |
|                          | masklen                         | The mask length of the nd-to-route. The range is 0 to 128, and the default value is 128. If an IPv6 network segment is specified, it is longer than the mask length of configured network segment. If no IPv6 network segment is specified, it is longer than the mask length of IPv6 address on the interface. Otherwise, the configuration fails. |

**Defaults** The nd-to-route on a specified interface is not configured by default.

**Command Mode** Global configuration mode

**Usage Guide**  Please make sure that the interface is a Layer-3 interface.

If the IPv6 network segment and prefix-len are not specified, the ND learned on the default interface generates a 128-bit route. If no IPv6 network segment is specified but prefix-len is specified, ND on the interface generate the specified prefix- len. If IPv6 network segment is specified but prefix-len is not specified, the network segment generates a 128-bit route by default. If the network segment and the prefix-len are specified, the network segment is verified to match with the prefix when the ND is learned, and then the prefix-len is generated. If the network segment and prefix-len are specified, and the prefix-len of an unspecified network segment is configured, the specified interface generates the route according to its prefix-len, while the unspecified interface generates the route according to the unspecified prefix-len.

If you configure the IPv6 address of an interface before configuring the prefix-len of the interface address to generate a route with fixed-length mask, a configuration error occurs when the prefix-len is shorter than or equal to the mask of the IPv6 address. The prefix-len command fails. For example, first configure IPv6 address 10::1/64 on the interface of vlan 40, and then configure ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58 prefix-len 60 in the global configuration mode, the configuration fails.

If you configure the IPv6 address of an interface before configuring the prefix-len of an unspecified network segment, a configuration error occurs when the prefix-len is shorter than or equal to the mask of any of the IPv6 addresses on the interface. The prefix-len configuration command for the unspecified network segment fails. For example, first configure IPv6 address 10::1/64 on the interface of vlan 40, and then configure ipv6 route nd-to-route interface vlan 40 prefix-len 60 in the global configuration mode, the configuration fails.

If you configure the prefix-len of an unspecified network segment before configuring the IPv6 address of this interface, syslog is displayed and the prefix-len configuration of unspecified network segment is

canceled when one of the IPv6 addresses is longer than or equal to the prefix-len of the unspecified network segment. For example, first configure `ipv6 route nd-to-route interface vlan 40 prefix-len 60` in the global configuration mode, and then configure address `10::1/64` on the interface of vlan 40, syslog alarm is displayed and the configuration `ipv6 route nd -to-route interface vlan 40 prefix-len 60` is deleted.

If you configure the prefix-len of the specified network segment and then configure the IPv6 address of the corresponding network segment, syslog is displayed and the prefix-len configuration of the specified network segment is canceled when the IPv6 address mask of the corresponding network segment is longer than or equal to the prefix-len of the specified network segment. For example, first configure `ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58 prefix-len 60` in the global configuration mode, and then configure the address `10::1/64` on the interface of vlan 40, the syslog alarm is displayed and the configuration `ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58 prefix-len 60` is deleted.

If you configure the prefix-len of unspecified network segment and the prefix-len of the specified network segment, and then configure the IPv6 address of the interface, please check whether the mask of each IPv6 address is longer than or equal to the prefix-len of the specified/unspecified network segment. Syslog is displayed and the prefix-len configuration of specified network segment is canceled when the mask of each IPv6 address is longer than or equal to the prefix-len of the corresponding network segment. Syslog is displayed and the prefix-len configuration of unspecified network segment is canceled when the mask of each IPv6 address is longer than or equal to the prefix-len of unspecified network segment. For example, first configure `ipv6 route nd-to-route interface vlan 40 prefix-len 62` and `ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58 prefix-len 60`, and then configure address `10::1/64` on the interface of vlan 40, the syslog alarm is displayed and two configurations are deleted.

The following example enables nd-to-route on the interface vlan 40. NDs that match `10::1/58` network segment are converted to routes with a mask length of 110 bits. NDs that match `20::1/56` network segment are converted to routes with a mask length of 128 bits. Other NDs are converted to routes with a mask length of 120 bits.

#### Examples

```
Ruijie(config)# ipv6 route nd-to-route interface vlan 40 prefix-len 120
Ruijie(config)# ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58
prefix-len 110
Ruijie(config)# ipv6 route nd-to-route interface vlan 40 ipv6-prefix 20::1/56
```

#### Common

**Error** The Layer-3 interface is not in up status

#### Platform

**Description** This command is not supported on 2-layer devices.

## 7.28 ipv6 route nd-to-route tag

Use this command to configure the tag of nd-to-route. Use the **no** or **default** form of this command to restore

the default setting.

**ipv6 route nd-to-route tag** *tag-number*

**no ipv6 route nd-to-route**

**default ipv6 route nd-to-route tag**

| Parameter   | Parameter         | Description                                                                     |
|-------------|-------------------|---------------------------------------------------------------------------------|
| Description | <i>tag-number</i> | Indicates the tag value. The range is 1-4294967295, and the default value is 0. |

**Defaults** The tag of nd-to-route is not configured by default.

**Command Mode** Global configuration mode

#### Usage Guide

**Examples** The following example configures the tag of nd-to-route

```
Ruijie(config)# ipv6 route nd-to-route tag 5
```

**Related Commands** N/A

**Platform Description** This command is not supported on 2-layer devices.

## 7.29 ipv6 route nd-to-route warning-ignore

Use this command to ignore the warning of nd-to-route. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 route nd-to-route warning-ignore**

**no ipv6 route nd-to-route warning-ignore**

**default ipv6 route nd-to-route warning-ignore**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       |             |

**Defaults** The function of ignoring the warning of nd-to-route is not configured by default.

**Command Mode** Global configuration mode

**Usage Guide** After you configure to ignore the warning of nd-to-route, the alarm that the same PORT ND generates the same network segment route is ignored. If this command is not configured, the warning log that

the same PORT ND generates the same network segment route is printed (only once). The alarm that different ports generate the same network segment route is not controlled by this command.

**Examples**

The following example ignores the warning of nd-to-route

```
Ruijie(config)# ipv6 route nd-to-route warning-ignore
```

**Related**

**Commands** N/A

**Platform**

**Description** This command is not supported on 2-layer devices.

## 7.30 ipv6 route static bfd

Use this command to correlate the static route with BFD. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**no ipv6 route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**default ipv6 route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**Parameter  
description**

| Parameter                                        | Description                                                                                                                                                                                                 |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i>                       | (Optional) Specifies the VRF name of the static route. By default, it is global VRF,                                                                                                                        |
| <i>interface-type</i><br><i>interface-number</i> | Interface type and interface number.                                                                                                                                                                        |
| <i>gateway</i>                                   | Specifies the gateway IP address, that is, the BFD neighbor IP address. If the next hop of the static route is the neighbor, the BFD will detect whether this neighbor is reachable.                        |
| <b>source</b> <i>ipv6-address</i>                | (Optional) The source IP address of the BFD session. If the neighbor device is multi hops away, you should specify the source IP address for the BFD session. No source IP address is specified by default. |

**Default  
configuration**

The static route is not associated with BFD by default.

**Command mode**

Global configuration mode.

**Usage guidelines**

 Please make sure the BFD session parameters have been configured before executing this command.

**Examples**

The following example correlates the static route with BFD, and detects the reachability of

```

path to the neighbor 2001:1::2.
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# no switchport    //
Ruijie(config-if)# ip address 2001:1::1/64
Ruijie(config-if)# bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if)#exit
Ruijie(config)# ipv6 route static bfd GigabitEthernet 0/1 2001:1::2
Ruijie(config)# ipv6 route 2002::/64 GigabitEthernet 0/1 2001:1::2

```

**Related commands**      N/A

**Platform description**    This command is not supported on Layer 2 devices.

## 7.31 ipv6 static route-limit

Use this command to set the upper threshold of the static route. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 static route-limit** { *number* | **default-vrf** *number* | **vrf** *vrf-name number* }

**no ipv6 static route-limit** [ **default-vrf** ] | [ **vrf** *vrf-name* ]

**default ipv6 static route-limit** [ **default-vrf** ] | [ **vrf** *vrf-name* ]

| Parameter<br>Description | Parameter                         | Description                                                                             |
|--------------------------|-----------------------------------|-----------------------------------------------------------------------------------------|
|                          | <i>number</i>                     | Upper threshold of static routes in the range from 1 to 1,000,000.                      |
|                          | <b>default-vrf</b> <i>number</i>  | Upper threshold of static routes in the range from 1 to 10,000 in default VRF scenario. |
|                          | <b>vrf</b> <i>vrf-name number</i> | Upper threshold of static routes in the range from 1 to 10,000 in VRF scenario.         |

**Defaults**                The default is 1000.

**Command Mode**            Global configuration mode

**Usage Guide**            The goal is to control the number of static routes. You can view the upper threshold of the configured non-default static routes with the show running config command.

The following example sets the upper threshold of the global static routes to 900, the upper threshold of the global static routes to 200 in default VRF scenario, the upper threshold of the global static routes to 100 in VRF scenario and then restores the default value.

**Examples**

```

Ruijie(config)#ipv6 static route-limit ?
  <1-1000000> Global limit value(default value: 1024)
  default-vrf Default Routing/Forwarding instance
  vrf         VPN Routing/Forwarding instance

```

```
Ruijie(config)# ipv6 static route-limit 900
Ruijie(config)# ipv6 static route-limit default-vrf 200
Ruijie(config)# ipv6 static route-limit vrf test 100
Ruijie(config)# no ipv6 static route-limit
Ruijie(config)# no ipv6 static route-limit default-vrf
Ruijie(config)# no ipv6 static route-limit vrf test
```

**Related  
Commands**

| Command         | Description                       |
|-----------------|-----------------------------------|
| ipv6 route      | Configures the IPv6 static route. |
| show ipv6 route | Displays the IPv6 routing table.  |

**Platform**

**Description** This command is not supported on 2-layer devices.

## 7.32 ipv6 unicast-routing

Use this command to enable the IPv6 route function of the RGOS. Use the **no** form of this command to disable this function.

**ipv6 unicast-routing**

**no ipv6 unicast-routing**

**Parameter  
description**

None

**Default  
configuration**

This function is enabled by default.

**Command mode**

Global configuration mode

**Usage guidelines**

This function can be disabled if the device is just used as the bridge-connection device or the VOIP gateway device.

**Examples**

The example disables the IPv6 route function of RGOS.

```
Ruijie# no ipv6 unicast-routing
```

**Related commands**

| Command         | Description                     |
|-----------------|---------------------------------|
| ipv6 route      | Configure the IPv6 static route |
| show ipv6 route | Displays the IPv6 routing table |

**Platform description**

This command is not supported on Layer 2 devices.

## 7.33 maximum-paths

Use this command to specify the number of equivalent routes. Use the **no** form of this command is used to restore the default setting.

**maximum-paths** *number*

**no maximum-paths** *number*

| Parameter<br>description | Parameter     | Description                                                         |
|--------------------------|---------------|---------------------------------------------------------------------|
|                          | <i>number</i> | Number of equivalent routes in the range from 1 to device capacity. |

**Default configuration** The default value varies from products.

**Command mode**

Route map co

**Usage guidelines** With this command executed, the number of routes for load balancing is no more than the specified number of equivalent routes. You can view the number of equivalent routes with the show running config command.

**Examples** The following example sets the number of equivalent routes to 10 and then restores the default setting.

```
maximum-paths 10
no maximum-paths 10
```

## 7.34 maximum routes

Use this command to limit the number of routes in default VRF scenario. Use the **no** form of this command to restore the default setting.

**maximum routes** *limit* { *warn-threshold* | **warning-only** }

**no maximum routes**

| Parameter<br>Description | Parameter             | Description                                                                                                                                                      |
|--------------------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>limit</i>          | Indicates the limitation on number of routes. If the routes number exceeds the limitation, it will be written into the routing table.<br>Range: 1-4,294,967,295. |
|                          | <i>warn-threshold</i> | Indicates the threshold of printing alarm. Range: 1-100.                                                                                                         |
|                          | <b>warning-only</b>   | When the route reaches to the limited number, print log only.<br>(The route can still be written into the core routing table.)                                   |

**Defaults** N/A

**Command****Mode** Global configuration mode**Usage Guide**

The command is used to limit the routes running in default VRF scenario. If you want to obtain alarm only, please configure parameter **warning-only**.

**Examples**

The following example sets the maximum number of routes to 1,000 in default VRF scenario. An alarm log will be generated if the number exceeds 1,000.

```
Ruijie(config)# maximum routes 1000 100
```

## 7.35 show ip redirects

Use this command to display the default gateway IP address.

**show ip redirects**

Use this command to display the default gateway IP address.

**show ip redirects**

**Parameter****Description****Parameter**

N/A

**Description**

N/A

**Defaults**

N/A

**Command****Mode**

Privileged EXEC mode

**Usage Guide**

Use this command to display the default gateway IP address. This command is supported on 2-layer devices or 3-layer devices with the **no ip routing** command executed.

The following example displays the default gateway.

**Examples**

```
Ruijie# show ip redirects
Default Gateway: 192.168.195.1
```

**Field**

Default Gateway

**Description**

IP address of the default gateway.

**Related****Commands****Command**

N/A

**Description**

N/A

**Platform****Description**

This command is supported on 2-layer devices and 3-layer devices with the **no ip routing** command executed.

## 7.36 show ip route

Use the command to display the configuration of the IP routing table.

**show ip route** [ [ *vrf vrf\_name* ] [ *network* [ *mask* [**longer-prefix**] ] | **count** | *protocol* [ *process-id* ] | **weight** ] ]

**show ip route** [ *vrf vrf-name* ] [ [ **normal** | **ecmp** | **fast-reroute** ] [ *network* [ *mask* ] ]

### Parameter description

| Parameter            | Description                                                                                      |
|----------------------|--------------------------------------------------------------------------------------------------|
| <b>vrf vrf_name</b>  | (Optional) Displays the route information of the VRF.                                            |
| <i>network</i>       | (Optional) Displays the route information to the network.                                        |
| <i>mask</i>          | (Optional) Displays the route information to the network of this mask.                           |
| <b>longer-prefix</b> | (optional) Displays the routes that match the specified prefix.                                  |
| count                | (Optional) Displays the number of existent routes. (for the ECMP/WCMP route, displays one route) |
| <i>protocol</i>      | (Optional) Displays the route information of specific protocol.                                  |
| <i>process-id</i>    | (Optional) Routing protocol process ID.                                                          |
| weight               | (Optional) Displays the route information of non default weight.                                 |
| normal               | Displays normal routes and not equivalent routes or fast reroutes.                               |
| ecmp                 | Displays only equivalent routes.                                                                 |
| fast-reroute         | (Optional) Displays the master/standby route of fast reroute.                                    |

### Default

#### configuration

All routes are displayed by default.

### Command mode

Privileged EXEC mode/ global configuration mode/ interface configuration mode/ routing protocol configuration mode/ route map configuration mode.

### Usage guidelines

This command can display route information flexibly.

This command shows all routes. To show different attributes of routes, specify **normal** | **ecmp** | **fast-reroute**.

The following example displays the configuration of the IP routing table.

### Examples

```
Ruijie# show ip route

Codes: C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route

## 7.37 show ip route recursive

Use this command to display the IP route recursive information

**show ip route [ [ vrf vrf\_name ] recursive A.B.C.D/<0-32>**

| Parameter<br>Description | Parameter      | Description                                                                                |
|--------------------------|----------------|--------------------------------------------------------------------------------------------|
|                          | vrf vrf-name   | (Optional) Displays the route information of the specified VRF. The default is global VRF. |
|                          | A.B.C.D/<0-32> | Network address/mask                                                                       |

**Command Mode** Privileged EXEC mode

**Usage Guide** When the user checks the recursive information of an IP route, all reachable routes are displayed based on the longest match.

**Examples** The following displays the result of **show ip route recursive 50.1.1.1/32** command

```
Ruijie(config)# show ip route recursive 50.1.1.1/32
```

Codes: C - Connected, L - Local, S - Static

R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

E1 - OSPF external type 1, E2 - OSPF external type 2

SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2

IA - Inter area, EV - BGP EVPN, \* - candidate default

```
S    50.1.1.1/32 [1/0] via 50.1.3.2
```

```
O IA 50.1.1.0/24 [m] via 35.1.10.2, 00:38:26, VLAN 1
```

```
S*   0.0.0.0/0 is directly connected, Null 0
```

**Description**

## 7.38 show ip route static bfd

Use this command to display the IP route correlated BFD information

**show ip route** [ [ *vrf vrf\_name* ] **static bfd**

**Parameter  
description**

| Parameter           | Description                                                                               |
|---------------------|-------------------------------------------------------------------------------------------|
| <i>vrf vrf-name</i> | (Optional) Displays route information of the specified VRF.<br>The default is global VRF. |

**Default  
configuration**

N/A

**Command mode**

Privileged EXEC mode.

**Usage guidelines**

Use this command to display the IP route correlated BFD information

**Examples**

The following example displays the IP route correlated BFD information,

```
Ruijie(config)#show ip route static bfd
S      10.0.0.0/8 via 100.100.100.25, GigabitEthernet 0/3, BFD state is
Up
S      20.0.0.0/8 via 200.100.100.25, GigabitEthernet 0/4, BFD state is
Admin
```

| Field     | Description                               |
|-----------|-------------------------------------------|
| S         | Static route                              |
| BFD state | State of the static route correlated BFD. |

**Related commands**

N/A

**Platform description**

This command is not supported on Layer 2 devices.

## 7.39 show ip route summary

Use this command to display the statistical information about one routing table.

**show ip route** [*vrf vrf\_name*] **summary**

Use this command to display the statistical information about all routing tables.

**show ip route summary all**

**Parameter  
Description**

| Parameter       | Description |
|-----------------|-------------|
| <i>vrf-name</i> | VRF name    |

**Defaults**

N/A

**Command**

**Mode** Privileged EXEC mode

**Usage**

**guideline** N/A

The following example displays the statistics of the global routing table.

```
Ruijie# show ip route summary
```

Codes: NORMAL - Normal route ECMP - ECMP route FRR - Fast-Reroute route

Memory: 2000 bytes

Entries: 22 , based on route prefixes

Entries: 29 , based on route nexthops

|           | NORMAL | ECMP | FRR | TOTAL |
|-----------|--------|------|-----|-------|
| Connected | 3      | 0    | 0   | 3     |
| Static    | 2      | 1    | 1   | 4     |
| RIP       | 1      | 2    | 1   | 4     |
| OSPF      | 2      | 1    | 1   | 4     |
| ISIS      | 1      | 2    | 0   | 3     |
| BGP       | 2      | 1    | 1   | 4     |
| TOTAL     | 11     | 7    | 4   | 22    |

The following example displays the statistics of all routing tables.

```
Ruijie# show ip route summary all
```

Codes: NORMAL - Normal route ECMP - ECMP route FRR - Fast-Reroute route

IP routing table count:2

Total

Memory: 4000 bytes

Entries: 44 , based on route prefixes

Entries: 44 , based on route nexthops

|           | NORMAL | ECMP | FRR | TOTAL |
|-----------|--------|------|-----|-------|
| Connected | 6      | 0    | 0   | 6     |
| Static    | 4      | 2    | 2   | 8     |
| RIP       | 2      | 4    | 2   | 8     |
| OSPF      | 4      | 2    | 2   | 8     |
| ISIS      | 2      | 4    | 0   | 6     |

## 7.40 show ip route track-table

Use this command to display the IP route correlated Track information.

**show ip route [ [ vrf vrf\_name ] track-table**

| Parameter    | Parameter                                                                                                                            | Description                                                                                     |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Description  | vrf vrf_name                                                                                                                         | (Optional) Displays the route information of the specified VRF name. The default is global VRF, |
| Defaults     | N/A                                                                                                                                  |                                                                                                 |
| Command Mode | Privileged EXEC mode                                                                                                                 |                                                                                                 |
| Usage Guide  | Use this command to display the IP route correlated Track information.                                                               |                                                                                                 |
| Examples     | <p>The following example displays the IP route correlated Track information.</p> <pre>Ruijie(config)#show ip route track-table</pre> |                                                                                                 |

```
ip route 10.0.0.0 255.0.0.0 GigabitEthernet 0/0 track 2 state is [up]
ip route 20.0.0.0 255.0.0.0 GigabitEthernet 0/0 2 track 3 state is [down]
:
```

| Field | Description        |
|-------|--------------------|
| track | Track target index |
| state | Track target state |

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform**

**Description** This command is not supported on 2-layer devices.

## 7.41 show ipv6 redirects

Use this command to display the IPv6 default gateway IP address.

**show ipv6 redirects**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

The following example displays the default gateway IPv6 address.

```
Ruijie# show ipv6 redirects
Default Gateway: 10::1
```

**Examples**

| Field           | Description                         |
|-----------------|-------------------------------------|
| Default Gateway | IPv6 address of the default gateway |

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** This command is supported on 2-layer devices and 3-layer devices with the **no ip routing** command executed..

## 7.42 show ipv6 route

Use the command to display the configuration of the IPv6 routing table.

**show ipv6 route** [ *vrf vrf-name*] [ [ *network / prefix-length*] | **summary** | *protocol* | **weight**]

### Parameter description

| Parameter       | Description                                                                 |
|-----------------|-----------------------------------------------------------------------------|
| <i>network</i>  | (Optional) Displays the route information to the network.                   |
| <i>vrf-name</i> | VRF name.                                                                   |
| <b>summary</b>  | (Optional) Displays the classified statistics of the number of ipv6 routes. |
| <i>protocol</i> | ((Optional) Displays the route information of specific protocol.            |
| <b>weight</b>   | (Optional) Displays the non-default-weight routes only.                     |

### Default configuration

All routes are displayed by default.

### Command mode

Privileged EXEC mode/ global configuration mode, interface configuration mode/ routing protocol configuration mode/ route map configuration mode.

### Usage guidelines

Use this command to display route information flexibly.

### Examples

The following example displays the output of this command.

```
Ruijie(config)# show ipv6 route

IPv6 routing table - Default - 7 entries
Codes: C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type
2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area

C    10::/64 via Loopback 1, directly connected
L    10::1/128 via Loopback 1, local host
S    20::/64 [20/0] via 10::4, Loopback 1C
C    FE80::/10 via Null 0, directly connected
C    FE80::/64 via Loopback 1, directly connected
L    FE80::2D0:F8FF:FE22:33AB/128 via Loopback 1, local host
```

| Field | Description |
|-------|-------------|
|-------|-------------|

|         |                                                                                                                                                                                                                                                                                                                   |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| O       | Source routing protocol, which may be:<br>C: directly connected route<br>S: static route<br>R: RIP route<br>B: BGP route<br>O: OSPF route<br>I: IS-IS route                                                                                                                                                       |
| E2      | Route type, which may be:<br>E1: OSPF external route type 1<br>E2: OSPF external route type 2<br>N1: OSPF NSSA external type 1<br>N2: OSPF NSSA external type 2<br>IA: OSPF area internal route<br>SU: IS-IS summary route<br>L1: IS-IS level-1 route<br>L2: IS-IS level-2 route<br>IA: IS-IS area internal route |
| 20::/64 | Network address and mask of the destination network                                                                                                                                                                                                                                                               |
| [20/0]  | Administrative distance/metric                                                                                                                                                                                                                                                                                    |

**Related commands**

| Command           | Description                       |
|-------------------|-----------------------------------|
| <b>ipv6 route</b> | Configures the IPv6 static route. |

**Platform description**

This command is not supported on Layer 2 devices.

## 7.43 show ip route static bfd

Use this command to display the IPv6 route correlated BFD information

**show ipv6 route [ [ vrf *vrf\_name* ] static bfd**

**Parameter  
description**

| Parameter                  | Description                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>vrf <i>vrf-name</i></b> | (Optional) Displays the route information of the designated VRF name of the static route. The default is global VRF, |

**Default  
configuration**

N/A

**Command mode**

Privileged EXEC mode.

**Usage guidelines**

Use this command to display the IPv6 route correlated BFD information.

The following example displays the IPv6 route correlated BFD information.

```
Ruijie(config)#show ip route static bfd
S    25::/64 via 100::25, GigabitEthernet 0/3, BFD state is Up
S    26::/64 via 200::25, GigabitEthernet 0/4, BFD state is Admin
```

#### Examples

| Field     | Description                              |
|-----------|------------------------------------------|
| S         | Static route                             |
| BFD state | State of the static route associated BFD |

**Related commands** N/A

**Platform description** This command is not supported on Layer 2 devices.

## 7.44 show ipv6 route summary

Use this command to display the statistics of the IPv6 routing table of a specified VRF.

**show ipv6 route [ vrf vrf-name ] summary**

Use this command to display statistics of all IPv6 routing tables.

**show ipv6 route summary all**

#### Parameter description

| Parameter       | Description                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | (Optional) VRF name. If no VRF name is specified, statistics of the IPv6 routing table of the global VRF are displayed. |

#### Default

**configuration** N/A

**Command mode** Privileged EXEC mode.

**Usage guidelines** N/A

The following example displays statistics of IPv6 routing table of the global VRF.

```
Ruijie#show ipv6 route summary
IPv6 routing table name is - Default(0) global scope - 5 entries
IPv6 routing table default maximum-paths is 32
Local          2
Connected      3
Static         0
PIP            0
OSPF           0
BGP            0
-----
Total          5
```

#### Examples

The following example displays the statistics of all IPv6 routing tables.

```
Ruijie#show ipv6 route summary
IPv6 routing table name is - Default(0) global scope - 5 entries
IPv6 routing table default maximum-paths is 32
Local          2
Connected      3
Static         0
PIP            0
OSPF           0
BGP            0
-----
Total          5
```

| Field                    | Description                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Memory                   | The memory size occupied by the current routing table.                                                                                                                                                                                                                                  |
| Entries                  | The entries in the current routing table (based on the entry prefix instead of the next hop entry.)                                                                                                                                                                                     |
| Connected                | Describes the protocol type of the entry. The field can be:<br>Connected: Connected route entry.<br>Static: Static route entry.<br>RIP: RIP route entry.<br>OSPF: OSPF route entry.<br>ISIS: ISIS route entry.<br>BGP: BGP route entry.<br>TOTAL: Total number of all protocol entries. |
| IPv6 routing table count | The number of the routing tables.                                                                                                                                                                                                                                                       |
| Global                   | The name of the current routing table. The field can be:<br>Global : Global (The default VRF)<br>VRF1: VRF name.<br>TOTAL: All VRF routing table summary.                                                                                                                               |

## 8 Protocol-independent Configuration Commands

### 8.1 accept-lifetime

Use this command in the encryption key configuration mode to specify the lifetime of an encryption key in its receiving direction. Use the no form of this command to restore the default value.

**accept-lifetime** *start-time* {**infinite** | *end-time* | **duration** *seconds*}

**no accept-lifetime**

| Parameter   | Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| description | <i>start-time</i>              | Start time of the lifetime. The syntax is as follows:<br><i>hh:mm:ss month date year</i><br><i>hh:mm:ss date month year</i> <ul style="list-style-type: none"> <li>● hh—hour</li> <li>● mm—minute</li> <li>● ss—second</li> <li>● month—month</li> <li>● date—day</li> <li>● year—year</li> </ul> The default start time is Jun 1, 1993, which is also the earliest start time available. |
|             | <b>infinite</b>                | Indicates that the encryption key is valid for ever.                                                                                                                                                                                                                                                                                                                                      |
|             | <i>end-time</i>                | <i>End time of the encryption key. It must be later than the start time.</i>                                                                                                                                                                                                                                                                                                              |
|             | <b>duration</b> <i>seconds</i> | Duration of the encryption key after the start time. The value ranges from 1 to 2147483646.                                                                                                                                                                                                                                                                                               |
|             |                                |                                                                                                                                                                                                                                                                                                                                                                                           |

**Default**      infinite

**Command mode**      Encryption key configuration mode

**Usage guideline**      Use this command to specify the lifetime of an encryption key in its receiving direction.

**Examples**      The following example configures the lifetime from 0:00 on September 9, 2000 to 0:00 on October 12, 2011.

```
Ruijie(config)# key chain ripkeys
```

```
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)#accept-lifetime 00:00:00 Sep 9 2000 00:00:00 Dec
12 2011
```

## 8.2 ip as-path access-list

Use this command to configure an autonomous system (AS) path filter using a regular expression. Use the **no** form of this command to remove the AS path filter using a regular expression.

**ip as-path access-list** *path-list-num* { **permit** | **deny** } *regular-expression*

**no ip as-path access-list** *path-list-num* [ { **permit** | **deny** } *regular-expression* ]

| Parameter<br>description | Parameter                 | Description                                                                                                  |
|--------------------------|---------------------------|--------------------------------------------------------------------------------------------------------------|
|                          | <i>path-list-num</i>      | Specifies the AS-path access-list number. The range is from 1 to 500.                                        |
|                          | <b>permit</b>             | Permits advertisement based on matching conditions.                                                          |
|                          | <b>deny</b>               | Denies advertisement based on matching conditions.                                                           |
|                          | <i>regular-expression</i> | Regular expression that defines the AS-path filter. The expression length range is from 1 to 255 characters. |

**Default** By default, no AS path filter using a regular expression is configured.

**Command mode** Global configuration mode

**Usage guideline** N/A

**Examples** The following example configures an AS path filter matching the path which contains AS number 123 only.

```
Ruijie(config)# ip as-path access-list 105 deny ^123$
```

## 8.3 ip community-list

Use this command to define a standard or expanded community list and control access to it. Use the **no** form of this command to remove the setting.

```
ip community-list { community-list-number | standard community-list-name } { permit | deny }
[ { community-list-number | internet | local-AS | no-advertise | no-export | gshut } ]
ip community-list { community-list-number | expanded community-list-name } { permit | deny }
[ regular-expression ]
```

description**

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>community-list-name</i> | Name of the community list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| standard                   | Indicates standard community list numbered in 1 to 99.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| expanded                   | Indicates expanded community list numbered in 100 to 199.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| permit                     | Permits access to the community list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| deny                       | Denies access to the community list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>community-number</i>    | Community number in the form of AA:NN(AS number/2-byte numerical) in the range of 1 to 255 characters. It may also be one of the following value:<br>Internet: Indicates the Internet community. All paths belong to this community.<br>no-export: Indicates that this path will not be advertised to any EBGp peers.<br>no-advertise: Indicates that this path will not be advertised to any BGP peers.<br>local-as: Indicates that this path will not be advertised to out of the AS. When AS confederation is configured, this path will not be advertised to other ASs or sub-ASs. |
| <b>gshut</b>               | Indicates the route is advertised by a gracefully shutdown neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Default  
configuration** None

**Command** Global configuration mode.

**mode****Usage**

**guidelines** This command is used to define the community list for BGP.

**Examples**

```
Ruijie(config)# ip community-list standard 1 deny 100.20.200.20
Ruijie(config)# ip community-list standard 1 permit internet
```

| Related<br>commands | Command                   | Description                                                                 |
|---------------------|---------------------------|-----------------------------------------------------------------------------|
|                     | match community           | Match the community list.                                                   |
|                     | set community-list delete | Remove the community value of the BGP path according to the community list. |
|                     | show ip community-list    | Show the community list information.                                        |

## 8.4 ip extcommunity-list

Use this command to create an extcommunity list and add an entry to the list. Use the **no** form of this command to remove the setting.

**ip extcommunity-list** {*expanded-list* | **expanded** *list-name*} {**permit** | **deny**} [*regular-expression*]

**ip extcommunity-list** {*standard-list* | **standard** *list-name*} {**permit** | **deny**} [*rt value*] [*soo value*]

**no ip extcommunity-list** {*expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name*}

Use this command to create an extcommunity list and enter ip extcommunity-list configuration mode.

Use the **no** form of this command to remove the setting.

**ip extcommunity-list** {*expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name*}

**no ip extcommunity-list** {*expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name*}

|--------------------------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>expand-list</i>               | Indicates an extended extcommunity list, ranging from 100 to 199. One extcommunity list may contain multiple rules.                                                        |
|                          | <i>standard-list</i>             | Indicates a standard extcommunity list, ranging from 1 to 99. One extcommunity list may contain multiple rules.                                                            |
|                          | <b>expanded</b> <i>list-name</i> | Indicates the name of an extended extcommunity, comprising not more than 32 characters. When using this parameter, you enter the extcommunity list configuration mode.     |
|                          | <b>standard</b> <i>list-name</i> | Indicates the name of a standard extcommunity list, comprising not more than 32 characters. When using this parameter, you enter the extcommunity list configuration mode. |
|                          | <b>permit</b>                    | Defines an extcommunity rule for permitting.                                                                                                                               |
|                          | <b>deny</b>                      | Defines an extcommunity rule for denying.                                                                                                                                  |

|                           |                                                                                                                                                                                                                                     |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>regular-expression</i> | (optional) Defines a matching template that is used to match an extcommunity.                                                                                                                                                       |
| <i>sequence-number</i>    | (Optional) Defines the sequence number of a rule, ranging from 1 to 2,147,483,647. If no sequence number is specified, the sequence number automatically increases by 10 when a rule is added by default. The initial number is 10. |
| <b>rt</b>                 | (Optional) Sets the RT attribute value. This command can be used only for the standard extcommunity configuration, but not for the extended extcommunity configuration.                                                             |
| <b>soo</b>                | (Optional) Sets the SOO attribute value. This command can be used only for the standard extcommunity configuration, but not for the extended extcommunity configuration.                                                            |
| <i>value</i>              | Indicates the value of an extended community (extend_community_value).                                                                                                                                                              |

**Default** It is disabled by default.

**Command mode** Global configuration mode and ip extcommunity-list configuration mode.

**Usage guidelines** This command is used to define the extcommunity list.

1.The following example defines an ip extcommunity-list.

```
Ruijie(config)# ip extcommunity-list 1 permit rt 100:1
Ruijie(config)# ip extcommunity-list standard aaa permit rt
100:2
Ruijie(config)# ip extcommunity-list expanded ext1 permit 200:[0~9][0~9]
```

**Examples** 2. The following example displays how to use ip extcommunity.

```
Ruijie(config)# route-map rt_in_filter
Ruijie(config-route-map)# match extcommunity 1
Ruijie(config-route-map)# match extcommunity ext1
Ruijie(config)# router bgp 100
Ruijie(config-router)# address-family vpn
Ruijie(config-router-af)#neighbor 3.3.3.3 send-community extended
Ruijie(config-router-af)#neighbor 3.3.3.3 route-map rt_in_filter in
```

## 8.5 ip prefix-list

Use this command to create a prefix list or add an entry to the prefix list. Use the **no** form of this command to remove the prefix list or an entry.

**ip prefix-list** *prefix-list-name* [ **seq** *seq-number* ] { **deny** | **permit** } *ip-prefix* [**ge** *minimum-prefix-length*][ **le** *maximum-prefix-length*]

**no ip prefix-list** *prefix-list-name* [ **seq** *seq-number* ] { **deny** | **permit** } *ip-prefix* [**ge** *minimum-prefix-length*][ **le** *maximum-prefix-length*]

### Parameter description

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>prefix-list-name</i>      | Name of the prefix list                                                                                                                                                                                                                                                                                                                                                                               |
| <i>seq-number</i>            | Sequence number of an entry in the range of 1 to 2147483647. When you execute this command to add an entry without a sequence number, the system allocates a default sequence number for the entry. The default sequence number of the first entry is 5. Every subsequent entry without a sequence number uses the time of 5 larger than the previous sequence number as the default sequence number. |
| <b>deny</b>                  | Deny the route matching the prefix list.                                                                                                                                                                                                                                                                                                                                                              |
| <b>permit</b>                | Permit the route matching the prefix list.                                                                                                                                                                                                                                                                                                                                                            |
| <i>ip-prefix</i>             | Network address and mask. Network address can be any valid IP address and the mask length is in the range of 0 to 32.                                                                                                                                                                                                                                                                                 |
| <i>minimum-prefix-length</i> | (Optional) Minimum length of the prefix (the starting length)<br>Note: “ge” indicates the operation of “larger than” and “equivalent to”.                                                                                                                                                                                                                                                             |
| <i>maximum-prefix-length</i> | (Optional) Maximum length of the prefix (the ending length)<br>Note: “le” indicates the operation of “less than” and “equivalent to”.                                                                                                                                                                                                                                                                 |

### Default configuration

None

### Command mode

Global configuration mode.

### Usage guidelines

The ip prefix-list command configures the prefix list, with the permit or deny keyword to determine the action in case of matching.

You can execute this command to define an exact match, or use “ge” or “le” to define a range match for a prefix for flexible configuration. “ge” indicates the range of

minimum-prefix-length to 32; “le” indicates the range of the mask length of the IP prefix to maximum-prefix-length; “ge” and “le” indicates the range of minimum-prefix-length to maximum-prefix-length, namely, mask length of IP prefix < minimum-prefix-length < maximum-prefix-length <=32.

The following example filters the RIP routes the OSPF redistributes by the destination IP address following the rule defined in the associated IP prefix list, for example, redistribute the routes whose destination IP address is in the range 201.1.1.0/24.

#### Examples

```
Ruijie# configure terminal
Ruijie(config)# ip prefix-list pre1 permit 201.1.1.0/24
Ruijie(config)# router ospf
Ruijie(config-router)# distribute-list prefix pre1 out rip
Ruijie(config-router)# end
```

## 8.6 ip prefix-list description

Use this command to add the description of a prefix list. Use the **no** form of this command to delete the description.

**ip prefix-list** *prefix-list-name* **description** *description-text*

| Parameter                    | Parameter                                              | Description                    |
|------------------------------|--------------------------------------------------------|--------------------------------|
|                              | description                                            |                                |
|                              | <i>prefix-list-name</i>                                | Name of the prefix list        |
|                              | <i>description-text</i>                                | Description of the prefix list |
| <b>Default configuration</b> | No description is added for a prefix list, by default. |                                |
| <b>Command mode</b>          | Global configuration mode                              |                                |

#### Examples

The example below adds the description for the prefix list:

```
Ruijie# configure terminal
Ruijie(config)# ip prefix-list pre description Deny routes from Net-A
```

## 8.7 ip prefix-list sequence-number

Use this command to enable sort function for a prefix list. Use the **no** form of this command to disable the sort function.

**ip prefix-list** **sequence-number**

**Parameter description** Disabled

**Default configuration** No sequence number is added for a prefix list, by default.

**Command mode** Global configuration mode

**Examples** The example below adds a sequence number for the prefix list:

```
Ruijie# configure terminal
Ruijie(config)# ip prefix-list pre description deny routes from Net-A
```

| Related commands | Command        | Description                |
|------------------|----------------|----------------------------|
|                  | ip prefix-list | Configure the prefix list. |

**Platform description** N/A

## 8.8 ipv6 prefix-list

Use this command to create an IPv6 prefix list or add an entry in the prefix list. Use the **no** form of this command to delete an IPv6 prefix list or an entry in the prefix list.

**ipv6 prefix-list** *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv6-prefix* [**ge** *minimum-prefix-length*][**le** *maximum-prefix-length*]

**no ipv6 prefix-list** *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv6-prefix* [**ge** *minimum-prefix-length*][**le** *maximum-prefix-length*]

**Parameter description**

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>prefix-list-name</i>      | Name of the prefix list                                                                                                                                                                                                                                                                                                                                      |
| <i>seq-number</i>            | Sequence number of an entry in the prefix list. Its range is 1 to 4294967294. If the sequence number is not specified in this command, the system will allocate a default one for the entry. The default sequence number of the first entry is 5, and that of each subsequent one is the product of adding 5 to the sequence number of the proceeding entry. |
| <b>permit</b>                | Permit the access to the matching result.                                                                                                                                                                                                                                                                                                                    |
| <b>deny</b>                  | Deny the access to the matching result.                                                                                                                                                                                                                                                                                                                      |
| <i>ipv6-prefix</i>           | Network address and its mask. The network address can be any valid IP address. The mask can be 0 to 32 characters.                                                                                                                                                                                                                                           |
| <i>minimum-prefix-length</i> | (Optional) Minimum length of the prefix (the starting length)<br>Note: “ge” indicates the operation of “larger than” and “equivalent to”.                                                                                                                                                                                                                    |
| <i>maximum-prefix-length</i> | (Optional) Maximum length of the prefix (the ending length)<br>Note: “le” indicates the operation of “less than” and “equivalent to”.                                                                                                                                                                                                                        |

**Default configuration**

No prefix list is created.

**Command mode**

Global configuration mode

**Usage guideline**

The ipv6 prefix-list command configures the prefix list, with the permit or deny keyword to determine the action in case of matching.

You can execute this command to define an exact match, or use “ge” or “le” to define a range match for a prefix for flexible configuration. “ge” indicates the range of minimum-prefix-length to 128; “le” indicates the range of the mask length of the IP prefix to maximum-prefix-length; “ge” and “le” indicates the range of minimum-prefix-length to maximum-prefix-length, namely, ipv6-prefix mask length < minimum-prefix-length < maximum-prefix-length <= 128

**Examples**

The following example filters the RIP routes the OSPF redistributes by the destination IP address following the rule defined in the associated IP prefix list, for example, redistribute the routes whose destination IP address is in the range 2222::/64.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 prefix-list pre1 permit 2222::/64
Ruijie(config)# ipv6 router ospf
Ruijie(config-router)# distribute-list prefix pre out rip
Ruijie(config-router)# end
```

## 8.9 ipv6 prefix-list description

Use this command to add the description of an IPv6 prefix list. Use the **no** form of this command to delete the description.

**ipv6 prefix-list** *prefix-lis-name* **description** *description-text*

**no ipv6 prefix-list** *prefix-lis-name* **description** *description-text*

| Parameter | Parameter               | Description                         |
|-----------|-------------------------|-------------------------------------|
|           | <i>prefix-lis-name</i>  | Name of the ipv6 prefix list        |
|           | <i>description-text</i> | Description of the ipv6 prefix list |

### Default

**configuration** No description is added for an IPv6 prefix list, by default.

**Command mode** Global configuration mode

### Examples

The example below adds the description for the prefix list:

```
Ruijie# configure terminal
Ruijie(config)# ipv6 prefix-list pre description Deny routes from Net-A
```

| Related commands | Command          | Description                     |
|------------------|------------------|---------------------------------|
|                  | ipv6 prefix-list | Configure the IPv6 prefix list. |

## 8.10 ipv6 prefix-list sequence-number

Use this command to enable the sorting function for an IPv6 prefix list. Use the **no** form of this command to remove the settings.

**ipv6 prefix-list sequence-number**

**no ipv6 prefix-list sequence-number**

**Parameter**  
**description** Disabled.

### Default

**configuration** No sequence number is added for a prefix list, by default.

**Command mode** Global configuration mode

**Examples** The example below adds a sequence number for the prefix list:

```
Ruijie# configure terminal
Ruijie(config)# ipv6 prefix-list pre description Deny routes from Net-A
```

Related commands

|------------------|---------------------------------|
| ipv6 prefix-list | Configure the IPv6 prefix list. |

## 8.11 key

Use this command to define an encryption key and enter the encryption key chain configuration mode.

Use the no form of this command to delete it.

**key** *key-id*

**no key** *key-id*

| Parameter   | Parameter     | Description                           |
|-------------|---------------|---------------------------------------|
| description | <i>key-id</i> | Key ID, ranging from 0 to 2147483647. |

Default No encryption key is configured.

Command mode Encryption key chain configuration mode.

Usage guideline Use this command to define an encryption key.

Examples The following example configures encryption key chain ripkeys and key 1.

```
Ruijie(config)# key chain ripkeys
Ruijie(config-keychain)# key 1
```

## 8.12 key chain

Use this command to define a key chain and enter the key chain configuration mode. Use the no form of this command to delete it.

**key chain** *key-chain-name*

**no key chain** *key-chain-name*

| <b>Parameter description</b> | Parameter                                                                                                                                                 | Description     |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
|                              | <i>key-chain-name</i>                                                                                                                                     | Key chain name. |
| <b>Default</b>               | No key chain is configured.                                                                                                                               |                 |
| <b>Command mode</b>          | Global configuration mode.                                                                                                                                |                 |
| <b>Usage guideline</b>       |  For a key chain to take effect, you need to configure at least one key. |                 |
| <b>Examples</b>              | The following example configures key chain ripkeys and enters the key chain configuration mode.<br><pre>Ruijie(config)# key chain ripkeys</pre>           |                 |
| <b>Related command</b>       | Command                                                                                                                                                   | Description     |

| <b>Platform description</b>  | -                                                                                                                                                         |                 |

## 8.13 key-string

Use this command to specify a key string. Use the no form of this command to delete it.

**key-string** [0|7] *text*

**no key-string**

| <b>Parameter description</b> | Parameter                                 | Description            |
|------------------------------|-------------------------------------------|------------------------|
|                              | <b>0</b>                                  | Use plaintext.         |
|                              | <b>7</b>                                  | Use encryption.        |
|                              | <i>text</i>                               | Authentication string. |
| <b>Default</b>               | No key string is configured.              |                        |
| <b>Command mode</b>          | Encryption key configuration mode.        |                        |
| <b>Usage guideline</b>       | Use this command to specify a key string. |                        |

**Examples** The following example configures key chain ripkeys, key 1 and the key string abc:

```
Ruijie(config)# key chain ripkeys
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)#key-string abc
```

## 8.14 match as-path

Use this command to redistribute the routes of AS\_PATH attribute permitted by the access list in the route map configuration mode. Use the **no** form of this command to remove the setting.

**match as-path** *as-path-acl-list-num* [*as-path-acl-list-num.....*]

**no match as-path** *as-path-acl-list-num* [*as-path-acl-list-num.....*]

**Parameter  
description**

| Parameter                   | Description                           |
|-----------------------------|---------------------------------------|
| <i>as-path-acl-list-num</i> | ACL number, in the range of 1 to 500. |
| <i>access-list-name</i>     | Name of the access list               |

**Default  
configuration** None.

**Command  
mode** Route map configuration mode.

**Usage  
guidelines** The match as-path can be followed by an access list number or name.  
One or more match or set commands can be executed to configure one route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

**Examples**

```
!  
route-map ROUTEMAP2IBGP  
match as-path 20 30
```

**Related  
commands**

| Command                | Description          |
|------------------------|----------------------|
| <b>match community</b> | Match the community. |

|                            |                                                   |
|----------------------------|---------------------------------------------------|
| <b>match metric</b>        | Match the metric.                                 |
| <b>match origin</b>        | Match the source of routes.                       |
| <b>set as-path prepend</b> | Set the AS_PATH attribute of redistributed routes |
| <b>set metric</b>          | Set the metric.                                   |
| <b>set metric-type</b>     | Set the metric type.                              |

## 8.15 match community

Use this command to redistribute the routes matching the Community attribute permitted by the ACL in the route map configuration mode. Use the **no** form of this command to remove the setting.

**match community** { *community-list-number* | *community-list-name* } [**exact-match**] [ { *community-list-number* | *community-list-name* } [**exact-match**] ...]

**no match community** { *community-list-number* | *community-list-name* } [**exact-match**] [ { *community-list-number* | *community-list-name* } [**exact-match**] ...]

| Parameter description | Parameter                    | Description                                                                                                                     |
|-----------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>community-list-number</i> | Number of the standard community list in the range 1 to 99.<br>Number of the extended community list in the range of 100 to 199 |
|                       | <i>communitys-list-name</i>  | Name of the community list in the range of less than 80 characters                                                              |
|                       | <b>exact-match</b>           | Match the community list exactly.                                                                                               |

**Default configuration**      None.

**Command mode**      Route map configuration mode.

**Usage guidelines**      The match community can be followed by more than one community list number or name, but the total of community lists and names should not be greater than 6.

Each exact-match applies to only the previous list, not all the lists.

One or more match or set commands can be executed to configure one route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

### Examples

```
ip community-list 1 permit 100:2 100:30
route-map set lopref
match community 1 exact-match
set local-preference 20
```

## 8.16 match extcommunity

Use this command to define the match rule for the BGP extcommunity. Use the no form of this command to cancel the setting.

**match extcommunity** { *standard-list-number* | *standard-list-name* | *expanded-list-num* | *expanded-list-name* }

**no match extcommunity** { *standard-list-number* | *standard-list-name* | *expanded-list-num* | *expanded-list-name* }

### Parameter description

| Parameter                          | Description                                                                                                                   |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b><i>standard-list-number</i></b> | Standard extcommunity list number, ranging from 1 to 99.<br>An extcommunity list may contains multiple excommunity values.    |
| <b><i>standard-list-name</i></b>   | Standard excommunity name.<br>An extcommunity list may contains multiple excommunity values.                                  |
| <b><i>expanded-list-num</i></b>    | Expanded extcommunity list number, ranging from 100 to 199.<br>An extcommunity list may contains multiple excommunity values. |
| <b><i>expanded-list-name</i></b>   | Expanded excommunity name.<br>An extcommunity list may contains multiple excommunity values.                                  |

## Default

The rule is not defined in the associated route map.

## Command mode

Route map configuration mode.

## Usage guideline

There are the following scenarios for a route map with an extcommunity:

1. The route map associated with **import map** uses the RT attribute to filter imported VRF routes.
2. The route maps associated with **neighbor route-map in** and **neighbor route-map out** are configured in the BGP VPNv4 address family mode and use the RT attribute to filter VPNv4 routes sent to or by BGP peers.

## Examples

1. Define two extcommunity:

```
Ruijie(config)# ip extcommunity-list 1 permit rt 100: 1
Ruijie(config)# ip extcommunity-list 1 permit rt 100: 2
```

## 2. Define match rules in the route map:

```
Ruijie(config)# route-map rt
Ruijie(config-route-map)# match extcommunity 1
```

## 3. Use the route map.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 3.3.3.3 route-map rt in
```

## Related command

| <b>ip extcommunity-list</b>      | Create an extcommunity list. |
| <b>show ip extcommunity-list</b> | Show an extcommunity list.   |

## Platform description -

## 8.17 match interface

Use **match interface** command to redistribute the routes whose next hop is the specified interface. Use the **no** form of this command to remove the setting.

**match interface** *interface-type interface-number* [...*interface-type interface-number*]

**no match interface** [*interface-type interface-number* [...*interface-type interface-number*]]

## Parameter description

| Parameter               | Description      |
|-------------------------|------------------|
| <i>interface-type</i>   | Interface type   |
| <i>interface-number</i> | Interface number |

## Default configuration

None.

## Command mode

Route map configuration mode.

## Usage guidelines

This command can be followed by multiple interfaces.

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used,

no operation will be performed.

The route map can be configured very flexibly for route redistribution and policy-based routing. No matter how the route map is used, the configuration principle is the same, except that different command sets are used. Even if it is used on the route redistribution, different routing protocols can use different commands with the route map.

The following example redistributes the RIP route with the next hop of fastethernet 0/0 in the OSPF routing protocol.

#### Examples

```
router ospf
 redistribute rip subnets route-map redrip
 network 192.168.12.0 0.0.0.255 area 0

route-map redrip permit 10
 match interface fastethernet 0/0
```

#### Related commands

| <b>set metric</b>            | Set the metric.                                   |
| <b>set metric-type</b>       | Set the metric type.                              |
| <b>set tag</b>               | Set the tag.                                      |

## 8.18 match ip address

Use **match ip address** command to redistribute the routes matching the IP address permitted by the ACL or the prefix list.

Use the **no** form of this command to remove the setting.

**match ip address** {*access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*] }

**no match ip address** [*access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*] ]

#### Parameter description

| Parameter                                  | Description                       |
|--------------------------------------------|-----------------------------------|
| <i>access-list-number</i>                  | Number of the access list         |
| <i>access-list-name</i>                    | Name of the access list           |
| <b>prefix-list</b> <i>prefix-list-name</i> | Specify the prefix list to match. |

**Default**

**configuration** None.

**Command mode**

Route map configuration mode.

Multiple access list numbers or names may follow match ip address.

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

**Usage guidelines**

The route map can be configured very flexibly for route redistribution and policy-based routing. No matter how the route map is used, the configuration principle is the same, except that different command sets are used. Even if it is used on the route redistribution, different routing protocols can use different commands with the route map.

By default, all lists are deleted if no list number is entered.

In some versions, match ip address allow ACL and ip prefix to co-exist to support the separation of odd/even routes. Match ip address associates with ACL to filter the odd/even routes, and associates with prefix list to filter the subnet mask length, so as to separate routes with the specific subnet mask length according to parity.

The following example enables the OSPF routing protocol to redistribute RIP routes that match access list 10, with the route type being type-1 external type and the default metric being 40.

```
router ospf
redistribute rip subnets route-map redrip
network 192.168.12.0 0.0.0.255 area 0

access-list 10 permit 200.168.23.0

route-map redrip permit 10
match ip address 10
set metric 40
set metric-type type-1!
```

**Examples****Related  
commands**

| Command            | Description          |
|--------------------|----------------------|
| <b>access-list</b> | Set the access list. |

|                              |                                                    |
|------------------------------|----------------------------------------------------|
| <b>match interface</b>       | Match the next-hop interface of the route.         |
| <b>match ip next-hop</b>     | Match the next-hop address in the access list.     |
| <b>match ip route-source</b> | Match the route source address in the access list. |
| <b>match metric</b>          | Match the metric.                                  |
| <b>match route-type</b>      | Match the route type.                              |
| <b>match tag</b>             | Match the tag.                                     |
| <b>set metric</b>            | Set the metric.                                    |
| <b>set metric-type</b>       | Set the metric type.                               |
| <b>set tag</b>               | Set the tag.                                       |

## 8.19 match ip next-hop

Use **match ip next-hop** command to redistribute the routes whose next-hop IP address matches the access list or the prefix list. Use the **no** form of this command to remove the setting.

**match ip next-hop** {*access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*] }

**no match ip next-hop** [*access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*] ]

| Parameter description | Parameter                                     | Description                       |
|-----------------------|-----------------------------------------------|-----------------------------------|
|                       | <i>access-list-number</i>                     | Number of the access list         |
|                       | <i>access-list-name</i>                       | Name of the access list           |
|                       | <b>prefix-list</b><br><i>prefix-list-name</i> | Specify the prefix list to match. |

**Default configuration** None.

**Command mode** Route map configuration mode.

**Usage guidelines**

Multiple access list numbers or names may follow match ip next-hop.

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

In the example below, the OSPF routing protocol redistributes the RIP routes. As long as the next hop address of the RIP route matches the access list 10 or 20, the OSPF allows for redistribution.

## Examples

```
router ospf
 redistribute rip subnets route-map redrip
 network 192.168.12.0 0.0.0.255 area 0

access-list 10 permit 192.168.100.1
access-list 20 permit 172.16.10.1

route-map redrip permit 10
 match ip next-hop 10 20
```

|------------------------------|----------------------------------------------------|
| <b>access-list</b>           | Set the access list.                               |
| <b>match ip address</b>      | Match the IP address in the access list.           |
| <b>match interface</b>       | Match the next-hop interface of the route.         |
| <b>match ip route-source</b> | Match the route source address in the access list. |
| <b>match metric</b>          | Match the metric.                                  |
| <b>match route-type</b>      | Match the route type.                              |
| <b>match tag</b>             | Match the tag.                                     |
| <b>set metric</b>            | Set the metric.                                    |
| <b>set metric-type</b>       | Set the metric type.                               |
| <b>set tag</b>               | Set the tag.                                       |

## 8.20 match ip route-source

Use **match ip route-source** command to redistribute the routes whose source IP address matches the access list. Use the **no** form of this command to remove the setting.

```
match ip route-source {access-list-number [access-list-number... | access-list-name...] | access-list-name [access-list-number... | access-list-name] | prefix-list prefix-list-name [prefix-list-name...]}
```

```
no match ip route-source [access-list-number [access-list-number... | access-list-name...] | access-list-name [access-list-number... | access-list-name] | prefix-list prefix-list-name [prefix-list-name...]]
```

| Parameter  | Description                     |
|------------|---------------------------------|
| $\alpha$   | Learning rate                   |
| $\beta_1$  | Momentum coefficient            |
| $\beta_2$  | Squared gradient moving average |
| $\epsilon$ | Tolerance for training error    |
| $\gamma$   | Discount factor                 |
| $\eta$     | Step size                       |
| $\lambda$  | Lambda regularization parameter |
| $\mu$      | Mean of Gaussian prior          |
| $\sigma^2$ | Variance of Gaussian prior      |
| $\tau$     | Temperature parameter           |
| $\omega$   | Weight decay parameter          |
| $\phi$     | Feature vector                  |
| $\psi$     | Latent variable                 |
| $\theta$   | Model parameters                |
| $\xi$      | Noise parameter                 |
| $\zeta$    | Regularization parameter        |
| $\kappa$   | Kernel function                 |
| $\nu$      | Normal distribution             |
| $\rho$     | Density function                |
| $\sigma$   | Standard deviation              |
| $\tau$     | Temperature                     |
| $\omega$   | Angular frequency               |
| $\phi$     | Potential function              |
| $\psi$     | Wavefunction                    |
| $\theta$   | Theta angle                     |
| $\xi$      | Alexis de Males                 |
| $\zeta$    | Zeta function                   |
| $\kappa$   | Kelvin                          |
| $\nu$      | Nuclide symbol                  |
| $\rho$     | Rho function                    |
| $\sigma$   | Sigma function                  |
| $\tau$     | Tau function                    |
| $\omega$   | Omega function                  |
| $\phi$     | Phi function                    |
| $\psi$     | Psi function                    |
| $\theta$   | Theta function                  |
| $\xi$      | Xi function                     |
| $\zeta$    | Zeta function                   |
| $\kappa$   | Kappa function                  |
| $\nu$      | Nu function                     |
| $\rho$     | Rho function                    |
| $\sigma$   | Sigma function                  |
| $\tau$     | Tau function                    |
| $\omega$   | Omega function                  |
| $\phi$     | Phi function                    |
| $\psi$     | Psi function                    |
| $\theta$   | Theta function                  |
| $\xi$      | Xi function                     |
| $\zeta$    | Zeta function                   |
| $\kappa$   | Kappa function                  |
| $\nu$      | Nu function                     |
| $\rho$     | Rho function                    |
| $\sigma$   | Sigma function                  |
| $\tau$     | Tau function                    |
| $\omega$   | Omega function                  |
| $\phi$     | Phi function                    |
| $\psi$     | Psi function                    |
| $\theta$   | Theta function                  |
| $\xi$      | Xi function                     |

| <i>access-list-name</i>                    | Name of the access list           |
| <b>prefix-list</b> <i>prefix-list-name</i> | Specify the prefix list to match. |

**Default****configuration** None.**Command mode** Route map configuration mode.**Usage guidelines**

Multiple access list numbers may follow `match ip route-source`.

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more `match` or `set` commands can be executed to configure a route map. If the `match` command is not used, all the routes will be matched. If the `set` command is not used, no operation will be performed.

In the example below, the OSPF routing protocol redistributes the RIP routes. As long as the source IP address of the RIP route matches the access list 5, the OSPF allows for redistribution.

**Examples**

```
router ospf
 redistribute rip subnets route-map redrip
 network 192.168.12.0 0.0.0.255 area 0

access-list 5 permit 192.168.100.1

route-map redrip permit 10
 match ip route-source
```

| <b>set metric</b>        | Set the metric.                                   |
| <b>set metric-type</b>   | Set the metric type.                              |
| <b>set tag</b>           | Set the tag.                                      |

## 8.21 match ipv6 address

Use this command to redistribute the network routes permitted in the IPv6 access list or the IPv6 prefix list. Use the **no** form of this command to delete the setting.

**match ipv6 address** { *access-list-name* | **prefix-list** *prefix-list-name* }

**no match ipv6 address**

| Parameter<br>description | Parameter                                  | Description                            |
|--------------------------|--------------------------------------------|----------------------------------------|
|                          | <i>access-list-name</i>                    | Name of the access list.               |
|                          | <b>prefix-list</b> <i>prefix-list-name</i> | Specify the IPv6 prefix list to match. |

**Default  
configuration**      None

**Command mode**      Route map configuration mode

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

Usage guideline

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The route map can be configured very flexibly to be used for route redistribution and policy-based routing. No matter how the route map is used, the configuration principle is the same, except that different command sets are used. Even if it is used on the route redistribution, different routing protocols can use different commands with the route map. The following example enables the OSPF routing protocol to redistribute RIP routes that match access list v6acl, with the default metric being 30.

### Examples

```
ipv6 router ospf
redistribute rip subnets route-map redrip
ipv6 access-list v6acl
10 permit ipv6 2620::64 any

route-map redrip permit 10
match ipv6 address v6acl
set metric 30
```

| <b>set tag</b>               | Match the IP address.          |

## 8.27 match tag

Use this command to redistribute the network routes with the specified tag. Use the **no** form of this command to delete the setting.

**match tag** *tag* [...*tag*]

**no match tag** [*tag* [...*tag*]]

| Parameter          | Parameter  | Description |
|--------------------|------------|-------------|
| <b>description</b> | <i>tag</i> | Route tag   |

#### Default

**configuration** None

#### Command

**mode** Route map configuration mode

Multiple tags may follow the match tag command.

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

#### Usage guideline

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

In the example below, the RIP routing protocol redistributes only the routes with tag 50 and 80 in the OSPF routing domain.

```
router rip
redistribute ospf 100 route-map redrip
network 192.168.12.0
```

#### Examples

```
route-map redrip permit 10
match tag 50 80
```

## 8.28 memory-lack exit-policy

Use this command to configure a policy to preferentially exit a routing protocol when the memory reaches the lower limit. Use the **no** form of this command to restore the default policy, namely, exit the routing protocol which occupies the largest memory.

**memory-lack exit-policy { bgp | ospf | pim-sm | rip }**  
**no memory-lack exit-policy**

**Parameter  
description**

| Parameter     | Description                                                 |
|---------------|-------------------------------------------------------------|
| <b>bgp</b>    | Preferentially exit BGP when the memory is insufficient.    |
| <b>ospf</b>   | Preferentially exit OSPF when the memory is insufficient.   |
| <b>pim-sm</b> | Preferentially exit PIM-SM when the memory is insufficient. |
| <b>rip</b>    | Preferentially exit RIP when the memory is insufficient.    |

**Default**

By default, the routing protocol which occupies the largest memory exits preferentially.

**Command  
mode**

Global configuration mode

**Usage  
guideline**

When the memory reaches the lower limit, you can disable a routing protocol to release the memory to ensure the normal running of other protocols.

When the system runs out of memory, disable a routing protocol which has the minimal impact on the system to ensure the operation of main services.

Configuring the policy to preferentially exit the routing protocols which are disabled cannot help the system release memory.

This command ensures the operation of main services to some extent when the memory is insufficient.

If the memory is further consumed, all routing protocols will exit and stop running.

**Examples**

The following example configures a policy to preferentially exit the BGP protocol when the memory reaches the lower limit.

```
Ruijie(config)# memory-lack exit-policy bgp
```

## 8.29 route-map

Use **route-map** to enter the route map configuration mode and define a route map. Use the **no** form of this command to remove the setting.

**route-map** *route-map-name* [**permit** | **deny**] [*sequence-number*]

**no route-map** *route-map-name* [{**permit** | **deny**} *sequence-number*]

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>route-map-name</i>  | Name of the route map. The redistribute command references the route map according to its name. Multiple routing policies can be defined in a route map, and each policy corresponds to one sequence number.                                                                                                                                                                                                                                 |
| <b>permit</b>          | (Optional) If the permit keyword is defined and the rule defined by match is met, The set command controls the redistributed routes. For policy-based routing, the set command controls the packet forwarding, and exits the route map operation.<br><br>If the permit keyword is defined but the rule defined by match is not met, the system performs the routing policy of the second route map till the set command is executed finally. |
| <b>deny</b>            | (Optional) If the deny keyword is defined and the rule defined by match is met, no operation will be performed. Neither route redistribution nor policy-based routing is supported in the route map. The system exits the route map operation.<br><br>If the deny keyword is defined but the rule defined by match is not met, the system performs the routing policy of the second route map till the set command is executed finally.      |
| <i>sequence-number</i> | Sequence number of the route map. The policy with a lower sequence number is preferred, so it's noted when setting the sequence number.                                                                                                                                                                                                                                                                                                      |

|                              |                            |
|------------------------------|----------------------------|
| <b>Default configuration</b> | None.                      |
| <b>Command mode</b>          | Global configuration mode. |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage guidelines</b> | <p>At present, the RGOS software primarily uses the route map for route redistribution and policy-based routing.</p> <p>1. Route redistribution control</p> <p>You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.</p> <p>For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.</p> <p>One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.</p> <p>When configuring route maps, pay attention to the following when using the sequence number of a route map:</p> |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

When you create the first route map policy, if *sequence-number* is not specified, it is 10 by default;

If only one route map policy exists and *sequence-number* is not specified, no new route map policy will be created, and the existing route map policy will be accessed for configuration;

If more than one route map policy is available, the sequence number of each policy shall be specified; otherwise an error message will be displayed.

## 2. policy-based routing

Policy-based routing refers to a routing mechanism based on user defined policies.

Compared with traditional destination IP address-based routing, policy-based routing offers a flexibility for routing based on source IP address, length and port of IP packets.

Policy-based routing can apply to the IP packets received on an interface or the IP packets sent from the local device.

Policy-based routing utilizes route map to define routing and forwarding policy. The match command defines packet filtering rule and the set command defines the action for the packets matching the filtering rules. The match command used includes match ip address and match length; the set command includes set ip tos, set ip precedence, set ip dscp, set ip [default] nexthop, set ip next-hop verify-availability, set [default] interface.

The following example enables the OSPF routing protocol to redistribute the RIP routes with the hop count of 4. In the OSPF route domain, the route type is the external route type-1, the default metric is 40 and the tag is 40.

### Examples

```
!  
router ospf  
  redistribute rip subnets route-map redrip  
  network 192.168.12.0 0.0.0.255 area 0  
!  
!  
route-map redrip permit 10  
  match metric 4  
  set metric 40  
  set metric-type type-1  
  set tag 40
```

### Related commands

| Command      | Description              |
|--------------|--------------------------|
| redistribute | Redistribute the routes. |

## 8.30 send-lifetime

Use this command in the encryption key configuration mode to specify the lifetime of an encryption key in its send direction. Use the no form of this command to restore the default value.

**send-lifetime** *start-time* {**infinite** | *end-time* | **duration** *seconds*}

**no send-lifetime**

| Parameter   | Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| description | <i>start-time</i> | Start time of the lifetime. The syntax is as follows:<br><i>hh:mm:ss month date year</i><br><i>hh:mm:ss date month year</i><br><ul style="list-style-type: none"><li>● hh—hour</li><li>● mm—minute</li><li>● ss—second</li><li>● month—month</li><li>● date—day</li><li>● year—year</li></ul> The default start time is Jun 1, 1993, which is also the earliest start time available. |
|             | <b>infinite</b>   | Indicates that the encryption key is valid for ever.                                                                                                                                                                                                                                                                                                                                  |
|             | <i>end-time</i>   | <i>End time of the encryption key. It must be later than the start time.</i>                                                                                                                                                                                                                                                                                                          |
|             | <b>duration</b>   | Duration of the encryption key after the start time. The value ranges from 1 to 2147483646.                                                                                                                                                                                                                                                                                           |
|             | <i>seconds</i>    |                                                                                                                                                                                                                                                                                                                                                                                       |

**Default**      infinite

**Command mode**      Encryption key configuration mode

**Usage guideline**      Use this command to specify the lifetime of an encryption key in its send direction.

**Examples**      The following example configures the lifetime from 0:00 on September 9, 2000 to 0:00 on October 12, 2011

```
Ruijie(config)# key chain ripkeys
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)# send-lifetime 00:00:00 Sep 9 2000 00:00:00 Dec 12 2011
```

**Platform description**      -

## 8.31 set aggregator as

Use this command to specify the AS\_PATH attribute for the aggregator of the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set aggregator as** *as-number ip\_addr*

**no set aggregator as** [*as-number ip\_addr*]

| Parameter   | Parameter         | Description                  |
|-------------|-------------------|------------------------------|
| description | <i>as-number</i>  | AS number of the aggregator  |
|             | <i>ip_address</i> | IP address of the aggregator |

**Default configuration** None

**Command mode** Route map configuration mode

**Usage guideline** Use this command to set the AS\_PATH attribute for the matched routes in the BGP routing domain. Only one group of parameters (as-number, ip-addr) is allowed to set at a time.

### Examples

```
Ruijie(config)# route-map set-as-path
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set aggregator as 3 2.2.2.2
```

| Related commands | Command         | Description                  |
|------------------|-----------------|------------------------------|
|                  | match as-path   | Match the AS_PATH.           |
|                  | match community | Match the community.         |
|                  | match metric    | Match the route metric.      |
|                  | match origin    | Match the route source.      |
|                  | set community   | Set the COMMUNITY attribute. |
|                  | set metric      | Set the metric.              |
|                  | set metric-type | Set the type.                |

## 8.32 set as-path replace

Use this command to replace the AS\_PATH attribute for the routes that match the rule in the route map

configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set as-path replace** *as-number*

**no set as-path replace**

| Parameter description | Parameter        | Description                                                                                                                                    |
|-----------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>as-number</i> | Indicates the AS number which will replace the AS_PATH attribute. The AS number ranges from 1 to 4294967295, and 1 to 65535.65535 in dot mode. |

**Default configuration** N/A

**Command mode** Route map configuration mode

**Usage guideline** Use this command to replace the AS\_PATH attribute for the matched routes. Up to 10 ASs can be added into the as-path for one time.

The following example replaces the AS\_PATH attribute “100 101 102” for the route matched with AS path 1.

**Examples**

```
Ruijie(config)# route-map set-as-path
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set as-path replace 100 101 102
```

## 8.33 set as-path prepend

Use this command to specify the AS\_PATH attribute for the routes that match the rule in the route map configuration mode.

Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set as-path prepend** *as-number*

**no set as-path prepend**

| Parameter description | Parameter        | Description                                                                                                                          |
|-----------------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>as-number</i> | AS number of the AS_PATH attribute to be configured.<br>The AS number ranges from 1 to 4294967295, and 1 to 65535.65535 in dot mode. |

**Default configuration** None

**Command**

**mode** Route map configuration mode

**Usage guideline** Use this command to configure the AS\_PATH attribute for the matched routes. Up to 15 ass can be added into the as-path for one time.

**Examples**

```
Ruijie(config)# route-map set-as-path
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set as-path prepend 100 101 102
```

**Related commands**

| Command                | Description                  |
|------------------------|------------------------------|
| <b>match as-path</b>   | Match the AS_PATH.           |
| <b>match community</b> | Match the community.         |
| <b>match metric</b>    | Match the route metric.      |
| <b>match origin</b>    | Match the route source.      |
| <b>set community</b>   | Set the COMMUNITY attribute. |
| <b>set metric</b>      | Set the metric.              |
| <b>set metric-type</b> | Set the type.                |

## 8.34 set atomic-aggregate

Use this command to set the ATOMIC-AGGREGATE attribute for routes.

**set atomic-aggregate**

Use the **no** form of this command to delete existing configuration.

**no set atomic-aggregate**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Routing map configuration mode

**Default Level** 14

**Usage Guide** This command is used only in the BGP protocol and is used to set the ATOMIC-AGGREGATE attribute for routes.

**Configuration**  
**Examples**      N/A

## 8.35 set comm-list delete

Use this command to delete the COMMUNITY\_LIST attribute for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set comm-list** *community-list-number* | *community-list-name* **delete**

**no set comm-list** *community-list-number* | *community-list-name* **delete**

**Parameter  
description**

| Parameter                    | Description                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <i>community-list-number</i> | Number of the community list.<br>Standard community list number: 1-99.<br>Extended community list number : 100-199. |
| <i>community-list-name</i>   | Name of the community list, which should be no more than 80 characters.                                             |

**Default  
configuration**      None

**Command mode**      Route map configuration mode

**Usage guideline**      Use this command to set the community attribute value for the matched routes that will be deleted.

**Examples**

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 172.16.233.33 remote-as 120
Ruijie(config-router)# neighbor 172.16.233.33 route-map ROUTEMAPIN in
Ruijie(config-router)# neighbor 172.16.233.33 route-map ROUTEMAPOUT out
Ruijie(config-router)# exit
Ruijie(config)# ip community-list 500 permit 100:10
Ruijie(config)# ip community-list 500 permit 100:20
Ruijie(config)# ip community-list 120 deny 100:50
Ruijie(config)# ip community-list 120 permit 100:.*
Ruijie(config)# route-map ROUTEMAPIN permit 10
Ruijie(config-route-map)# set comm-list 500 delete
Ruijie(config-route-map)# exit
Ruijie(config)# route-map ROUTEMAPOUT permit 10
Ruijie(config-route-map)# set comm-list 120 delete
```

### Related commands

| Command                     | Description                                              |
|-----------------------------|----------------------------------------------------------|
| <b>match as-path</b>        | Match the AS_PATH attribute value.                       |
| <b>match metric</b>         | Match the metric.                                        |
| <b>match origin</b>         | Match the source.                                        |
| <b>set as-path prepend</b>  | Set the AS_PATH attribute.                               |
| <b>set local-preference</b> | Set the local priority of the route to be redistributed. |
| <b>set metric-type</b>      | Set the metric type.                                     |

## 8.36 set community

Use this command to specify the community for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set community** {*community-number*[*community-number*...]} [**additive** | **none**]

**no set community**

### Parameter description

| Parameter               | Description                                                                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>community-number</i> | Community number in the form of AA:NN or a large numeral. In addition, it can be well-known community attributes like internet, local-AS, no-export and no-advertise. |
| additive                | Increase on the original COMMUNITY attribute.                                                                                                                         |
| none                    | Set the community attribute as blank.                                                                                                                                 |

### Default

**configuration** None

**Command mode** Route map configuration mode

**Usage guideline** Use this command to set the community attribute for the matched route.

### Examples

```
Ruijie(config)# route-map SET_COMMUNITY 10 permit
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set community 109:10
Ruijie(config-route-map)# exit
Ruijie(config)# route-map SET_COMMUNITY 20 permit
Ruijie(config-route-map)# match as-path 2
Ruijie(config-route-map)# set community no-export
```

**Related  
commands**

| Command                    | Description                |
|----------------------------|----------------------------|
| <b>match as-path</b>       | Match the AS_PATH.         |
| <b>match community</b>     | Match the community.       |
| <b>match metric</b>        | Match the metric.          |
| <b>match origin</b>        | Match the source.          |
| <b>set as-path prepend</b> | Set the AS_PATH attribute. |
| <b>set origin</b>          | Set the source.            |
| <b>set metric-type</b>     | Set the metric type.       |

## 8.37 set dampening

Use this command to specify the dampening parameters for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set dampening** *half-life reuse suppress max-suppress-time* [withdrawal-ignore]

**no set dampening**

**Parameter  
description**

| Parameter                | Description                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <i>half-life</i>         | Half dampening life for the reachable or unreachable route in the range of 1 to 45 minutes, 15 minutes by default                 |
| <i>reuse</i>             | When the route penalty is lower than this value, the route suppression is released. It is in the range 1 to 20000, 750 by default |
| <i>suppress</i>          | When the route penalty is higher than this value, the route is suppressed. It is in the range 1 to 20000, 2000 by default         |
| <i>max-suppress-time</i> | Maximum duration a route can be suppressed in the range 1 to 20000 minutes, 4* half-life by default.                              |
| <i>withdrawal-ignore</i> | Not to increase the penalty value for route cancellation.                                                                         |

**Default****configuration**

None

**Command mode**

Route map configuration mode

**Usage guideline**

Use this command to set the dampening parameter for the matched routes.

**Examples**

```

Ruijie(config)# route-map tag
Ruijie(config-route-map)# match as path 10
Ruijie(config-route-map)# set dampening 30 1500 10000 120
withdrawal-ignore
Ruijie(config-route-map)# exit
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 172.16.233.52 route-map tag in

```

**Related commands**

| Command                     | Description                                              |
|-----------------------------|----------------------------------------------------------|
| <b>match as-path</b>        | Match the AS_PATH value.                                 |
| <b>match community</b>      | Match the community.                                     |
| <b>match metric</b>         | Match the metric.                                        |
| <b>match origin</b>         | Match the source.                                        |
| <b>set as-path prepend</b>  | Set the AS_PATH attribute.                               |
| <b>set metric</b>           | Set the metric.                                          |
| <b>set local-preference</b> | Set the local priority of the route to be redistributed. |

## 8.38 set distance

Use this command to set the management distance for routes matching the match rule. Use the **no** form of this command to delete the specified management distance.

**set distance** { *number* }

**no set distance**

**Parameter Description**

| Parameter     | Description                                                    |
|---------------|----------------------------------------------------------------|
| <i>number</i> | Route management distance, ranging from <b>1</b> to <b>255</b> |

**Defaults** N/A

**Command Mode** Routing map configuration mode

**Default Level** 14

**Usage Guide** The route management distance affects route selection. Therefore, set the route management distance according to the actual network topology.

**Configuration** The following example configures the OSPF routing protocol and sets the OSPF route management

**Example** distance to 112.

```
Ruijie(config)# route-map test
Ruijie(config-route-map)# set distance 112
Ruijie(config)#exit
Ruijie(config)# router ospf 1
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# distance 111 route-map test
Ruijie(config-router)# exit
```

**Verification** Run the **show running-config** command to display the configurations.

**Prompt Messages** N/A

**Common Errors** N/A

**Platform** N/A

**Description**

## 8.39 set extcomm-list delete

Use this command to delete all extcommunity values in the extcommunity list that meet the match rules. Use the **no** form of this command to delete the configuration.

**set extcomm-list** { *extcommunity-list-number* | *extcommunity-list-name* } **delete**

**no set extcomm-list** { *extcommunity-list-number* | *extcommunity-list-name* } **delete**

**Parameter description**

| Parameter                       | Description                                                                                                      |
|---------------------------------|------------------------------------------------------------------------------------------------------------------|
| <i>extcommunity-list-number</i> | <i>extcommunity-list-number</i><br>Standard list: ranges from 1 to 99.<br>Expanded list: ranges from 100 to 199. |
| <i>extcommunity-list-name</i>   | <i>extcommunity-list-name</i><br>It consists of a maximum of 80 characters.                                      |

**Default** -

**Command mode** Route map configuration mode.

**Usage** This command is used to delete the **extcommunity-list**.

**guideline** This command applies only to policy route configuration.

**Examples** Ruijie(config)# router bgp 65530

```

Ruijie(config-router)# neighbor 172.16.233.33 remote-as 65531
Ruijie(config-router)# address-family vpnv4 unicast
Ruijie(config-router-af)# neighbor 172.16.233.33 activate
Ruijie(config-router-af)# neighbor 172.16.233.33 route-map ROUTEMAPIN in
Ruijie(config-router-af)# neighbor 172.16.233.33 route-map ROUTEMAPOUT out
Ruijie(config-router)# exit
Ruijie(config)# ip extcommunity-list 10 permit rt 100:10
Ruijie(config)# ip extcommunity-list 10 permit rt 100:20
Ruijie(config)# ip extcommunity-list 120 deny 100:50
Ruijie(config)# ip extcommunity-list 120 permit 100:.*
Ruijie(config)# route-map ROUTEMAPIN permit 10
Ruijie(config-route-map)# set extcomm-list 10 delete
Ruijie(config-route-map)# exit
Ruijie(config)# route-map ROUTEMAPOUT permit 10
Ruijie(config-route-map)# set extcomm-list 120 delete

```

**Related  
command**

| Command                        | Description                             |
|--------------------------------|-----------------------------------------|
| <b>ip extcommunity-list</b>    | Configure an <b>extcommunity-list</b> . |
| <b>match as-path</b>           | Match the AS_PATH value                 |
| <b>match metric</b>            | Match the metric.                       |
| <b>match origin</b>            | Match the source.                       |
| <b>set as-path prepend</b>     | Set the AS_PATH attribute.              |
| <b>set extcomm-list delete</b> | Set delete <b>extcommunity-list</b> .   |
| <b>set local-preference</b>    | Set local preference for a reroute.     |

**Platform  
description**

-

## 8.40 set extcommunity

Use this command to specify the extended COMMUNITY attribute for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set extcommunity** {rt *extend-community-value* | **soo** *extend-community-value*}

**no set extcommunity** {rt | **soo** }

**Parameter  
description**

| Parameter                     | Description                                              |
|-------------------------------|----------------------------------------------------------|
| rt                            | Specify the extended community value in the form of RT.  |
| soo                           | Specify the extended community value in the form of SOO. |
| <i>extend-community-value</i> | Extended community value.                                |

**Default****configuration** None**Command mode** Route map configuration mode**Usage guideline** Use this command to set the extended community attribute for the matched route.**Examples**

```

Ruijie(config)# access-list 2 permit 192.168.78.0 255.255.255.0
Ruijie(config)# route-map MAP_NAME permit 10
Ruijie(config-route-map)# match ip-address 2
Ruijie(config-route-map)# set extcommunity rt 100:2

```

**Related commands**

| Command                    | Description                |
|----------------------------|----------------------------|
| <b>match as-path</b>       | Match the AS_PATH value    |
| <b>match community</b>     | Match the community.       |
| <b>match metric</b>        | Match the metric.          |
| <b>match origin</b>        | Match the source.          |
| <b>set as-path prepend</b> | Set the AS_PATH attribute. |
| <b>set metric</b>          | Set the metric.            |
| <b>set metric-type</b>     | Set the metric type.       |

## 8.41 set fast-reroute

Use this command to specify a backup outgoing fast reroute and a backup next-hop for routes that meet the match conditions. Use the no form of this command to delete the configuration.

**set fast-reroute backup-interface** *interface-type interface-number* [ **backup-nexthop** *ip-address* ]  
**no set fast-reroute**

**Parameter description**

| Parameter                              | Description                |
|----------------------------------------|----------------------------|
| <i>interface-type interface-number</i> | Backup outgoing interface. |
| <i>ip-address</i>                      | Backup next-hop.           |

**Default** -**Command mode**

Route map configuration mode.

**Usage**

Use this command to configure IP FRR backup outgoing interface and backup next-hop. The current

**guideline** software version supports only one backup route. This command supports only one set of the two parameters.

This command is used for fast reroute configuration.

 IP FRR backup routes must not be direct-connection or local host routes.

**Examples**

```
Ruijie(config)# access-list 2 permit 192.168.78.0 255.255.255.0
Ruijie(config)# route-map frr permit 10
Ruijie(config-route-map)# match ip-address 2
Ruijie(config-route-map)# set fast-reroute backup-interface GigabitEthernet
0/1 backup-nexthop 192.168.1.2
```

| Related<br>command | Command          | Description            |
|--------------------|------------------|------------------------|
|                    | match ip-address | Match IP address list. |

**Platform** N/A

**description**

## 8.42 set ip default next-hop

Use this command to specify the default next-hop IP address for the packets that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set ip default next-hop** *ip-address* [*weight*] [...*ip-address*[*weight*]]

**no set ip default next-hop** [*ip-address* [*weight*] [...*ip-address*[*weight*]]]

| Parameter<br>description | Parameter         | Description                 |
|--------------------------|-------------------|-----------------------------|
|                          | <i>ip-address</i> | IP address of the next hop. |
|                          | <i>weight</i>     | Weight of the next hop.     |

**Default  
configuration** None

**Command mode** Route map configuration mode

**Usage guideline**

This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In the former mode, the system implements WCMP load balancing according to the weight inputted.

Up to 32 IP addresses may follow the set ip default next-hop command.

If a weight follows ip address, up to 4 next hop IP addresses can be configured.

**Note:** If a weight follows any next-hop, the operation mode of this command will be automatically switched to the WCMP load balancing mode. In this mode, the weight of those next hop IP addresses whose weight is not configured is 1 by default.

Differences between set ip next-hop and set ip default next-hop: After the set ip next-hop command is configured, the policy-based routing takes precedence over the routing table; while after the set ip default next-hop command is configured, the routing table takes precedence over the policy-based routing.

Use this command to customize a default route for a specified user. If the software fails to find the forwarding route, the packet will be forwarded to the nexthop set with this command. To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded through the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy. A route-map policy may contain multiple set operations.

The following example forwards the packets from two different nodes through different routes.

For the messages received on the synchronous interface 1 from 1.1.1.1, if the software cannot find the forwarding route, they are forwarded to device 6.6.6.6. For the messages received from 2.2.2.2, if the software cannot find the forwarding route, they are forwarded to device 7.7.7.7. The other messages will be discarded if the software cannot find the forwarding route.

### Examples

```
Ruijie(config)#access-list 1 permit 1.1.1.1 0.0.0.0
Ruijie(config)#access-list 2 permit 2.2.2.2 0.0.0.0
Ruijie(config)#interface async 1
Ruijie(config-if)#ip policy route-map equal-access
Ruijie(config)#route-map equal-access permit 10
Ruijie(config- route-map)#match ip address 1
Ruijie(config-route-map)#set ip default next-hop 6.6.6.6
Ruijie(config)#route-map equal-access permit 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set ip default next-hop 7.7.7.7
Ruijie(config)#route-map equal-access permit 30
Ruijie(config- route-map)#set default interface null 0
```

| <b>route-map</b>             | Define a route map.                 |
| <b>match ip address</b>      | Match the IP address.               |
| <b>set default interface</b> | Set the default outgoing interface. |

|                          |                                  |
|--------------------------|----------------------------------|
| <b>set interface</b>     | Set the outgoing interface.      |
| <b>set ip next-hop</b>   | Set the next hop of the packets. |
| <b>set ip precedence</b> | Set the priority of the packets. |

**Platform**

**description** N/A

## 8.43 set ip dscp

Use this command to specify the DSCP value for the packets that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set ip dscp** *dscp-value*

**no set ip dscp**

**Parameter****description**

| Parameter         | Description |
|-------------------|-------------|
| <i>dscp-value</i> | DSCP value  |

**Default**

**configuration** N/A

**Command mode** Route map configuration mode

**Usage guideline** N/A

**Examples** N/A

**Related  
commands**

| Command                      | Description                         |
|------------------------------|-------------------------------------|
| <b>route-map</b>             | Define a route map.                 |
| <b>match ip address</b>      | Match the IP address.               |
| <b>set default interface</b> | Set the default outgoing interface. |
| <b>set interface</b>         | Set the outgoing interface.         |
| <b>set ip next-hop</b>       | Set the next hop of the packets.    |
| <b>set ip precedence</b>     | Set the priority of the packets.    |

## 8.44 set ip next-hop

Use this command to specify the next-hop IP address for the packets that meet the matching rule. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set ip next-hop** *ip-address* [*weight*] [...*ip-address* [*weight*]]

**no set ip next-hop** [*ip-address* [*weight*] [...*ip-address* [*weight*]]]

| Parameter description | Parameter         | Description                 |
|-----------------------|-------------------|-----------------------------|
|                       | <i>ip-address</i> | IP address of the next hop. |
|                       | <i>weight</i>     | Weight of the next hop.     |

**Default configuration** None

**Command mode** Route map configuration mode

This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In the former mode, the system implements WCMP load balancing according to the weight entered by the user.

Multiple IP addresses may follow set ip next-hop and the number of addresses should be less than 32.

If weight follows any next-hop, the operation mode of this command will be automatically switched to the WCMP load balancing mode. In the WCMP load balancing mode, for the nexthop address without configuring the corresponding weight, the weight is 1 by default.

#### Usage guideline

If weight follows ip address, up to 4 next hop addresses can be configured.

This command can be used to set different routes for the traffic that meets different match rule. If multiple IP addresses are configured, they can be used in turn.

Policy-based routing is a packet forwarding mechanism more flexible than the routing based on the target network. After the policy-based routing is used, the device will decide how to process the packets that need be routed according to the route map, which decides the next-hop device of the packets.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

A route-map policy may contain multiple set operations.

#### Examples

The following example enables policy-based routing on serial 1/0. When the interface receives the packets from 10.0.0.0/8, they will be sent to 192.168.100.1; when the interface receives the packets from 172.16.0.0/16, they will be sent to 172.16.100.1; all other packets

will be discarded.

```
Ruijie(config)#interface serial 1/0
Ruijie(config-if)#ip policy route-map load-balance
Ruijie(config)#access-list 10 permit 10.0.0.0 0.255.255.255
Ruijie(config)#access-list 20 permit 172.16.0.0 0.0.255.255
Ruijie(config)#route-map load-balance permit 10
Ruijie(config-route-map)#match ip address 10
Ruijie(config-route-map)#set ip next-hop 192.168.100.1
Ruijie(config)#route-map load-balance permit 20
Ruijie(config-route-map)#match ip address 20
Ruijie(config-route-map)#set ip next-hop 172.16.100.1
Ruijie(config)#route-map load-balance permit 30
Ruijie(config-route-map)#set interface Null 0
```

#### Related commands

| Command                        | Description                         |
|--------------------------------|-------------------------------------|
| <b>route-map</b>               | Define the route map.               |
| <b>match ip address</b>        | Match the IP address.               |
| <b>set default interface</b>   | Set the default outgoing interface. |
| <b>set interface</b>           | Set the outgoing interface.         |
| <b>set ip default next-hop</b> | Set the default next hop.           |
| <b>set ip precedence</b>       | Set the priority of the packets.    |

## 8.45 set ip next-hop recursive

Use this command to specify the recursive next-hop IP address for data packets that match a rule.

**set ip [ vrf *vrf-name* | global ] next-hop recursive *ip-address***

Use the **no** form of this command to delete the configured next-hop IP address.

**no set ip [ vrf *vrf-name* | global ] next-hop recursive**

#### Parameter Description

| Parameter                  | Description                                        |
|----------------------------|----------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i> | The next hop address belongs to the specified VRF. |
| <b>global</b>              | The next hop address belongs to the global.        |
| <i>ip-address</i>          | Recursive next-hop IP address                      |

**Defaults** N/A

**Command** Routing map configuration mode

**Mode****Default Level** 14

**Usage Guide** This command is used only to configure PBR. Only one **set ip next-hop recursive** *ip-address* command can be configured in one routing submap policy.

According to the policy, only static or dynamic routes that have an egress and next-hop IP address can be recursed. A route can be recursed to 32 next-hop IP addresses. Only one static route can be recursed to the next hop IP address.

**Examples** The following example enables PBR on Interface serial 1/0. The interface sends the data packets from the source IP address of 10.0.0.0/8 to the recursive next-hop IP address 192.168.100.1, sends the traffic from the source network 172.16.0.0/16 to the recursive next-hop IP address 172.16.100.1, and forwards other data traffic via common routes.

```
Ruijie(config)#interface serial 1/0
Ruijie(config-if)#ip policy route-map load-balance
Ruijie(config)#access-list 10 permit 10.0.0.0 0.255.255.255
Ruijie(config)#access-list 20 permit 172.16.0.0 0.0.255.255
Ruijie(config)#route-map load-balance permit 10
Ruijie(config-route-map)#match ip address 10
Ruijie(config-route-map)#set ip next-hop recursive 192.168.100.1
Ruijie(config)#route-map load-balance permit 20
Ruijie(config-route-map)#match ip address 20
Ruijie(config-route-map)#set ip next-hop recursive 172.16.100.1
```

## 8.46 set ip next-hop verify-availability

Use this command to verify the availability of the next hop IP address for the packets that meet the matching rule. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set ip** [ **vrf** *vrf-name* | **global** ] **next-hop verify-availability** *ip-address* [**track** *track-obj-number* | **bfd** *interface-type interface-number gateway* ]

**no set ip** [ **vrf** *vrf-name* | **global** ] **next-hop verify-availability** *ip-address* [**track** *track-obj-number* | **bfd** *interface-type interface-number gateway* ]

**Parameter description**

| Parameter                  | Description                                        |
|----------------------------|----------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i> | The next hop address belongs to the specified VRF. |
| <b>global</b>              | The next hop address belongs to the global.        |
| <i>ip-address</i>          | Indicates the next-hop IP address.                 |

|                         |                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>track</b>            | Judges whether the next hop is effective by using <i>Track</i> .                                                                                                                                |
| <i>track-object-num</i> | Indicates the track object number.                                                                                                                                                              |
| <b>bfd</b>              | Indicates that BFD is used for neighbor detection.                                                                                                                                              |
| <i>interface-type</i>   | Configures the interface type.                                                                                                                                                                  |
| <i>interface-number</i> | Configures the interface number.                                                                                                                                                                |
| <i>gateway</i>          | Configures the gateway IP address, which is the neighbor IP address of BFD. If the next hop is configured as the neighbor, BFD will be used to detect the accessibility of the forwarding path. |

**Default****configuration**    None**Command****mode**                Route map configuration mode**Usage****guideline**          None

The following example verifies the availability of the next hop IP address being 192.168.1.2 and the number of the object to be tracked to 1.

**Examples**

```
Ruijie(config)#route-map rmap permit 10
Ruijie(config-route-map)#set ip next-hop verify-availability 192.168.1.2
track 1
```

**Related  
commands**

|                          | <i>number</i>                                                                                                                                   | Indicates the priority of the IP header with a number, ranging from 0 to 7.<br>7: critical<br>6: flash<br>5: flash-override<br>4: immediate<br>3: internet<br>2: network<br>1: priority<br>0: routine |
|                          | <b>critical</b>   <b>flash</b>   <b>flash-override</b>   <b>immediate</b>   <b>internet</b>   <b>network</b>   <b>priority</b>   <b>routine</b> | Priority of an IP header.                                                                                                                                                                             |

**Defaults** N/A

**Command mode** Route map configuration mode

**Usage guideline** With different precedence values for the IP packet head configured, the IP packets matching the PBR routing are sent according to the different precedence values.  
Multiple set ip precedence commands can be executed in the route map configuration rule, but only the last one takes effect, and the precedence will be specified for the head of the IP packet matched the PBR.

The following example sets the precedence of the packet with the source IP address 192.168.217.68 received at the interface FastEthernet 0/0 as 4:

#### Examples

```
Ruijie(config)#access-list 1 permit 192.168.217.68 0.0.0.0
Ruijie(config)#route-map name
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip precedence 4
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ip policy route-map name
```

Related  
commands

| Command                      | Description                                   |
|------------------------------|-----------------------------------------------|
| <b>match interface</b>       | Match the next-hop interface.                 |
| <b>match ip address</b>      | Match the IP address in the ACL.              |
| <b>match ip next-hop</b>     | Match the next-hop IP address in the ACL.     |
| <b>match ip route-source</b> | Match the route source IP address in the ACL. |
| <b>match metric</b>          | Match the route metric value.                 |
| <b>match route-type</b>      | Match the route type.                         |
| <b>match tag</b>             | Match the route tag value.                    |
| <b>set metric-type</b>       | Set the type of redistributed route.          |
| <b>set tag</b>               | Set the tag value of redistributed route.     |
| <b>set ip tos</b>            | Set the tos for the IP packet head.           |

## 8.48 set ip tos

Use this command to set the tos of the IP head of the packet matching the rule in the route map configuration mode. Use the **no** form of this command to remove the configured tos setting.

**set ip tos** {<0-15> | *max-reliability* | *max-throughput* | *min-delay* | *min-monetary-cost* | *normal*}

**no set ip tos**

### Default

**configuration** N/A

**Command mode** Route map configuration mode

### Usage guideline

With different TOS values for the IP packet head configured, the IP packets matching the PBR routing are transmitted with different service qualities.

The TOS value will be specified for the head of the IP packet matched the PBR.

### Examples

The following example sets the TOS value of the packet with the source IP address 192.168.217.68 received at the interface FastEthernet 0/0 as 4:

```
Ruijie(config)#access-list 1 permit 192.168.217.68 0.0.0.0
Ruijie(config)#route-map name
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip tos 4
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ip policy route-map name
```

### Related commands

| <b>match route-type</b>      | Match the route type.                         |
| <b>match tag</b>             | Match the route tag value.                    |
| <b>set metric-type</b>       | Set the type of redistributed route.          |
| <b>set tag</b>               | Set the tag value of redistributed route.     |
| <b>set ip precedence</b>     | Set the precedence for the IP packet head.    |

## 8.49 set ipv6 default next-hop

Use this command to specify the default next-hop IPv6 address for the IPv6 packets that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set ipv6 default next-hop** *global-ipv6-address* [*weight*] [...*ipv6-address*[*weight*]]

**no set ipv6 default next-hop** *global-ipv6-address* [*weight*] [...*ipv6-address*[*weight*]]

### Parameter description

| Parameter                  | Description                                                                    |
|----------------------------|--------------------------------------------------------------------------------|
| <i>global-ipv6-address</i> | IPv6 address of the next hop. The next hop router must be the neighbor router. |
| <i>weight</i>              | Weight in the load balancing mode, in the range of 1 to 8.                     |

### Default

**configuration** None

**Command mode** Route map configuration mode

### Usage guideline

With the policy-based routing applied to the interface, for the IPv6 packets matching the corresponding rules, if the usual route (that is the non default route) with the destination of this packet is not in the routing table, this packet will be forwarded to the next hop specified by the set ipv6 default next-hop command. Otherwise it is forwarded through the usual route. Noted that the match rule should be the IPv6 corresponded.

Packets select the egress from the policy-based routing and routing table in following priority.

set ipv6 next-hop;

usual route (the non default route)

set ipv6 default next-hop

default route.

 For the switches, this function does not take effect if the mask length is beyond 64.

 If this command and the set ipv6 next-hop verify-availability are both configured ,the next hop set by the set ipv6 next-hop verify-availability command will take effect preferentially

### Examples

The following examle sets the default next hop of the packet with destination address `2001:0db8:2001:1760::/64` received at the interface `fastEthernet 0/0` as `2002:0db8:2003:1::95`

```
Ruijie(config)# ipv6 access-list acl_for_pbr
Ruijie(config-ipv6-acl)#permit ipv6 any 2001:0db8:2001:1760::/64
Ruijie(config)#route-map rm_if_0_0
Ruijie(config-route-map)#match ipv6 address acl_for_pbr
Ruijie(config-route-map)# set ipv6 default next-hop
2002:0db8:2003:1::95
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ipv6 policy route-map rm_if_0_0
```

### Related commands

| <b>match ipv6 address</b>    | Set the matching rule of policy-based routing. |
| <b>ipv6 policy route-map</b> | Use the policy-based routing on the interface. |
| <b>set ipv6 next-hop</b>     | Set the next hop of the policy-based routing.  |

### Platform

description N/A

## 8.50 set ipv6 fast-reroute

Use this command to specify the FRR backup egress and next hop for routes matching the match rule. Use the **no** form of this command to delete the FRR configuration.

**set ipv6 fast-reroute backup-interface** *interface-type interface-number* [ **backup-nexthop** *ipv6-address* ]  
**no set ipv6 fast-reroute**

### Parameter Description

| Parameter             | Description   |
|-----------------------|---------------|
| <i>interface-type</i> | Backup egress |

|                         |                                                   |
|-------------------------|---------------------------------------------------|
| <i>interface-number</i> |                                                   |
| <i>ipv6-address</i>     | Backup next hop, mandatory for non-P2P interfaces |

**Defaults** N/A

**Command Mode** Routing map configuration mode

**Default Level** 14

**Usage Guide** This command is used only to configure FRR.  
Use this command to configure the backup egress and next hop of IPv6 FRR. The current software version supports only one backup route, and this command supports only one group of <interface, next hop> parameters.

 The FRR backup entry should not be a direct or local host route.

**Configuration Example** The following example configures a route map and sets the backup egress to GigabitEthernet 0/1 and backup next hop to 2001::1 for routes matching ACL 2.

```
Ruijie(config)# access-list 2 permit 2001::/64
Ruijie(config)# route-map frr permit 10
Ruijie(config-route-map)# match ip-address 2
Ruijie(config-route-map)# set ipv6 fast-reroute backup-interface GigabitEthernet
0/1 backup-nexthop 2001::1
```

**Verification** Run the **show running-config** command to display the configurations.

**Prompt** The specified interface is an L2 interface, for example, GigabitEthernet 0/0.

**Messages** % Invalid parameter: GigabitEthernet 0/0, only support layer 3 interface.

## 8.51 set ipv6 next-hop

Use this command to specify the next-hop IPv6 address for the packets that meet the matching rule. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set ipv6 next-hop** [**vrf** *vrf-name* | **global**] *global-ipv6-address* [*weight*] [...*global-ipv6-address* [*weight*]]

**no set ip next-hop** [**vrf** *vrf-name* | **global**] *global-ipv6-address* [*weight*] [...*global-ipv6-address* [*weight*]]

**Parameter description**

| Parameter                  | Description                                                                      |
|----------------------------|----------------------------------------------------------------------------------|
| <i>global-ipv6-address</i> | IPv6 address of the next hop. The next hop router should be the neighbor router. |
| <i>vrf vrf-name</i>        | The nexthop belongs to the specified VRF which must be the                       |

|               |                                                                            |
|---------------|----------------------------------------------------------------------------|
|               | configured IPv6 address family multi-protocol VRF.                         |
| <i>global</i> | The nexthop belongs to the global.                                         |
| <i>weight</i> | Weight of the next hop in the load balancing mode, in the range of 1 to 8. |

**Default****configuration**      None**Command mode**      Route map configuration mode

This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In the former mode, the system implements WCMP load balancing according to the weight entered by the user.

Multiple IP addresses may follow set ip next-hop and the number of addresses should be less than 32.

If weight follows ip address, up to 4 next hop addresses can be configured.

If the parameter vrf *vrf-name* is specified, packets forwarding will be across the VRF. The packets will be forwarded from VRF to public network with the parameter global specified. If no [vrf *vrf-name* | global] is specified, forwarding the IPv6 packets will inherit the VRF, that is the nexthop belongs to the VRF that receives this IPv6 packets.

**Usage guideline**

If weight follows any next-hop, the operation mode of this command will be automatically switched to the WCMP load balancing mode. In the WCMP load balancing mode, for the nexthop address without configuring the corresponding weight, the weight is 1 by default.

When the packets select the egress from the policy-based routing and routing table, the priorities are as follows.

```
set ipv6 next-hop;
usual route (the non default route)
set ipv6 default next-hop
Default route.
```

The following example sets the next hop of the packet with destination address

2001:0db8:2001:1760::/64 received at the interface fastEthernet 0/0 as 2002:0db8:2003:1::95

**Examples**

```
Ruijie(config)# ipv6 access-list acl_for_pbr
Ruijie(config-ipv6-acl)#permit ipv6 any 2001:0db8:2001:1760::/64
Ruijie(config)#route-map rm_if_0_0
Ruijie(config-route-map)#match ipv6 address acl_for_pbr
Ruijie(config-route-map)# set ipv6 next-hop
2002:0db8:2003:1::95
```

```
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ipv6 policy route-map rm_if_0_0
```

**Related  
commands**

| Command                      | Description                                    |
|------------------------------|------------------------------------------------|
| <b>match ipv6 address</b>    | Set the matching rule of policy-based routing. |
| <b>ipv6 policy route-map</b> | Use the policy-based routing on the interface. |
| <b>set ipv6 next-hop</b>     | Set the next hop of the policy-based routing.  |

**Platform**

**description** N/A

## 8.52 set ipv6 next-hop recursive

Use this command to specify the IPv6 address of a recursive next hop for packets matching the match rule.

Use the **no** form of this command to delete the IPv6 address of a recursive next hop.

**set ipv6 [ vrf *vrf-name* | global ] next-hop recursive *ipv6-address***

**no set ipv6 [ vrf *vrf-name* | global ] next-hop recursive**

**Parameter  
Description**

| Parameter                  | Description                                        |
|----------------------------|----------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i> | The next hop address belongs to the specified VRF. |
| <b>global</b>              | The next hop address belongs to the global.        |
| <i>ipv6-address</i>        | IPv6 address of a recursive next hop               |

**Defaults** N/A

**Command  
Mode**

Routing map configuration mode

**Default Level** 14

**Usage Guide**

This command is used only to configure PBR. Only one **set ip next-hop recursive *ip-address*** command can be configured in one routing sub map policy.

According to the policy, recursion is supported for only static or dynamic routes that have an egress and next-hop IPv6 address. A maximum of 32 recursive next hops are supported.

**Configuration**

**Example**

The following example sets the recursive next hop for packets with the destination address set to 2001:0db8:2001:1760::/64 and received from interface GigabitEthernet 0/0 to 2002:0db8:2003:1::95.

```
Ruijie(config)# ipv6 access-list acl_for_pbr
```

```

Ruijie(config -ipv6-acl)#permit ipv6 any 2001:0db8:2001:1760::/64
Ruijie(config)#route-map rm_if_0_0
Ruijie(config-route-map)#match ip address acl_for_pbr
Ruijie(config-route-map)# set ipv6 next-hop recursive 2002:0db8:2003:1::95
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if)#ipv6 policy route-map rm_if_0_0

```

**Verification** Run the **show running-config** command to display the configurations.

Run the **show ipv6 pbr route** command to display the next hop recursed to the static or dynamic route.

## 8.53 set ipv6 next-hop verify-availability

Use this command to determine the availability of the next-hop IP address.

**set ipv6 [ vrf vrf-name | global ] next-hop verify-availability ipv6-address [track track-obj-number | bfd interface-type interface-number gateway]**

Use the **no** form of this command to delete existing configuration.

**no set ip [ vrf vrf-name | global ] next-hop verify-availability ipv6-address [track track-obj-number | bfd interface-type interface-number gateway]**

### Parameter Description

| Parameter           | Description                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> vrf-name | The next hop address belongs to the specified VRF.                                                                                                                                             |
| <b>global</b>       | The next hop address belongs to the global.                                                                                                                                                    |
| ipv6-address        | Specifies the next-hop IPv6 address.                                                                                                                                                           |
| <b>track</b>        | Detects whether the next hop is effective by using the tracking method.                                                                                                                        |
| track-obj-number    | Specifies the tracking object number.                                                                                                                                                          |
| <b>bfd</b>          | Conducts neighbor detection by using BFD.                                                                                                                                                      |
| interface-type      | Specifies the interface type.                                                                                                                                                                  |
| interface-number    | Specifies the interface number.                                                                                                                                                                |
| gateway             | Specifies the gateway IPv6 address, that is, IPv6 address of the BFD neighbor. If the configured next hop is the neighbor, the availability of the forwarding path will be detected using BFD. |

**Defaults** N/A

**Command Mode** Routing map configuration mode

**Default Level** 14

**Usage Guide** This command is used only to configure PBR.

**Examples** The following example enables the PBR support for BFD and detects the forwarding path to the neighbor 2001:1::2 via BFD.

```
Ruijie(config)# route-map rmap permit 10
Ruijie(config-route-map)# set ipv6 next-hop verify-availability 2001:1::2 bfd
FastEthernet 0/1 2001:1::2
```

## 8.54 set ipv6 precedence

Use this command to set the precedence of the IPv6 head of the packet matching the rule in the route map configuration mode. Use the **no** form of this command to remove the configured precedence setting.

**set ipv6 precedence** {<0-7> | *critical* | *flash* | *flash-override* | *immediate* | *internet* | *network* | *priority* | *routine* }

**no set ipv6 precedence** {<0-7> | *critical* | *flash* | *flash-override* | *immediate* | *internet* | *network* | *priority* | *routine* }

| Parameter description | Parameter                                                                                                                                          | Description                           |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
|                       | <i>critical</i> , <i>flash</i> , <i>flash-override</i> , <i>immediate</i> ,<br><i>internet</i> , <i>network</i> , <i>priority</i> , <i>routine</i> | The precedence type of the IPv6 head. |
|                       | 0~7                                                                                                                                                | The configurable precedence range.    |

**Default configuration** N/A

**Command mode** Route map configuration mode

The following table shows the corresponding relationship between the value and type.

| Usage guideline | Value | Type           |
|-----------------|-------|----------------|
|                 | 0     | routing        |
|                 | 1     | priority       |
|                 | 2     | network        |
|                 | 3     | internet       |
|                 | 4     | immediate      |
|                 | 5     | flash-override |
|                 | 6     | flash          |
|                 | 7     | critical       |

**Examples** The following example sets the precedence of IPv6 packet head as 3:  
Configure the associated ACL6

```

Ruijie(config)#ipv6 access-list aaa
Ruijie(config-ipv6-acl)#permit ipv6 2003:1000::10/80 2001:100::/64
Configure route-map.
Ruijie(config)#route-map pbr-aaa permit 10
Ruijie(config-route-map)#set ipv6 next-hop 2001:1234::2
Modify the precedence.
Ruijie(config-route-map)# set ipv6 precedence 3
Or
Ruijie(config-route-map)# set ipv6 precedence immediate

```

**Related commands**

| Command                          | Description                                                 |
|----------------------------------|-------------------------------------------------------------|
| <b>match ipv6 address</b>        | Configure the ACL used for matching the packet in IPv6 PBR. |
| <b>route-map</b>                 | Use the route map of the policy-based routing.              |
| <b>set default interface</b>     | Set the default next-hop egress.                            |
| <b>set interface</b>             | Set the next hop egress.                                    |
| <b>set ipv6 default next-hop</b> | Set the default next-hop address for forwarding packets.    |
| <b>set ipv6 next-hop</b>         | Set the next-hop address for forwarding packet.             |
| <b>show ipv6 policy</b>          | Show the policy-based routing                               |
| <b>show route-map</b>            | Show the route map configuration.                           |

**Platform description**

N/A

## 8.55 set level

Use this command to set the level of the area where the routes matching the rule are redistributed in the route map configuration command. Use the **no** form of this command to remove the setting.

**set level {level-1 | level-2 | level-1-2 | stub-area | backbone}**

**no set level**

**Default configuration**

None

**Command mode**

Route map configuration mode

In the example below, the OSPF routing protocol redistributes the RIP protocol to the backbone area.

### Examples

```
Ruijie(config)# router ospf
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# set level backbone
```

### Related commands

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |
| <b>match metric</b>          | Match the metric.              |
| <b>match route-type</b>      | Match the route type.          |
| <b>match tag</b>             | Match the tag.                 |
| <b>set metric-type</b>       | Set the metric type.           |
| <b>set tag</b>               | Set the tag.                   |

## 8.56 set local-preference

Use this command to set the **LOCAL\_PREFERENCE** value for the routes to be redistributed in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set local-preference** *number*

**no set local-preference**

| Parameter          | Parameter     | Description                                   |
|--------------------|---------------|-----------------------------------------------|
| <b>description</b> | <i>number</i> | Local priority metric ranging 1 to 4294967295 |

### Default

**configuration** None

**Command mode** Route map configuration mode

### Usage guideline

Use this command to set the local preference for the matched routes. Only one local preference can be set.

**Examples**

```

Ruijie(config)# route-map SET_PREF permit 10
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set local-preference 6800
Ruijie(config-route-map)# exit
Ruijie(config)# route-map SET_PREF permit 20
Ruijie(config-route-map)# match as-path 2
Ruijie(config-route-map)# set local-preference 50

```

**Related commands**

| Command                    | Description                  |
|----------------------------|------------------------------|
| <b>match as-path</b>       | Match the AS_PATH attribute. |
| <b>match metric</b>        | Match the route metric.      |
| <b>match origin</b>        | Match the source.            |
| <b>set as-path prepend</b> | Set the AS_PATH attribute.   |
| <b>set metric</b>          | Set the metric.              |
| <b>set metric-type</b>     | Set the metric type.         |

## 8.57 set metric

Use **set metric** to set the metric for the routes to be redistributed. Use the **no** form of this command to remove the setting.

**set metric** [+ *metric-value* | - *metric-value* | *metric-value*]

**no set metric**

**Parameter description**

| Parameter           | Description                                        |
|---------------------|----------------------------------------------------|
| +                   | Increase based on the metric of the original route |
| -                   | Decrease based on the metric of the original route |
| <i>metric-value</i> | Metric for the route to be redistributed           |

**Default****configuration**

The default metric for route redistribution varies with the routing protocol.

**Command mode**

Route map configuration mode

You should set the metric according to the actual network topology, because the routing depends on the metric of routes. Attentions should be paid to the upper and lower limits of the routing protocols when you execute the `set metric`, `+ metric` or `- metric` commands. When the RIP protocol redistributes the routes of other protocols, the range of the metric after increase or decrease is 1 to 16.

#### Usage guideline

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more `match` or `set` commands can be executed to configure a route map. If the `match` command is not used, all the routes will be matched. If the `set` command is not used, no operation will be performed.

The following example enables the OSPF routing protocol to redistribute the RIP routes and sets the default metric to 40.

#### Examples

```
Ruijie(config)# router ospf
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# set metric 40
```

#### Related commands

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |
| <b>match metric</b>          | Match the metric.              |
| <b>match route-type</b>      | Match the route type.          |
| <b>match tag</b>             | Match the tag.                 |
| <b>set metric-type</b>       | Set the metric type.           |
| <b>set tag</b>               | Set the tag.                   |

## 8.58 set metric-type

Use **set metric-type** to set the type of the routes to be redistributed. Use the **no** form of this command to remove the setting.  
**set metric-type** *type*

**no set metric-type****Parameter  
description**

| Parameter   | Description                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i> | Type of the routes to be redistributed. At present, you can set the type of the routes that the OSPF protocol redistributes.<br>type-1: Type-1 external route;<br>type-2: Type-2 external route. |

**Default  
configuration**

Type-2

**Command mode**

Route map configuration mode

**Usage guideline**

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The following example enables the OSPF routing protocol to redistribute the RIP route and sets the type as type-1.

**Examples**

```
Ruijie(config)# router ospf
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# set metric-type type-1
```

**Related  
commands**

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |
| <b>match metric</b>          | Match the metric.              |
| <b>match route-type</b>      | Match the route type.          |
| <b>match tag</b>             | Match the tag.                 |
| <b>set metric</b>            | Set the metric.                |

|                |              |
|----------------|--------------|
| <b>set tag</b> | Set the tag. |
|----------------|--------------|

## 8.59 set next-hop

Use this command to specify the next-hop IP address for the routes that match the rule. Use the **no** form of this command to remove the setting. This command is only used to configure routing policies.

**set next-hop** *ip-address*

**no set next-hop**

| Parameter   | Parameter         | Description                 |
|-------------|-------------------|-----------------------------|
| description | <i>ip-address</i> | IP address of the next hop. |

### Default

**configuration** None

### Command

**mode** Route map configuration mode

### Usage guideline

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

### Examples

The following example enables the OSPF routing protocol to redistribute the RIP route and sets the next-hop to 192.168.1.2.

```
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# match ip address 1
Ruijie(config-route-map)# set next-hop 192.168.1.2
```

### Related commands

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |

|                         |                       |
|-------------------------|-----------------------|
| <b>match metric</b>     | Match the metric.     |
| <b>match route-type</b> | Match the route type. |
| <b>match tag</b>        | Match the tag.        |
| <b>set metric-type</b>  | Set the metric type.  |
| <b>set tag</b>          | Set the tag.          |

## 8.60 set origin

Use this command to set the source of the routes to be redistributed in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set origin {egp | igp | incomplete}**

**no set origin {egp | igp | incomplete}**

| Parameter  | Description                                     |
|------------|-------------------------------------------------|
| egp        | Redistribute the routes from the remote EGP.    |
| igp        | Redistribute the routes from the local IGP.     |
| incomplete | Redistribute the routes from an unknown device. |

**Default configuration**      None

**Command mode**      Route map configuration mode

**Usage guideline**      Use this command to set the source of the routes to be matched. Only one route source attribute can be set.

### Examples

```
Ruijie(config)# route-map SET_ORIGIN 10 permit
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set origin igp
Ruijie(config-route-map)# exit
Ruijie(config)# route-map SET_ORIGIN 20 permit
Ruijie(config-route-map)# match as-path 2
Ruijie(config-route-map)# set origin egp
```

| Command                    | Description                  |
|----------------------------|------------------------------|
| <b>match as-path</b>       | Match the AS_PATH attribute. |
| <b>match metric</b>        | Match the route metric.      |
| <b>match origin</b>        | Match the source.            |
| <b>set as-path prepend</b> | Set the AS_PATH attribute.   |

**Related commands**

|                             |                                                 |
|-----------------------------|-------------------------------------------------|
| <b>set metric</b>           | Set the metric.                                 |
| <b>set local-preference</b> | Set the local priority of redistributed routes. |

## 8.61 set originator-id

Use this command to set the source of the routes to be redistributed in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set originator-id** *ip-addr*

**no set originator-id** [*ip-addr*]

| Parameter          | Parameter      | Description                   |
|--------------------|----------------|-------------------------------|
| <b>description</b> | <i>ip-addr</i> | IP address of the originator. |

**Default configuration**      None

**Command mode**      Route map configuration mode

**Usage guideline**      Use this command to set the source of the routes to be matched.

### Examples

```
Ruijie(config)# route-map SET_ORIGIN 10 permit
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set originator-id 5.5.5.5
Ruijie(config-route-map)# exit
Ruijie(config)# route-map SET_ORIGIN 20 permit
Ruijie(config-route-map)# match as-path 2
Ruijie(config-route-map)# set originator-id 5.5.5.6
```

### Related commands

| Command                     | Description                                     |
|-----------------------------|-------------------------------------------------|
| <b>match as-path</b>        | Match the AS_PATH attribute.                    |
| <b>match metric</b>         | Match the route metric.                         |
| <b>match origin</b>         | Match the source.                               |
| <b>set as-path prepend</b>  | Set the AS_PATH attribute.                      |
| <b>set metric</b>           | Set the metric.                                 |
| <b>set local-preference</b> | Set the local priority of redistributed routes. |

## 8.62 set tag

Use this command to set the tag for the routes to be redistributed. Use the **no** form of this command to remove the setting.

**set tag** *tag*

**no set tag**

| Parameter   | Parameter  | Description                          |
|-------------|------------|--------------------------------------|
| description | <i>tag</i> | Tag of the route to be redistributed |

### Default

**configuration** The original routing tag remains unchanged.

**Command mode** Route map configuration mode

**Usage guideline** This command can only be used for route redistribution. If this command is not configured, the default route tag is used.

The following example enables the OSPF routing protocol to redistribute the RIP route and sets the tag as 100.

### Examples

```
Ruijie(config)# router ospf
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# set tag 100
```

### Related commands

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |
| <b>match metric</b>          | Match the metric.              |
| <b>match route-type</b>      | Match the route type.          |
| <b>match tag</b>             | Match the tag.                 |
| <b>set metric</b>            | Set the metric.                |
| <b>set metric-type</b>       | Set the metric type.           |

## 8.63 set weight

Use this command to set the weight for the BGP routes matching filtering rules. Use the **no** form of this command to remove the setting.

**set weight** *number*

**no set weight**

| Parameter   | Parameter     | Description                       |
|-------------|---------------|-----------------------------------|
| description | <i>number</i> | Weight in the range of 0 to 65535 |

**Default**  
**configuration**      None

**Command mode**      Route map configuration mode

**Usage guideline**

This command can only be used modify the weight of a BGP route.

By default, the weight of the route learned from a neighbor is the one configured with the neighbor weight command. The weight of the locally generated route is fixed 32768.

**Examples**

The following example sets the weight for the BGP route learned from the neighbor 1.1.1.1 at the inbound direction to 100.

```
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.1 route-map nei-rmap-in in
Ruijie(config-router)# exit
Ruijie(config)# route-map nei-rmap-in permit 10
Ruijie(config-route-map)# set weight 100
```

| Related commands | Command                | Description                                     |
|------------------|------------------------|-------------------------------------------------|
|                  | <b>match as-path</b>   | Match the AS_PATH attribute.                    |
|                  | <b>match community</b> | Match the route community.                      |
|                  | <b>match metric</b>    | Match the route metric.                         |
|                  | <b>match origin</b>    | Match the source.                               |
|                  | <b>set community</b>   | Set community of the redistributed route.       |
|                  | <b>set metric</b>      | Set the metric of the redistributed route.      |
|                  | <b>set metric type</b> | Set the metric type of the redistributed route. |

## 8.64 statement-name

Use this command to set the statement name of route map. Use the **no** form of this command to

remove the settings.

**statement-name** *name*

**no statement-name**

| Parameter<br>description | Parameter   | Description       |
|--------------------------|-------------|-------------------|
|                          | <i>name</i> | Name of statement |

**Default  
configuration**    None

**Command  
mode**            Route map configuration mode

**Usage**            The command is not a route policy command and does not apply to routing protocol.  
**guideline**        It only takes effect in OPENCONF YANG to record the statement name of route map.

**Examples**            The following example names the statement as sname

```
Ruijie(config)# route-map test
Ruijie(config-route-map)# statement-name sname
```

| Related<br>commands | Command | Description |

## 8.65 show ip as-path-access-list

Use this command to display the configuration of AS path access lists.

**show ip as-path-access-list** [ *num* ]

| Parameter<br>description | Parameter  | Description                 |
|--------------------------|------------|-----------------------------|
|                          | <i>num</i> | AS path access list number. |

**Default**            N/A

**Command  
mode**            Privileged EXEC mode

**Usage**            N/A

**guideline**

**Examples** The following example displays the AS path access lists.

```
Ruijie# show ip as-path-access-list
AS path access list 30
permit ^30$
```

| Field               | Description                                         |
|---------------------|-----------------------------------------------------|
| AS path access list | AS path access list number                          |
| permit              | Permits advertisement based on matching conditions. |
| ^30\$               | Regular expression.                                 |

| Related command | Command | Description |

## 8.66 show ip community-list

Use **show ip community-list** command to display the community list.

**show ip community-list** [*community-list-number* | *community-list-name*]

| Parameter description | Parameter                    | Description                   |
|-----------------------|------------------------------|-------------------------------|
|                       | <i>community-list-number</i> | Number of the community list. |
|                       | <i>community-list-name</i>   | Name of the community list.   |

**Default configuration** None

**Command mode** Privileged EXEC mode

**Usage guidelines** N/A

**Examples**

```
Ruijie# show ip community-list
Community-list standard local
permit local-AS
Community-list standard Red-Giant
permit 0:10
```

```
deny 0:20
```

**Related  
commands**

| Command              | Description                                       |
|----------------------|---------------------------------------------------|
| match community      | Match the route community.                        |
| set comm-list delete | Delete the community attribute in the BGP routes. |

## 8.67 show ip extcommunity-list

Use this command to display the extcommunity list.

**show ip extcommunity-list** [ *extcommunity-list-num* | *extcommunity-list-name* ]

**Parameter  
description**

| Parameter                     | Description                                      |
|-------------------------------|--------------------------------------------------|
| <i>extcommunity-list-num</i>  | extcommunity-list number, ranging from 1 to 199. |
| <i>extcommunity-list-name</i> | extcommunity-list name.                          |

**Default**

-

**Command mode**

Privileged EXEC mode.

**Usage guideline**

-

**Examples**

```
Ruijie # show ip extcommunity-list
Standard extended community-list 1
 10 permit RT:1:200
 20 permit RT:1:100
Standard extended community-list 2
 10 permit RT:1:200
Expanded extended community-list rt_filter
 13 permit 1:100
```

**Related command**

| Command                     | Description                  |
|-----------------------------|------------------------------|
| <b>ip extcommunity-list</b> | Create an extcommunity-list. |
| <b>match extcommunity</b>   | Match an extcommunity.       |
| <b>set extcommunity</b>     | Set an extcommunity.         |

**Platform description**

-

## 8.68 show ip prefix-list

Use **show ip prefix-list** to display the prefix list or the entries.

**show ip prefix-list** [*prefix-name*]

| Parameter   | Parameter          | Description              |
|-------------|--------------------|--------------------------|
| description | <i>prefix-name</i> | Name of the prefix list. |

### Default

**configuration** The configuration information of all the prefix lists is displayed by default.

**Command mode** Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode, route map configuration mode.

**Usage guidelines** If no prefix list is specified, the configurations of all the prefix lists are displayed, otherwise only the configuration of the specified prefix list is displayed.

### Examples

```
Ruijie# show ip prefix-list
ip prefix-list name : test
seq pre: 2 entries
seq 5 permit 192.168.564.0/24
seq 10 permit 192.2.2.0/24
```

## 8.69 show ip protocols

Use this command to display information about the status of the currently running IPv4 routing protocol.

**show ip protocols** [ *vrf vrf-name* ] { **bgp** | **isis** | **ospf** | **rip** }

| Parameter   | Parameter       | Description                                                                                                                                 |
|-------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>vrf-name</i> | Specifies the VRF instance name. If it is not specified, information about the status of routing protocols in global VRF mode is displayed. |
|             | <b>bgp</b>      | Displays information about the status of the BGP protocol.                                                                                  |
|             | <b>isis</b>     | Displays information about the status of the IS-IS protocol.                                                                                |
|             | <b>ospf</b>     | Displays information about the status of the OSPF protocol.                                                                                 |
|             | <b>rip</b>      | Displays information about the status of the RIP protocol.                                                                                  |
|             | -               | Displays information about the status of all running routing protocols.                                                                     |

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode, and routing map configuration mode

**Default Level** 14

**Usage Guide** Information about the status of only the currently running routing protocol is displayed, and the information about a routing protocol that is not running is not displayed.

**Examples** The following example displays the status of routing protocols running in global VRF mode.

```
Ruijie# show ip protocols
Routing Protocol is "ospf 1"
  Outgoing update filter list for all interfaces is not set
  Incoming update filter list for all interfaces is not set
  Router ID 57.57.57.57

## 8.70 show ipv6 prefix-list

Use this command to display the information about the IPv6 prefix list or its entries.

**show ipv6 prefix-list** [*prefix-name*]

| Parameter       | Parameter                                                                                                                                                             | Description                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| description     | <i>prefix-name</i>                                                                                                                                                    | Name of the IPv6 prefix list. |
| Default         | The configuration information of all the IPv6 prefix lists is displayed.                                                                                              |                               |
| configuration   |                                                                                                                                                                       |                               |
| Command mode    | Privileged EXEC mode, global configuration mode, interface configuration mode, route protocol configuration mode, route map configuration mode                        |                               |
| Usage guideline | If no prefix list is specified, the configurations of all the prefix lists are displayed, otherwise only the configuration of the specified prefix list is displayed. |                               |
| Examples        | <pre>Ruijie# show ipv6 prefix-list Ipv6 prefix-list p6 : 2 entries permit 13::/20</pre>                                                                               |                               |

## 8.71 show key chain

Use this command to display the key chain configuration.

**show key chain** [*key-chain-name*]

| Parameter description | Parameter             | Description                                                      |
|-----------------------|-----------------------|------------------------------------------------------------------|
|                       | <i>key-chain-name</i> | (Optional) Display the configuration of the specified key chain. |

**Default** The configuration information of all key chains is displayed.

**Command mode** Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode, and key chain configuration mode.

**Usage guideline** If no key chain is specified, the configuration information of all key chains is displayed.

**Examples**

```
Ruijie# sh key chain
key chain ripkeys
  key 1 -- text "abc"
  accept-lifetime (00:00:00 Sep 09 2000) - (00:00:00 Dec 12 2011)
  send-lifetime (00:00:00 Sep 09 2000) - (00:00:00 Dec 12 2011)
```

| Field           | Description                       |
|-----------------|-----------------------------------|
| key chain       | Key chain name.                   |
| key             | Key ID.                           |
| text            | Key string.                       |
| accept-lifetime | Lifetime in the accept direction. |
| send-lifetime   | Lifetime in the send direction.   |

**Related command**

## 8.72 show route-map

Use the command to display the configuration of the route map.

**show route-map** [*route-map-name*]

**Parameter description**

| Parameter             | Description                                                                      |
|-----------------------|----------------------------------------------------------------------------------|
| <i>route-map-name</i> | (Optional) Display the configuration information of the specified the route map. |

**Default****configuration**

The configuration information of all the route maps is displayed.

**Command mode**

Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode, route map configuration mode.

**Usage guidelines**

If no route map is specified, the configurations of all the route maps will be displayed, otherwise only the configuration of the specified route map is displayed.

```
Ruijie# show route-map
route-map AAA, permit, sequence 10
Match clauses:
ip address 2
Set clauses:
metric 10
```

**Examples**

| Field         | Description                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------|
| route-map     | Name of the route map.                                                                                              |
| Permit        | The route map contains the permit keyword.                                                                          |
| sequence 10   | Sequence number of the route map.                                                                                   |
| Match clauses | Set the matching rule. Whether to perform the set operation depends on the permit or deny keyword in the route map. |
| Set clauses   | Set the operation when the rule is matched.                                                                         |

## 9 PBR Commands

### 9.1 clear ip pbr statistics

Use this command to clear the IPv4 PBR forwarded packet count.

**clear ip pbr statistics** [ **interface** *if-name* | **local** ]

| Parameter<br>Description | Parameter                       | Description                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <b>interface</b> <i>if-name</i> | Specifies the interface name. If the interface name is specified, the device clears the IPv4 PBR forwarded packet count on that interface. Otherwise, the device clears the IPv4 PBR forwarded packet count on every interface where IPv4 PBR is enabled. |
|                          | <b>local</b>                    | Clears the IPv4 PBR forwarded packet count on the local interface.                                                                                                                                                                                        |
|                          |                                 |                                                                                                                                                                                                                                                           |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** Use this command to clear the IPv4 PBR forwarded packet count.

**Configuration** The following example clears the IPv4 PBR forwarded packet count.

**Examples** Ruijie#clear ip pbr statistics

**Description**

## 9.3 ip local policy route-map

Use this command to apply the policy-based routing ( PBR ) on the packets sent locally. Use the **no** form of this command to restore the default setting.

**ip local policy route-map** *route-map*

**no ip local policy route-map**

| <b>Parameter Description</b> | Parameter        | Description           |
|------------------------------|------------------|-----------------------|
|                              | <i>route-map</i> | Name of the route map |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is valid for the IP packets sent locally, but not the IP packets received locally. The IP

packets received by the local are free from this command.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

The **set interface** command for the policy-based routing does not support the load-balancing and only supports the redundancy backup.

**Configuration** The following examples send the packets with the source address 192.168.217.10 from the serial 2/0.

**Examples** The following example defines an ACL that match the IP packet.

```
Ruijie(config)#access-list 1 permit 192.168.217.10
```

The following example defines the route map.

```
Ruijie(config)#route-map lab1 permit 10
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set interface serial 2/0
Ruijie(config-route-map)#exit
```

The following example applies PBR on the local interface.

```
Ruijie(config)#ip local policy route-map lab1
```

#### Related Commands

| Command                        | Description                                               |
|--------------------------------|-----------------------------------------------------------|
| <b>access-list</b>             | Defines the access list rule.                             |
| <b>route-map</b>               | Defines the route map.                                    |
| <b>set vrf</b>                 | Defines the VRF instance of the policy-based IP packet.   |
| <b>set ip next-hop</b>         | Defines the next hop of the policy-based routing.         |
| <b>set ip default next-hop</b> | Defines the default next hop of the policy-based routing. |
| <b>set interface</b>           | Defines the output port of the policy-based routing.      |
| <b>set default interface</b>   | Defines the default policy-based routing output port.     |
| <b>set ip tos</b>              | Sets the TOS in the head of the IP packet.                |
| <b>set ip dscp</b>             | Sets the DSCP of the IP packet.                           |
| <b>set ip precedence</b>       | Sets the priority level in the head of the IP packet.     |
| <b>match ip address</b>        | Sets the filtering rule.                                  |

|                     |                            |
|---------------------|----------------------------|
| <b>match length</b> | Matches the packet length. |
|---------------------|----------------------------|

**Platform** N/A

**Description**

## 9.4 ip policy-source in-interface

Use this command to configure the source address policy-based routing for the IPv4 packets received on an interface. Use the **no** form of this command to disable the source address policy-based routing on the interface.

**ip policy-source in-interface** *interface-type* *sequence* { *source-address mask* | *source-address/mask* } **[default]** **next-hop** *ip-address* [*weight*] }

**no ip policy-source in-interface** *interface-type* *sequence* [ {*source-address mask* | *source-address/mask* } [ **[default]** **next-hop** *ip-address* [*weight*]]

**Parameter Description**

| Parameter             | Description                                                                  |
|-----------------------|------------------------------------------------------------------------------|
| <i>interface-type</i> | Interface type                                                               |
| <i>sequence</i>       | Policy sequence number. The lower the number is, the higher the priority is. |
| <i>source-address</i> | Source IPv4 address.                                                         |
| <i>mask</i>           | Address mask.                                                                |
| <i>ip-address</i>     | Next hop IPv4 address                                                        |
| <i>weight</i>         | Next hop weight                                                              |

**Defaults** Source address policy-based routing is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** You can configure multiple **ip policy-source in-interface** commands on an interface. The policy with different source addresses must be configured with different sequence numbers. The lower the sequence number is, the higher the priority is.

In case of the same sequence number, the priority order of the next hop type is as follows:

**vrf** *vrf-name* > **next-hop** *ip-address* > **interface** *out-interface-type* > **default next-hop** *ip-address* > **default interface** *out-interface-type*

The priority of the source address PBR is lower than that of the interface PBR.

**Configuration Examples** In the example below, when the interface GigabitEthernet0/0 receives a datagram, if the source address of the datagram is 10.0.0.2, the next-hop is set as 196.168.1.2; otherwise, the general forwarding will be performed.

The following example configures source address PBR in global configuration mode.

```
Ruijie(config)# ip policy-source in-interface gigabitEthernet 0/0 1 10.0.0.2 255.255.255.255
next-hop 196.168.1.2
Ruijie(config)# ip policy-source in-interface gigabitEthernet 0/0 2 20.0.0.2
255.255.255.255 next-hop 196.168.2.2
```

## 9.5 ip policy

Use this command to set the policy: redundant backup or load balancing used between multiple next hops of the PBR applied for the **set ip [ default ] nexthop** command in global configuration mode.

Use the **no** form of this command to restore the default setting.

**ip policy { load-balance | redundancy }**

**no ip policy**

#### Parameter Description

| Parameter                        | Description                                               |
|----------------------------------|-----------------------------------------------------------|
| <b>load-balance   redundancy</b> | Specifies the policy: load balancing or redundant backup. |

#### Defaults

Redundant backup is adopted by default.

#### Command Mode

Global configuration mode

#### Usage Guide

When you configure the **set ip next-hop** command in sub-route map, it is possible to configure multiple next hops. However, when you set redundant backup, only the first resolved next hop of the policy-based routing takes effect. When the load balancing is set, multiple resolved next hops of the policy-based routing take effect. The WCMP can be set up to 8 next hops, and the ECMP can be set up to 32 next hops. The resolved next hop refers to the ARP message learned by the next hop and the MAC address corresponding to this ARP exists in the MAC address table.

NPE80 does not support this command.

#### Configuration

In the example below, there are multiple next hops configured in the route map. After the redundant

**Examples**

backup is set in global configuration mode, only the first next hop among the sub-route map of the policy-based routing applied on the interface FastEthernet 0/0 takes effect.

The following example sets the ACL that match the IP packet.

```
Ruijie(config)#access-list 1 permit 10.0.0.1
Ruijie(config)#access-list 2 permit 20.0.0.1
```

The following example defines the route map.

```
Ruijie(config)#route-map lab1 permit 10
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip next-hop 196.168.4.6
Ruijie(config-route-map)#set ip next-hop 196.168.4.7
Ruijie(config-route-map)#set ip next-hop 196.168.4.8
Ruijie(config-route-map)#exit
Ruijie(config)#route-map lab1 permit 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set ip next-hop 196.168.5.6
Ruijie(config-route-map)#set ip next-hop 196.168.5.7
Ruijie(config-route-map)#set ip next-hop 196.168.5.8
Ruijie(config-route-map)#exit
```

The following example applies the policy-based routing on the interface.

```
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ip policy route-map lab1
Ruijie(config-if)#exit
Ruijie(config)#ip policy redundancy
```

**Description**

## 9.6 ip policy route-map

Use this command to apply the policy-based routing on an interface. Use the **no** form of this command to restore the default setting.

**ip policy route-map** *route-map*

**no ip policy route-map**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                  |                       |
|------------------|-----------------------|
| <i>route-map</i> | Name of the route map |
|------------------|-----------------------|

**Defaults** This function is disabled by default.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** The policy-based routing must be applied on the specified interface. That interface performs the policy-based routing only on the received packets.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

 Up to one route map can be configured on an interface. When you configure a route map on the interface for many times, the latter will overwrite the former.

**Configuration Examples** In the example below, when the interface FastEthernet0/0 receives a datagram, if the source address of the datagram is 10.0.0.1, it sets the next-hop as 196.168.4.6; if the source address is 20.0.0.1, it sets the next-hop as 196.168.5.6; otherwise, the general forwarding will be performed.

The following example sets the ACL matched with the IP packets.

```
Ruijie(config)#access-list 1 permit 10.0.0.1
Ruijie(config)#access-list 2 permit 20.0.0.1
```

The following example defines the route map.

```
Ruijie(config)#route-map lab1 permit 10
Ruijie (config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip next-hop 196.168.4.6
Ruijie(config-route-map)#exit
Ruijie(config)#route-map lab1 permit 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set ip next-hop 196.168.5.6
Ruijie(config-route-map)#exit
```

The following example applies the route map on the interface.

```
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ip policy route-map lab1
Ruijie(config-if)#exit
```

## 9.7 ipv6 local policy route-map

Use this command to enable the policy-based routing on the packets sent locally. Use the **no** form of this command to restore the default setting.

**ipv6 local policy route-map** *route-map-name*

**no ipv6 local policy route-map**

**Parameter  
Description**

| Parameter             | Description                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------|
| <i>route-map-name</i> | Name of the router map applied locally, which is configured by the <b>router-map</b> command. |

**Defaults** This function is disabled by default.**Command  
Mode** Global Configuration mode**Usage Guide**

- This command is valid only for the IPv6 packets in accordance with the policy (for example, ping

packets used for management) sent locally, but not the packets received locally.

- To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

**Configuration** The following examples displays the PBR application process: The device sends the packets from the source address 2003:1000::10/80 to the 2001:100::/64, the packets will match ACL6 of aaa and be sent to the device 2003:1001::2.

#### Examples

- The following example defines the ACL matched with the IPv6 packet:

```
Ruijie(config)#ipv6 access-list aaa
Ruijie(config)#permit ipv6 2003:1000::10/80 2001:100::/64
```

- The following example defines the router map.

```
Ruijie(config)#route-map pbr-aaa permit 10
Ruijie(config-route-map)#match ipv6 address aaa
Ruijie(config-route-map)#set ipv6 next-hop 2003::1001::2
```

- The following example applies the PBR on the device.

```
Ruijie(config)#ipv6 local policy route-map pbr-aaa
```

| <b>set ipv6 default next-hop</b> | Sets the default next hop of packet forwarding.               |
| <b>set ipv6 next-hop</b>         | Sets the next hop of packet forwarding.                       |
| <b>set ipv6 precedence</b>       | Sets the priority field in the head of IPv6 packets.          |
| <b>show ipv6 policy</b>          | Displays the current PBR application.                         |
| <b>show route-map</b>            | Displays the current router map configuration.                |

**Platform** N/A

**Description**

## 9.8 ipv6 policy

Use this command to set the policy: redundant backup or load balancing, applied for the **set ip nexthop** command in global configuration mode. Use the **no** form of this command to restore the default setting.

**ipv6 policy { load-balance | redundancy }**

**no ipv6 policy**

**Parameter  
Description**

| Parameter           | Description                          |
|---------------------|--------------------------------------|
| <b>load-balance</b> | Sets the policy as load balancing.   |
| <b>redundance</b>   | Sets the policy as redundant backup. |

**Defaults** Redundant backup is adopted by default.

**Command  
Mode** Global configuration mode

**Usage Guide** This command is valid for the IP packets sent locally, but not the IP packets received locally. The IP packets received by the local are free from this command.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

The **set interface** command for the policy-based routing does not support the load-balancing and only supports the redundancy backup.

**Configuration** This function is valid for the multiple next-hops.

**Examples** When you configure the set ip next-hop command in sub-route map, it is possible to configure multiple next hops. However, when you set redundant backup, only the first resolved next hop takes effect. The second configured next hop will take effect only when the first one fails and the first next hop will take effect again if it recovers.

When the load balancing is set, multiple next hops of the policy-based routing take effect.

The WCMP can be set up to 8 next hops, and the ECMP can be set up to 32 next hops.

 The resolved next hop refers to the learned MAC address for the next-hop.

The following example sets load-balancing mode for multiple nexthops.

The following example configures an ACL matching with IP packets.

```
Ruijie(config)# ipv6 access-list 1
Ruijie(config-ipv6-acl )# permit ipv6 1000::1 any
Ruijie(config)# ipv6 access-list 2
Ruijie(config-ipv6-acl )# permit ipv6 2000::1 any
```

The following example defines a route map.

```
Ruijie(config)# route-map lab1 permit 10
Ruijie(config-route-map)# match ipv6 address 1
Ruijie(config-route-map)# set ipv6 next-hop 2002::1
Ruijie(config-route-map)# set ipv6 next-hop 2002::2
Ruijie(config-route-map)# set ipv6 next-hop 2002::3
Ruijie(config-route-map)# exit
Ruijie(config)# route-map lab1 permit 20
Ruijie(config-route-map)# match ipv6 address 2
Ruijie(config-route-map)# set ipv6 next-hop 2002::5
Ruijie(config-route-map)# set ipv6 next-hop 2002::6
Ruijie(config-route-map)# set ipv6 next-hop 2002::7
Ruijie(config-route-map)# exit
```

The following example applies policy-based routing on the interface.

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ipv6 policy route-map lab1
Ruijie(config-if)# exit
Ruijie(config)# ipv6 policy load-balance
```

**Description**

## 9.9 ipv6 policy route-map

Use this command to apply the policy-based routing on an interface in interface configuration mode.

Use the **no** form of this command to restore the default setting.

**ipv6 policy route-map** *route-map-name*

**no ip policy route-map****Parameter  
Description**

| Parameter             | Description                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------------------|
| <i>route-map-name</i> | Name of the PBR router map applied locally, which is configured by the <b>router-map</b> command. |

**Defaults**

This function is disabled by default..

**Command  
Mode**

Interface configuration mode

**Usage Guide**

The policy-based routing must be applied on the specified interface. That interface performs the policy-based routing only on the received packets.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

Up to one route map can be configured on an interface. When you configure a route map on the interface for many times, the latter will overwrite the former.

**Configuration**

An IPv6 packet is received on the fastEthernet 0/0. If the packet is sent from 10::/64 network

**Examples**

segment, it is forwarded to the next hop of 2000:1; if the packet is sent from 20::/64 network segment, it is forwarded to the next hop of 2000:2 or forwarded as usual.:

The following example configures an ACL matched with the IP packet.

```
Ruijie(config)# ipv6 access-list acl_for_pbr1
Ruijie (config-ipv6-acl)# permit ipv6 10::/64 any
Ruijie(config)# ipv6 access-list acl_for_pbr2
Ruijie (config-ipv6-acl)# permit ipv6 20::/64 any
```

The following example defines a route map.

```
Ruijie(config)# route-map rm_pbr permit 10
Ruijie (config-route-map)# match ipv6 address acl_for_pbr1
Ruijie(config-route-map)# set ipv6 next-hop 2000::1
Ruijie(config-route-map)# exit
Ruijie(config)# route-map rm_pbr permit 20
Ruijie(config-route-map)# match ipv6 address acl_for_pbr2
Ruijie(config-route-map)# set ipv6 next-hop 2000::2
Ruijie(config-route-map)# exit
```

The following example applies the route map to the interface.

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# no switchport
Ruijie(config-if)# ipv6 policy route-map rm_pbr
Ruijie(config-if)# exit
```

**Related

| <b>show route-map</b>            | Displays the current route map configurations.                    |

**Platform** N/A

**Description**

## 9.10 ipv6 policy-source in-interface

Use this command to configure the source address policy-based routing for the IPv6 packets received on an interface. Use the **no** form of this command to disable the source address policy-based routing on the interface.

**ipv6 policy-source in-interface** *interface-type* *sequence* *source-address/prefix-length* {[**default**] **next-hop** *ipv6-address* [*weight*] }

**no ipv6 policy-source in-interface** *interface-type* *sequence* [ *source-address/prefix-length* [ [**default**] **next-hop** *ipv6-address* [*weight*] ]

**Parameter  
Description**

| Parameter             | Description                                                                  |
|-----------------------|------------------------------------------------------------------------------|
| <i>interface-type</i> | Interface type                                                               |
| <i>sequence</i>       | Policy sequence number. The lower the number is, the higher the priority is. |
| <i>source-address</i> | Source IPv6 address.                                                         |
| <i>prefix-length</i>  | Prefix length of the source IPv6 address.                                    |
| <i>ipv6-address</i>   | Next hop IPv6 address                                                        |
| <i>weight</i>         | Next hop weight                                                              |

**Defaults** Source address PBR is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** You can configure multiple **ipv6 policy-source in-interface** commands on an interface. The policy with different source addresses must be configured with different sequence numbers. The lower the sequence number is, the higher the priority is.

In case of the same sequence number, the priority order of the next hop type is as follows:

```
vrf vrf-name > next-hop ipv6-address > interface out-interface-type > default next-hop  
ipv6-address > default interface out-interface-type
```

The priority of the source address PBR is lower than that of the interface PBR.

**Configuration Examples** In the example below, when the interface GigabitEthernet0/0 receives an IPv6 datagram, if the source address of the datagram is in the network segment of 10::/64, the next-hop is set as 2000:1; if the source address of the datagram is in the network segment of 20::/64, the next-hop is set as 2000:2; otherwise, the general forwarding will be performed.

The following example configures source address PBR in global configuration mode.

```
Ruijie(config)# ipv6 source-policy in-interface gigabitEthernet 0/0 2 10::/64  
next-hop 2000::1  
Ruijie(config)# ipv6 source-policy in-interface gigabitEthernet 0/0 2 20::/64  
next-hop 2000::2
```

| Parameter                       | Description                                                                                                                                                                                                                  |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface</b> <i>if-name</i> | Specifies the interface name. If the interface name is specified, the IPv4 BPR information of this interface is displayed. Otherwise, the IPv4 BPR information of all interfaces where the IPv4 PBR is enabled is displayed. |
| <b>local</b>                    | Displays the IPv4 PBR information on the local interface                                                                                                                                                                     |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to display the IPv4 PBR information.

**Configuration** The following example displays the IPv4 PBR information on the interfaces.

**Examples**

```
Ruijie#show ip pbr route
PBR IPv4 Route Summay : 1
Interface      : GigabitEthernet 0/1
  Sequence     : 10
  ACL[0]       : 2900
ACL_CLS[0]     : 0
  Min Length   : None
  Max Length   : None
  VRF ID       : 0
  Route Flags  :
  Route Type   : PBR
  Direct       : Permit
  Priority      : High
  Tos_Dscp     : None
  Precedence   : None
  Tos_Dscp     : 0
  Precedence   : 0
  Mode         : redundance
  Nexthop Count : 1
  Nexthop[0]   : 192.168.8.100
  Weight[0]    : 1
  Ifindex[0]   : 2
```

| Parameter             | Description                                                       |
|-----------------------|-------------------------------------------------------------------|
| PBR IPv4 Route Summay | IPv4 PBR route count.                                             |
| Interface             | Interface where IPv4 PBR is enabled.                              |
| Sequence              | The PBR serial number.                                            |
| ACL                   | The ACL ID used in the match rule.                                |
| ACL_CLS               | The ACL type used in the match rule, such as the IP standard ACL. |
| Min Length            | The minimum match length.                                         |
| Max Length            | The maximum match length.                                         |
| VRF ID                | Port-correlated VRF ID.                                           |

|               |                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Route Flags   | PBR flag bit:<br>Route Type: “PBR” indicates PBR routes.<br>“Normal” indicates common routes.<br>Direct: PBR matching action, <b>permit</b> or <b>deny</b><br>Priority: PBR priority, <b>High</b> or <b>Low</b><br>Tos_Dscp: Displays whether the <b>tos</b> rule or the <b>dscp</b> rule is configured.<br>Precedence: Displays whether the <b>set ip precedence</b> rule is configured. |
| Mode          | Specifies the redundancy mode or the next hop load balancing mode.                                                                                                                                                                                                                                                                                                                        |
| Nexthop Count | Specifies the next hop number. ECMP supports up to 32 next hops.                                                                                                                                                                                                                                                                                                                          |
| Nexthop       | Specifies the next hop IP address.                                                                                                                                                                                                                                                                                                                                                        |
| Weight        | Specifies the next hop weight.                                                                                                                                                                                                                                                                                                                                                            |
| Ifindex       | Specifies the outbound interface index corresponding to the next hop.                                                                                                                                                                                                                                                                                                                     |

## 9.13 show ip pbr route-map

Use this command to display the IPv4 PBR route-map information.

**show ip pbr route-map** *route-map-name*

**Parameter  
Description**

| Parameter             | Description         |
|-----------------------|---------------------|
| <i>route-map-name</i> | The route-map name. |

**Defaults**

N/A

**Command  
Mode**

Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv4 PBR route-map information.

**Examples**

```
Ruijie#show ip pbr route-map rm
Pbr VRF: GLOBAL, ID: 0
  Forward Mode: redundance
  Forwarding: On

route-map rm
  route-map index: sequence 10, permit
  Match rule:
    ACL ID :      0, ACL CLS: 0, Name: acl1
  Set rule:
    IPv4 Nexthop: 192.168.8.100, (VRF Name: , ID: 0), Weight: 0, Flags: 0
    PBR state info ifx: GigabitEthernet 0/1, Connected: true, Track State:
valid, Flags: 0
```

| Field           | Description                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------|
| Pbr VRF         | VRF name and VRF ID.                                                                         |
| Forward Mode    | Sets the load balance mode or the redundancy mode for the next hop.                          |
| Forwarding      | Displays whether the IP route forwarding is enabled.                                         |
| Route-map index | The serial number and the type of the sub-map.                                               |
| Match rule      | Match rule.                                                                                  |
| Set rule        | Set rule.                                                                                    |
| PBR state info  | PBR private data information, such as outbound interface and the link state of the next hop. |

**Description**

## 9.14 show ip pbr source-route

Use this command to display information about IPv4 source address-based PBR.

**show ip pbr source-route [ interface *if-name* ]**

| Parameter Description | Parameter                       | Description                                                                                                                                                             |
|-----------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>interface</b> <i>if-name</i> | Displays the IPv4 PBR applied to a specified interface if <i>if-name</i> is specified.<br>Displays all applied IPv4 PBR information if <i>if-name</i> is not specified. |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** You can use this command to display the configured source address-based PBR.

**Configuration Examples** The following example displays information about the configured source address-based PBR.

```
Ruijie# show ip pbr source-route
PBR IPv4 Source Route
Interface      : GigabitEthernet 0/1
Sequence      : 10
Source address : 10.1.1.1/24
VRF ID        : 0
Route Flags    :
Route Type     : PBR
Direct        : Permit
Priority       : High
Match_ipaddr   : Exist
Mode          : redundancy
Nexthop Count  : 1
Nexthop[0]    : 192.168.8.100
Weight[0]     : 1
Ifindex[0]    : 2
```

Field description:

| Field       | Description                                                          |
|-------------|----------------------------------------------------------------------|
| Interface   | Interface to which the PBR is applied                                |
| Sequence    | Sequence number of the PBR                                           |
| VRF ID      | ID of the VRF table associated with an interface                     |
| Route Flags | Flag bit of PBR:<br>Route Type: type of routes. The value <b>PBR</b> |

|               |                                                                                                                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p>indicates PBR routes while the value <b>Normal</b> indicates common routes.</p> <p>Direct: PBR matching mode. The options include <b>permit</b> and <b>deny</b>.</p> <p>Priority: priority of a PBR route. The options include <b>High</b> and <b>Low</b>.</p> |
| Mode          | Sets the next hop to work in redundancy mode or load balancing mode.                                                                                                                                                                                              |
| Nexthop Count | Sets the number of next hops. ECMP supports a maximum of 32 next hops.                                                                                                                                                                                            |
| Nexthop       | Sets the next-hop IPv4 address.                                                                                                                                                                                                                                   |
| Weight        | Sets the next-hop weight value.                                                                                                                                                                                                                                   |
| Ifindex       | Sets the outbound interface index of the next hop.                                                                                                                                                                                                                |

## 9.15 show ip pbr statistics

Use this command to display the IPv4 PBR forwarded packet count.

**show ip pbr statistics** [ **interface** *if-name* | **local** ]

### Parameter Description

| Parameter                       | Description                                                                                                                                                                                                                                        |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface</b> <i>if-name</i> | Specifies the interface name. If the interface name is specified, the IPv4 PBR forwarded packet count of this interface is displayed. Otherwise, the IPv4 PBR forwarded packet count of all interfaces where the IPv4 PBR is enabled is displayed. |
| <b>local</b>                    | Displays the IPv4 PBR forwarded packet count on the local interface.                                                                                                                                                                               |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv4 PBR forwarded packet count.

### Examples

```
Ruijie#show ip pbr statistics
IPv4 Policy-based route statistic
gigabitEthernet 0/1
statistics : 10
```

**Description**

## 9.16 show ip policy

Use this command to display the interface configured with the policy-based routing and the name of route map applied on the interface.

**show ip policy** [ *route-map-name* ]

| Parameter<br>Description | Parameter             | Description                                            |
|--------------------------|-----------------------|--------------------------------------------------------|
|                          | <i>route-map-name</i> | Specifies a route map to be applied on the interfaces. |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** You can use this command to verify the current PBR configured in the system.

**Configuration** The following example displays the current PBR configured in the system.

### Examples

```
Ruijie#show ip policy
Banalance Mode: redundance
Interface          Route map
local              test
FastEthernet 0/0   test
```

|---------------------|----------------------------------|----------------------------------------------------------|
|                     | <b>ip policy route-map</b>       | Applies the policy-based routing on the interface.       |
|                     | <b>ip local policy route-map</b> | Applies the policy-based routing on the local interface. |

**Platform** N/A

**Description**

## 9.17 show ipv6 pbr bfd

Use this command to display the correlation between the IPv6 policy router and BFD.

**show ipv6 pbr bfd**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the correlation between the IPv6 policy router and BFD.

**Examples**

```
Ruijie# show ipv6 pbr bfd
```

| VRF ID | Ifindex | Host      | State | Refcnt |
|--------|---------|-----------|-------|--------|
| 0      | 13      | 2000: : 2 | Up    | 1      |

Field Description

| Field   | Description                                                            |
|---------|------------------------------------------------------------------------|
| VRF ID  | VRF of BFD neighbors correlated with the policy router                 |
| Ifindex | The interface index of BFD neighbors correlated with the policy router |
| Host    | The peer IPv6 address                                                  |
| State   | Up/Down status of BFD neighbors correlated with the policy router      |
| Refcnt  | Calculation referred by BFD neighbors                                  |

## 9.18 show ipv6 pbr route

Use this command to display the IPv6 PBR information on the interface.

**show ipv6 pbr route** [ **interface** *if-name* | **local** ]

| Parameter<br>Description | Parameter                       | Description                                                                                                                                                                                                                  |
|--------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <b>interface</b> <i>if-name</i> | Specifies the interface name. If the interface name is specified, the IPv6 BPR information of this interface is displayed. Otherwise, the IPv6 BPR information of all interfaces where the IPv6 PBR is enabled is displayed. |
|                          | <b>local</b>                    | Displays the IPv6 PBR information on the local interface.                                                                                                                                                                    |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv6 PBR information on the interfaces.

**Examples**

```
Ruijie#show ipv6 pbr route
PBR IPv6 Route Summary : 1
Interface      : GigabitEthernet 0/2
  Sequence    : 10
  ACL[0]      : 2901

```

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PBR IPv4 Route Summay | IPv4 PBR route count.                                                                                                                                                                                                                                                                                                                                                                                                 |
| Interface             | Interface where IPv4 PBR is enabled.                                                                                                                                                                                                                                                                                                                                                                                  |
| Sequence              | The PBR serial number.                                                                                                                                                                                                                                                                                                                                                                                                |
| ACL                   | The ACL ID used in the match rule.                                                                                                                                                                                                                                                                                                                                                                                    |
| ACL_CLS               | The ACL type used in the match rule, such as the IP standard ACL.                                                                                                                                                                                                                                                                                                                                                     |
| Min Length            | The minimum match length.                                                                                                                                                                                                                                                                                                                                                                                             |
| Max Length            | The maximum match length.                                                                                                                                                                                                                                                                                                                                                                                             |
| VRF ID                | Port associated VRF ID.                                                                                                                                                                                                                                                                                                                                                                                               |
| Route Flags           | <p>PBR flag bit:</p> <p>Route Type: "PBR" indicates PBR routes.<br/>"Normal" indicates common routes.</p> <p>Direct: PBR matching action, <b>permit</b> or <b>deny</b></p> <p>Priority: PBR priority, <b>High</b> or <b>Low</b></p> <p>Tos_Dscp: Displays whether the <b>tos</b> rule or the <b>dscp</b> rule is configured.</p> <p>Precedence: Displays whether the <b>set ip precedence</b> rule is configured.</p> |
| Mode                  | Specifies the redundancy mode or the load balance mode for the next hop.                                                                                                                                                                                                                                                                                                                                              |
| Nexthop Count         | Specifies the next hop number. ECMP supports up to 32 next hops.                                                                                                                                                                                                                                                                                                                                                      |
| Nexthop               | Specifies the next hop IP address.                                                                                                                                                                                                                                                                                                                                                                                    |
| Weight                | Specifies the next hop weight.                                                                                                                                                                                                                                                                                                                                                                                        |
| Ifindex               | Specifies the outbound interface index corresponding to the next hop                                                                                                                                                                                                                                                                                                                                                  |

## 9.19 show ipv6 pbr route-map

Use this command to display the IPv6 PBR route-map information.

**show ipv6 pbr route-map** *route-map-name*

| Parameter   | Parameter             | Description         |
|-------------|-----------------------|---------------------|
| Description | <i>route-map-name</i> | The route-map name. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv6 PBR route-map information.

**Examples**

```
Ruijie#show ipv6 pbr route-map rm6
Pbr VRF: GLOBAL, ID: 0
Forward Mode: redundance
Forwarding: On

route-map rm6
route-map index: sequence 10, permit
Match rule:
ACL ID :      0, ACL CLS: 0, Name: acl6
Set rule:
IPv6 Nexthop: 10::1, (VRF Name: , ID: 0), Weight: 0, Flags: 0
PBR state info ifx: GigabitEthernet 0/0, Connected: true, Track State:
valid, Flags: 0
```

## 9.20 show ipv6 pbr source-route

Use this command to display the IPv6 source address PBR configuration.

**show ipv6 pbr source-route** [ **interface** *if-name* ]

**Parameter  
Description**

| Parameter                       | Description                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface</b> <i>if-name</i> | Displays the IPv6 source address PBR configuration on the specified interface.<br><br>If the parameter is not configured, the IPv6 source address PBR configuration on all interfaces will be displayed. |

**Defaults** N/A**Command  
Mode** Privileged EXEC mode**Usage Guide** N/A**Configuration** The following example displays the IPv6 source address PBR configuration.**Examples**

```
Ruijie# show ipv6 pbr source-route
PBR IPv6 Source Route
Interface      : GigabitEthernet 0/1
Sequence      : 10
Source address : 1000::1/64
VRF ID        : 0
Route Flags    :
Route Type     : PBR
Direct        : Permit
Priority       : High
```

```
Match_ipaddr : Exist
Mode          : redundance
Nexthop Count : 1
Nexthop[0]    : 1001::2
Weight[0]     : 1
Ifindex[0]    : 3
```

## 9.21 show ipv6 pbr statistics

Use this command to display the IPv6 PBR forwarded packet count.

**show ip pbr statistics** [ **interface** *if-name* | **local** ]

**Parameter  
Description**

| Parameter                       | Description                                                                                                                                                                                                                                        |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface</b> <i>if-name</i> | Specifies the interface name. If the interface name is specified, the IPv6 PBR forwarded packet count of this interface is displayed. Otherwise, the IPv6 PBR forwarded packet count of all interfaces where the IPv6 PBR is enabled is displayed. |
| <b>local</b>                    | Displays the IPv6 PBR forwarded packet count on the local interface.                                                                                                                                                                               |

**Defaults** N/A**Command  
Mode** Privileged EXEC mode**Usage Guide** N/A**Configuration** The following example displays the IPv6 PBR forwarded packet count.**Examples**

```
Ruijie#show ipv6 pbr statistics
IPv6 Policy-based route statistic
gigabitEthernet 0/1
  statistics : 20
```

**Description**

## 9.22 show ipv6 policy

Use this command to display which interfaces are configured with IPv6 PBR.

**show ipv6 policy** [ *route-map-name* ]

| Parameter<br>Description | Parameter             | Description                 |
|--------------------------|-----------------------|-----------------------------|
|                          | <i>route-map-name</i> | Name of the PBR router map. |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the current PBR applied in the system.

**Examples**

```
Ruijie#show ipv6 policy
Banlance Mode: redundance
Interface          Route map
VLAN 1             RM_for_Vlan_1
VLAN 2             RM_for_Vlan_2
```

| Field        | Description                                     |
|--------------|-------------------------------------------------|
| Balance Mode | The current PBR running mode.                   |
| Interface    | The name of interface with PBR applied.         |
| Route map    | The name of route map applied on the interface. |

| Related<br>Commands | Command               | Description                                |
|---------------------|-----------------------|--------------------------------------------|
|                     | <b>show route-map</b> | Displays the current configured route map. |

## 10 VRF Commands

### 10.1 address-family

Use this command to configure an IPv4 address family or IPv6 address family for a multiprotocol VRF.

**address-family** { **ipv4** | **ipv6** }

| Parameter<br>Description | Parameter   | Description                 |
|--------------------------|-------------|-----------------------------|
|                          | <b>ipv4</b> | Enters IPv4 address family. |
|                          | <b>ipv6</b> | Enters IPv6 address family. |
|                          |             |                             |

**Defaults** No IPv4 address family or IPv6 address family is configured for a multiprotocol VRF.

**Command mode** VRF configuration mode

**Usage Guide** This command is applicable only to the multiprotocol VRF.

**Configuration Examples** The following example defines a multiprotocol VRF vrf1 and configures an IPv4 address family.

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#
```

| Related<br>Commands | Command                    | Description                                      |
|---------------------|----------------------------|--------------------------------------------------|
|                     | <b>exit-address-family</b> | Exits the VRF address family configuration mode. |
|                     | <b>vrf definition</b>      | Defines a multiprotocol VRF.                     |
|                     |                            |                                                  |

**Platform** N/A

**Description**

### 10.2 description

Use this command to configure the VRF description.

**description** *string*

| <b>Parameter Description</b>  | Parameter                                                                                                                                                                                                                                                                                                                                                                                   | Description                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
|                               | <i>string</i>                                                                                                                                                                                                                                                                                                                                                                               | VRF description character string. The maximum length is 244 characters. |
| <b>Defaults</b>               | No VRF description is configured by default.                                                                                                                                                                                                                                                                                                                                                |                                                                         |
| <b>Command mode</b>           | VRF configuration mode                                                                                                                                                                                                                                                                                                                                                                      |                                                                         |

| <b>Description</b>            |                                                                                                                                                                                                                                                                                                                                                                                             |                                                                         |

## 10.3 exit-address-family

Use this command to exit VRF address family configuration mode.

**exit-address-family**

| <b>Parameter Description</b> | Parameter | Description |
|------------------------------|-----------|-------------|
|                              | N/A       | N/A         |
| <b>Defaults</b>              | N/A       |             |

**Command** VRF address family configuration mode  
**mode**

**Usage Guide** N/A

**Configuration** The following example defines a multiprotocol VRF *vrf1* and configures an IPv4 address family.

**Examples**

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)# exit-address-family
Ruijie(config-vrf)#
```

|-----------------------|-----------------------------------------------------------------------------------|
| <b>address-family</b> | Configures an IPv4 address family or IPv6 address family for a multiprotocol VRF. |
| <b>vrf definition</b> | Defines a multiprotocol VRF.                                                      |

**Platform** N/A

**Description**

## 10.4 ip vrf

Use this command to create a VRF. Use the **no** form of this command to delete a VRF.

**ip vrf** *vrf-name*

**no ip vrf** *vrf-name*

**Parameter  
Description**

| Parameter       | Description |
|-----------------|-------------|
| <i>vrf-name</i> | VRF name    |

**Defaults** No VRF is configured by default.

**Command** Global configuration mode  
**mode**

**Usage Guide** N/A

**Configuration** The following example creates a VRF.

**Examples**

```
Ruijie(config)# ip vrf redvrf
Ruijie(config-vrf)#
```

**Description**

## 10.5 ip vrf forwarding

Use this command to add an interface or sub-interface to a VRF. Use the **no** form of this command to quit the VRF.

**ip vrf forwarding** *vrf-name*

**no ip vrf forwarding** *vrf-name*

| Parameter<br>Description | Parameter       | Description                                               |
|--------------------------|-----------------|-----------------------------------------------------------|
|                          | <i>vrf-name</i> | Name of the VRF that the interface or sub-interface joins |

**Defaults** By default, the interface does not belong to any VRF.

**Command mode** Interface configuration mode

**Usage Guide** You can bind the interface to the uni-protocol IPv4 VRF without the IPv6 enabled on the interface. On the device supporting the VRF, if the interface is bound to the uni-protocol IPv4 VRF with the IPv6 protocol enabled, the device cannot forward the IPv6 packets received on this interface.

**Configuration** The following example adds an interface or sub-interface to a VRF.

**Examples** Ruijie(config-if-GigabitEthernet 0/0) # ip vrf forwarding redvrf

| Related<br>Commands | Command | Description |

**Description**

## 10.6 ip vrf receive

Use this command to import the host and direct-connected route of one interface into the specified VRF routing table. Use the **no** form of this command to remove the imported host and direct-connected route from the VRF.

**ip vrf receive** *vrf-name*

**no ip vrf receive** *vrf-name*

### Parameter Description

| Parameter       | Description                                                           |
|-----------------|-----------------------------------------------------------------------|
| <i>vrf-name</i> | Name of the VRF that the host and direct-connected route imported to. |

### Defaults

By default, the host and direct-connected route of the interface are not imported to other VRFs

### Command mode

Interface configuration mode

### Usage Guide

Currently, the **ip vrf receive** command supports the VRF routing based on the PBR. This command is used to import the host with the main and slave addresses and direct-connected route of this interface into the specified VRF routing table. You need to execute this command multiple times to import this host and direct-connected route to multiple VRF routing tables. Unlike the **ip vrf forwarding** command, which does not bind the interface to the VRF and this interface still belongs to the global VRF. Configuring both **ip vrf forwarding** and **ip vrf receive** on an interface is not allowed. If one has been configured, configuring the other one will prompt an error message.

If **ip vrf forwarding** has been configured, configuring **ip vrf receive** will prompt:

```
% Cannot configure 'ip vrf receive' if interface is under a VRF
```

If **ip vrf receive** has been configured, configuring **ip vrf forwarding** will prompt:

```
% Cannot bind interface to a VRF if it has configed 'ip vrf receive'
```

### Configuration Examples

The following example imports the host and direct-connected route of one interface into the specified VRF routing table.

```
Ruijie(config)# interface FastEthernet0/1
Ruijie(config-if)# ip address 192.168.1.2 255.255.255.0
Ruijie(config-if)# ip policy route-map PBR-VRF-SELECTION
Ruijie(config-if)# ip vrf receive VRF_1
Ruijie(config-if)# ip vrf receive VRF_2
Ruijie(config-if)# end
```

| Related<br>Commands | Command                  | Description                                         |
|---------------------|--------------------------|-----------------------------------------------------|
|                     | <b>ip vrf forwarding</b> | Adds the interface to a VRF.                        |
|                     | <b>ip vrf</b>            | Creates a VRF.                                      |
|                     | <b>set vrf</b>           | Sets the VRF in the routing map configuration mode. |

**Platform** N/A

**Description**

## 10.7 maximum routes

Use this command to set the maximum routes limit within the VRF. Use the **no** form of this command to remove the setting.

**maximum routes** *limit* { *warn-threshold* | **warning-only** }

**no maximum routes**

| Parameter<br>Description | Parameter             | Description                                                                                                                                         |
|--------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>limit</i>          | The maximum number of routes, in the range from 1 to 4,294,967,295. The routes which exceed the limits will not be added to the core routing table. |
|                          | <i>warn-threshold</i> | The warning will be printed when the threshold is reached. The threshold value is in the range from 1 to 100.                                       |
|                          | <b>warning-only</b>   | After the number of routes reaches <i>limit</i> , the warning will be printed but the routes will be added to the core routing table.               |

**Defaults** N/A

**Command Mode** Single-protocol VRF is configured in VRF configuration mode; multiple-protocol VRF is configured in address family mode.

**Usage Guide** This command is used to set the maximum number of routes for the VRF.

**Configuration Examples** The following example sets the maximum number of routes for vrf1 to 1,000, and enables the device to only print the warning.

```
Ruijie(config)# ip vrf vrf1
Ruijie(config-vrf)# maximum routes 1000 warning-only
```

## 10.8 vrf definition

Use this command to create the multiprotocol VRF.

**vrf definition** *vrf-name*

**Parameter  
Description**

| Parameter       | Description                           |
|-----------------|---------------------------------------|
| <i>vrf-name</i> | VRF name, no more than 31 characters. |

**Defaults** N/A**Command  
mode** Global configuration mode

**Usage Guide** The single-protocol VRF configuration command **ip vrf** cannot be used to edit a multiprotocol VRF; the multiprotocol VRF configuration command **vrf definition** cannot be used to edit a single-protocol IPv4 VRF.

**Configuration** The following example s creates a multiprotocol VRF *vrf1*.

**Examples**

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#
```

**Related  
Commands**

| Command                    | Description                                                                       |
|----------------------------|-----------------------------------------------------------------------------------|
| <b>description</b>         | Configures the description.                                                       |
| <b>address-family</b>      | Configures an IPv4 address family or IPv6 address family for a multiprotocol VRF. |
| <b>exit-address-family</b> | Exits the VRF address family configuration mode.                                  |
| <b>vrf forwarding</b>      | Binds a network interface to a multiprotocol VRF.                                 |

**Platform** N/A

**Description**

## 10.9 vrf forwarding

Use this command to bind a network interface to a multiprotocol VRF.

**vrf forwarding** *vrf-name*

**Parameter  
Description**

| Parameter       | Description                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | VRF name, which shall be a multiprotocol VRF instead of a single-protocol VRF that supports IPv4 only. |

**Defaults**

The network interface is not bound to any VRF.

**Command  
mode**

Interface configuration mode

**Usage Guide**

The configuration command **ip vrf forwarding** cannot be used to bind a network interface to a multiprotocol VRF; the configuration command **vrf forwarding** cannot be used to bind a network interface to a single-protocol IPv4 VRF.

An interface cannot be bound to a multiprotocol VRF that is not configured with any address family. To bind a network interface to a multiprotocol VRF, you should delete the existing IPv4 addresses, VRRP IPv4 addresses, IPv6 addresses and VRRP IPv6 addresses, and disable IPv6 on the interface. When a network interface is bound to a multiprotocol VRF, no IPv4 address or VRRP IPv4 address should be configured for the interface if no IPv4 address family is configured for the VRF. You should configure an IPv4 address family for the VRF before configuring an IPv4 address and VRRP IPv4 address for the interface.

When a network interface is bound to a multiprotocol VRF, no IPv6 address or VRRP IPv6 address should be configured for the interface if no IPv6 address family is configured for the VRF. You should configure an IPv6 address family for the VRF before configuring an IPv6 address and VRRP IPv6 address for the interface.

If you delete a multiprotocol VRF's IPv4 address family, you should delete the IPv4 addresses and VRRP IPv4 addresses of all network interfaces bound to the VRF, and delete the IPv4 static routes whose routing VRF or next-hop VRF is that VRF. Likewise, if you delete a multiprotocol VRF's IPv6 address family, you should delete the IPv4 addresses and VRRP IPv6 addresses of all network interfaces bound to the VRF, disable IPv6 on the interfaces, and delete the IPv6 static routes whose routing VRF or next-hop VRF is that VRF.

**Configuration**

The following example binds the interface VLAN 1 to a multiprotocol VRF vrf1.

**Examples**

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#address-family ipv4
```

```
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family

Ruijie(config-vrf)#interface vlan 1
Ruijie(config-if)#vrf forwarding vrf1
Ruijie(config-if)#ip address 1.1.1.1 255.255.255.0
Ruijie(config-if)#ipv6 address 1000::1/64
```

Commands**

| Command | Description |
|---------|-------------|
|---------|-------------|

**Platform** N/A**Description**

## 10.11 vrf receive

Use this command to add the local host's route and direct route with the interface's IPv4/v6 address to the routing table of the specified VRF.

**vrf receive** *vrf-name*

| Parameter Description | Parameter       | Description                                                                          |
|-----------------------|-----------------|--------------------------------------------------------------------------------------|
|                       | <i>vrf-name</i> | VRF name, which should be a multiprotocol VRF instead of a single-protocol IPv4 VRF. |

**Defaults** N/A

**Command mode** Interface configuration mode

**Usage Guide** This command is not used to bind an interface to a VRF, and the interface is still a global interface. If the administrator needs to use PBR to choose VRF, the **vrf receive** command should be configured on the interfaces where PBR is applied for each selected VRF.

When an IPv4 address family is configured for a multiprotocol VRF, the local host's route and direct route with the interface's IPv4 address is added to the IPv4 routing table of the specified VRF, and the local host's route with the IPv4 address of the master VRRP group on the interface is added to the IPv4 routing table of the specified VRF. When an IPv6 address family is configured for a multiprotocol VRF, the local host's route and direct route with the interface's IPv6 address is added to the IPv6 routing table of the specified VRF, and the local host's route with the IPv6 address of the master VRRP group on the interface is added to the IPv6 routing table of the specified VRF.

The **ip vrf forwarding** and **vrf receive** commands are mutually exclusive on an interface, and so are the **vrf forwarding** and **vrf receive** commands. If both commands are configured on an interface, an error message will be shown.

If the **ip vrf forwarding** or **vrf forwarding** command is configured first, and then the **vrf receive** command is configured, the following message will be displayed:

```
% Cannot configure 'vrf receive' if interface is under a VRF
```

If the **vrf receive** command is configured first, and then the **ip vrf forwarding** or **vrf forwarding** command is configured, the following message will be displayed:

```
% Cannot configure 'vrf forwarding vrf2' on this interface, please delete 'ip vrf receive' and 'vrf receive' first.
```

**Configuration** The following example selects a VRF using IPv6 PBR on VLAN 1.

**Examples**

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family
```

```

Ruijie(config-vrf)#vrf definition vrf2
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family

Ruijie(config-vrf)#route-map pbr-vrf-selection permit 10
Ruijie(config-route-map)#match ipv6 address acl1
Ruijie(config-route-map)#set vrf vrf1
Ruijie(config-route-map)#route-map pbr-vrf-selection permit 20
Ruijie(config-route-map)#set vrf vrf2

Ruijie(config-route-map)#interface vlan 1
Ruijie(config-if)#ipv6 policy route-map pbr-vrf-selection
Ruijie(config-if)#ipv6 address 1000::1/64
Ruijie(config-if)#vrf receive vrf1
Ruijie(config-if)#vrf receive vrf2

```

#### Description

## 10.12 show ip vrf

Use this command to display the VRF information.

**show ip vrf [ **brief** | **detail** | **interfaces** ] [ *vrf-name* ]**

#### Parameter Description

| Parameter         | Description                                                    |
|-------------------|----------------------------------------------------------------|
| <b>brief</b>      | (Optional) Displays the VRF information in brief.              |
| <b>detail</b>     | (Optional) Displays the VRF information in detail.             |
| <b>interfaces</b> | (Optional) Displays the VRF's interface information in detail. |
| <i>vrf-name</i>   | (Optional) Name of the VRF                                     |

**Defaults** N/A

**Command mode** Privileged EXEC mode

**Usage Guide** Use this command to display the VRF information, which can be divided into two levels:  
Use the keyword **brief** to display the information in brief.  
Use the keyword **detail** to display the information in detail.  
Use the keyword **interfaces** to display the VRF's interface information.

**Configuration** The following example displays the VRF information.

**Examples**

```
Ruijie#show ip vrf
Name                               Interfaces
aaa                               GigabitEthernet 0/0
                                   GigabitEthernet 0/1
```

## 10.14 show global-vrf

Use this command to display the VRF configuration (including the single-protocol VRF and the multiple-protocol VRF).

**show global-vrf** [ **ipv4** | **ipv6** | **brief** | **count** | **detail** ] [ *vrf-name* ]

**Parameter  
Description**

| Parameter     | Description                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>   | Displays the brief VRF (the single-protocol VRF) information of the IPv4 address family.             |
| <b>ipv6</b>   | Displays the VRF brief information of the IPv6 address family.                                       |
| <b>brief</b>  | Displays the brief VRF (including the single-protocol VRF and the multiple-protocol) information.    |
| <b>detail</b> | Displays the detailed VRF (including the single-protocol VRF and the multiple-protocol) information. |

**Defaults** N/A**Command mode** Privileged EXEC mode**Usage Guide** N/A**Configuration** The following example displays brief information about all VRF.**Examples**

Ruijie#show global-vrf

| Name         | Default RD | Protocol(s) | Interface |
|--------------|------------|-------------|-----------|
| @#global-vrf | <not set>  | ipv4,ipv6   | VLAN 1:   |

| Field      | Description                                                                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name       | Global VRF name.                                                                                                                                                            |
| Default RD | Default RD of the global VRF.                                                                                                                                               |
| Protocol   | The address family of the global VRF. IPv4 indicates the VRF is enabled in the IPv4 address family mode; ipv6 indicates the VRF is enabled in the IPv6 address family mode. |
| Interfaces | The interface list of the global VRF. The interface where the [ip] vrf forwarding command has been configured will be displayed on that list.                               |

## 11 L3MAC Commands

### 11.1 l3intf-mac-add

Use this command to add a layer-3 MAC address. Use the **no** form of this command to delete the configured layer-3 MAC address of the device.

**l3intf-mac-add** *mac-id*

**no l3intf-mac-add** *mac-id*

| Parameter<br>Description | Parameter     | Description                        |
|--------------------------|---------------|------------------------------------|
|                          | <i>mac-id</i> | Indicates the layer-3 MAC address. |

**Defaults** N/A

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** If the destination MAC address of a packet matches the configured layer-3 MAC address, layer-3 routing can be triggered for this packet.

**Configuration Example** The following example adds the layer-3 MAC address 000.1122.3355 to the device.

```
Ruijie#configure terminal
Ruijie(config)#l3intf-mac-add 0000.1122.3355
```

**Verification**

1. Run the **show run** command to check whether the current configuration is correct.
2. Run the **show l3intf-mac-add** command to check whether the current configuration is correct.

**Prompt** N/A

**Common Errors** N/A

**Platform Description** N/A

## 11.2 show l3intf-mac-add

Use this command to display the configured layer-3 MAC address of the device.

**show l3intf-mac-add**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Example** The following example displays the configured layer-3 MAC address.

```
Ruijie(config)#show l3intf-mac-add  
  
l3intf mac address:  
  
0000.0001.2235
```

**Prompt** N/A

**Platform Description** N/A

## 12 Hardware Capacity Query Commands

### 12.1 show route-res usage slot *slot\_num*

Use this command to display the FIB hardware capacity and resource usage of a specified line card in standalone mode.

**show route-res usage slot** *slot\_num*

| Parameter Description | Parameter       | Description                                                                                                                         |
|-----------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>slot_num</i> | Specifies the ID of the slot in which the line card of the chassis-type device resides, where <b>0</b> indicates a box-type device. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode, global configuration mode, and interface configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Example** The following example displays the FIB hardware capacity and resource usage on the S6220H, S6500 or N18000-X DB series products.

```
Ruijie#show route-res usage slot 0

## 12.2 show route-res usage switch *switch\_num* slot *slot\_num*

Use this command to display the FIB hardware capacity and resource usage of a specified line card in VSU mode.

**show route-res usage switch** *switch\_num* **slot** *slot\_num*

| Parameter Description | Parameter         | Description                                                                                                                             |
|-----------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>switch_num</i> | Indicates the device ID of the chassis- or box-type device in VSU mode. In standalone mode, the keyword <b>switch</b> is not displayed. |
|                       | <i>slot_num</i>   | Specifies the ID of the slot in which the line card of the chassis-type device resides, where <b>0</b> indicates a box-type device.     |

**Defaults** N/A

**Command Mode** Privileged EXEC mode, global configuration mode, and interface configuration mode

**Default Level** 14

**Usage Guide**      N/A

**Configuration Example**      The following example displays the FIB hardware capacity and resource usage on the S6220H, S6500 or N18000-X DB series products.

```
Ruijie#show route-res usage switch 1 slot 0
```

```
Switch Mode Current:default
```

```
Switch Mode Next :default
```

```
-----
```

# 1 IPv4 Multicast Routing Commands

## 1.1 clear ip mroute

Use this command to remove the forwarding information of the IP multicast routes.

**clear ip mroute** { \* | *group-address* [*source -address*] }

| Parameter Description | Parameter             | Description                                                             |
|-----------------------|-----------------------|-------------------------------------------------------------------------|
|                       | *                     | Removes all the forwarding information in the IP multicast route table. |
|                       | <i>group-address</i>  | Group IP address of IP multicast routes                                 |
|                       | <i>source-address</i> | Source IP address of multicast routes                                   |

**Command Mode** Privileged EXEC mode

**Configuration Examples** The following example removes the entry whose group IP address is 230.0.0.1 from the multicast routing table:

```
Ruijie# clear ip mroute 230.0.0.1
```

| Related Commands | Command               | Description                                              |
|------------------|-----------------------|----------------------------------------------------------|
|                  | <b>show ip mroute</b> | Displays the forwarding information of multicast routes. |

**Platform**

**Description** N/A

## 1.2 clear ip mroute statistics

Use this command to remove the statistics of IP multicast routes.

**clear ip mroute statistics** { \* | *group-address* [*source -address*] }

| Parameter Description | Parameter             | Description                                                      |
|-----------------------|-----------------------|------------------------------------------------------------------|
|                       | *                     | Removes all the forwarding entries in the multicast route table. |
|                       | <i>group-address</i>  | Group IP address of IP multicast routes                          |
|                       | <i>source-address</i> | Source IP address of multicast route                             |

**Command Mode** Privileged EXEC mode

**Usage Guide** This command allows you to clear the statistics information of IP multicast routes.

**Configuration**

The following example clears the statistics of entry with the group IP address 230.0.0.1 from the multicast routing table.

**Examples**

```
Ruijie# clear ip mroute statistics 230.0.0.1
```

**Related Commands**

| Command                | Description                                          |
|------------------------|------------------------------------------------------|
| <b>show ip mroute</b>  | Displays the multicast route forwarding information. |
| <b>clear ip mroute</b> | Clears the multicast route forwarding information.   |

**Platform****Description**

N/A

## 1.3 ip mroute

Use this command to configure static multicast routes.

Use the **no** form of this command to delete the configured routes.

Use the **default** form of this command to restore the default setting.

**ip mroute** *source-address mask* { [ *protocol* ] { *rpf-address* | *interface-type interface-number* } } [ *distance* ]

**no ip mroute** *source-address mask* [*protocol as-number*] { *rpf-address* | *interface-type interface-number* } [*distance*]

**default ip mroute** *source-address mask* [ *protocol* ]

**Parameter****Description**

| Parameter                                        | Description                                                                                            |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <i>source-address</i>                            | Source IP address of the multicast route                                                               |
| <i>mask</i>                                      | Mask of the source IP address                                                                          |
| <i>protocol</i>                                  | (Optional) The unicast routing protocol being used                                                     |
| <i>rpf-address</i>                               | Incoming interface of the multicast route                                                              |
| <i>interface-type</i><br><i>interface-number</i> | Interface type and interface ID                                                                        |
| <i>distance</i>                                  | Management distance used to determine whether to use the route for RPF routing, ranging from 1 to 255. |

**Defaults**

The default is 0.

**Command Mode**

Global configuration mode

**Usage Guide**

This command is used to configure the route for the purpose of RFF check. Note that the configured route is prior to the route learned in the unicast form.

**Configuration**

The following example allows the multicast routes of all the sources in a network to pass 172.30.10.13.

**Examples**

```
Ruijie(config)# ip mroute 172.16.0.0 255.255.0.0
172.30.10.13
```

**Platform****Description** N/A

## 1.4 ip multicast-routing

Use this command to enable multicast routing forwarding.

Use the **no** form of this command to disable multicast routing forwarding.

Use the **default** form of this command to restore the default setting.

**ip multicast-routing**

**no ip multicast-routing**

**default ip multicast-routing**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command allows you to enable IPv4 multicast routing forwarding. The multicast protocol will not be enabled with IPv4 multicast routing forwarding disabled.

**Configuration Examples** This command enables multicast routing forwarding.

```
Ruijie(config)# ip multicast-routing
```

**Platform Description** N/A

## 1.5 ip multicast boundary

Use this command to configure the boundary of an IP multicast group.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default setting.

**ip multicast boundary** *access-list*

**no ip multicast boundary** *access-list*

**default ip multicast boundary** *access-list* [ **in** | **out** ]

| Parameter   | Parameter          | Description                                        |
|-------------|--------------------|----------------------------------------------------|
| Description | <i>access-list</i> | Access list associated with the multicast boundary |

**Defaults** The boundary of a specified IP multicast group is defined by default.

**Command Mode** Interface configuration mode

Note that the ACL associated with the multicast boundary is either standard ACL or extended ACL. But the extended ACL only match the destination IP address.

**Usage Guide**

Note:

This command filters IGMP and PIMSM packets of the specified IP address range. Multicast packets will not be received and sent through the interface of the boundary.

**Configuration Examples**

The following example configures svi1 as the boundary of all IP multicast groups.

```
Ruijie(config)# ip access-list mul-boun
Ruijie(config-std-nacl)# permit ip 233.3.3.0 0.0.0.255
Ruijie(config-std-nacl)#exit
Ruijie(config)# interface vlan 1
Ruijie(config-if)# ip multicast boundary mul-boun
```

## 1.6 ip multicast route-limit

Use this command to limit the number of the entries that can be added to the multicast routing table.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default setting.

**ip multicast route-limit** *limit* [*threshold*]

**no ip multicast route-limit**

**default ip multicast route-limit**

**Parameter**

**Description**

| Parameter        | Description                                                                                    |
|------------------|------------------------------------------------------------------------------------------------|
| <i>limit</i>     | The number of the entries that can be added to the multicast routing table is 1 to 2147483647. |
| <i>threshold</i> | (Optional) Number of multicast routes at which alarms will be triggered.                       |

**Defaults**

The default value of *limit* is 1024.

The default value of *threshold* is 2147483647.

**Command Mode**

Global configuration mode

**Usage Guide**

This command is used to restrict the number of route adding to the IPv6 multicast table. Note that the hardware resources of different devices are limited. The routes exceeding the hardware resource will be forwarded by software, which leads to lower product performance.

If you want to use the PIM protocol to create more than 128 entries in the multicast routing table, you are advised to set the CPP value of PIM packets to the number of entries in the multicast routing table. If you want to use the IGMP protocol to create more than 1000 entries in the multicast routing table, you are advised to set the CPP value of IGMP packets to the number of entries in the multicast routing table.

**Configuration** The following example sets the route limit to 500.

**Examples** Ruijie(config)# ip multicast route-limit 500

**Platform**

**Description** N/A

## 1.7 ip multicast rpf longest-match

Select the multicast static routing, MBGP routing and unicast routing that could be used for the RPF check from the multicast static routing table, MBGP routing table and unicast routing table respectively by following the RPF rules.

Use this command to select the one with the mask longest-matched from the three routings. If the routings are in the same priority, select the routing in order of multicast static routing, MBGP routing, unicast routing.

Use the **no** or **default** form of this command to restore it to the default setting. By default, select one routing of the highest priority from the three routings. If the routings are in the same priority, select the routing in order of multicast static routing, MBGP routing, unicast routing.

**ip multicast rpf longest-match**

**no ip multicast rpf longest-match**

**default ip multicast rpf longest-match**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** Select the multicast static routing, MBGP routing and unicast routing that are used for the RPF check from the multicast static routing table, MBGP routing table and unicast routing table respectively by following the RPF rules. Then select one routing of the highest priority from the three routings. If the routings are in the same priority, select the routing in order of multicast static routing, MBGP routing, unicast routing.

**Command Mode** Global configuration mode

**Configuration** The following example configures to select the routing with the longest-match.

**Examples** Ruijie(config)# ip multicast rpf longest-match

**Platform**

**Description** N/A

## 1.8 ip multicast static

Use this command to enable flow control for multicast packets on the Layer 2 interface.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default setting.**ip multicast static** *source-address group-address interface-type interface-number*

**no ip multicast static** *source-address group-address interface-type interface-number*

**default ip multicast static** *source-address group-address interface-type interface-number*

### Parameter Description

| Parameter                              | Description                                                         |
|----------------------------------------|---------------------------------------------------------------------|
| <i>source-address</i>                  | Source IP address                                                   |
| <i>group-address</i>                   | IP address of the multicast group                                   |
| <i>interface-type interface number</i> | Layer 2 interface on which multicast packets are allowed to forward |

### Defaults

This function is disabled by default

### Command Mode

Global configuration mode

### Usage Guide

You can configure more than one command (or more than one interface) for a multicast flow. With flow control enabled, the multicast flow can only be forwarded through these configured interfaces.

This command controls the forwarding of multicast flows on an interface without any direct influence on the packet processing of multicast protocols. However, the action of a multicast protocol (for instance, PIM-DM or PIM-SM) may be affected because some features of the multicast protocol are driven by multicast flows.

### Configuration

The following example configures forwarding multicast flows (192.168.43.4 and 255.1.1.5) through GigabitEthernet 2/6 and FastEthernet 3/2.

### Examples

```
Ruijie(config)# ip multicast static 192.168.43.4 225.1.1.5 G2/6
Ruijie(config)# ip multicast static 192.168.43.4 225.1.1.5 F3/2
```

### Platform

#### Description

N/A

## 1.9 ip multicast ttl-threshold

Use this command to configure TTL (time-to-live) threshold on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip multicast ttl-threshold** *ttl-value*

**no ip multicast ttl-threshold**

**default ip multicast ttl-threshold**

| Parameter   | Parameter        | Description                                                   |
|-------------|------------------|---------------------------------------------------------------|
| Description | <i>ttl-value</i> | TTL threshold on the interface, within the range of 0 to 255. |

**Defaults** The default *ttl-value* is 0.

**Command Mode** Interface configuration mode

**Usage Guide** Use **show running-config** to display configuration. A device with multicast enabled can maintain one TTL threshold for every interface. If the TTL of the multicast packet received is greater than the threshold of the interface, the packets will be forwarded. Otherwise, the packet is discarded. Note that the TTL threshold is effective only to the multicast frames. In addition, you must configure it on the L3 interface.

**Configuration** The following example sets the TTL threshold on the interface to 5.

**Examples**  
Ruijie(config-if)# ip multicast ttl-threshold 5

## 1.10 msf ipmc-overflow override

Use this command to enable the overflow overriding mechanism.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default setting.

**msf ipmc-overflow override**

**no msf ipmc-overflow override**

**default msf ipmc-overflow override**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration** The following example enables the overflow overriding mechanism.

**Examples**  
Ruijie (config)# msf ipmc-overflow override  
Ruijie (config)#

**Platform****Description** N/A

## 1.11 msf nsf

Use this command to configure the parameter for the continuous multicast forwarding.

Use the **no** or **default** form of this command to restore the default setting.

**msf nsf** { **convergence-time** *time* | **leak** *interval* }

**no msf nsf** {**convergence-time** | **leak**}

**default msf nsf** {**convergence-time** | **leak**}

**Parameter****Description**

| Parameter                           | Description                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------|
| <b>convergence-time</b> <i>time</i> | Maximum time for the multicast protocol convergence, in the valid range of the 0-3600s. |
| <b>leak</b> <i>interval</i>         | Packet multicast leak time, in the valid range of 0-3600s                               |

**Defaults****convergence-time** *time* :20s**leak** interval: 30s**Command Mode**

Global configuration mode

**Usage Guide**

N/A

**Configuration****Examples**

The following example sets the maximum time for the protocol convergence.

```
Ruijie (config)# msf nsf convergence-time 300
Ruijie (config)#
```

The following example sets the packets leak time:

```
Ruijie(config)# msf nsf leak 200
Ruijie(config)#
```

**Platform****Description** N/A

## 1.12 show ip mrf mfc

Use this command to display the IPv4 multicast routing forwarding table.

**show ip mrf mfc** [*source-address group-address*]

| Parameter<br>Description | Parameter             | Description                                                |
|--------------------------|-----------------------|------------------------------------------------------------|
|                          | <i>source-address</i> | Source address of the multicast routing forwarding entries |
|                          | <i>group-address</i>  | Group address of the multicast routing forwarding entries  |

**Defaults** All IPv4 multicast routing forwarding entries are displayed by default.

**Command Mode** Global configuration mode/Interface configuration mode/Privileged EXEC mode

The three parameters in this command are optional, wherein the source address and group address must be specified at the same time.

- Usage Guide**
- If no source address and group address are specified, all mfc entries are displayed.
  - When the source address and group address are specified only, the entries corresponding to the source and group addresses are displayed.

The following example shows all IPv4 layer-3 multicast routing forwarding entries with source address 20.0.1.30.

```
Ruijie#show ip mrf mfc 20.0.1.30 233.3.3.3
Multicast Routing and Forwarding Cache Table
(20.0.1.30, 233.3.3.3)
FAST_SW, SWITCHED, MIN_MTU: 1500, MIN_MTU_IFINDEX: 4099, WRONG_IF: 0
Incoming interface: VLAN 1[4097]
Outgoing interface list:
VLAN 3 (1)
```

## Configuration Examples

The fields in the execution of the **show ip mrf mfc** command are described in the following table.

| Field              | Description                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20.0.1.30          | Source address of the entry.                                                                                                                                    |
| 233.3.3.3          | Group address of the entry.                                                                                                                                     |
| FAST_SW            | The Flag shows whether to allow the fast forwarding or not. If the non-Ethernet interface, ppp, hdlc and frame relay exist, no fast forwarding entry generates. |
| SWTCHED            | Indicate whether the entry configuration on the next layer forwarding table has done not not.                                                                   |
| MIN_MTU MTU        | The minimum MTU of the entry.                                                                                                                                   |
| MIN_MTU_IFINDEX    | The interface index with the minimum MTU value.                                                                                                                 |
| WRONG IF           | The statistics number of the multicast data packets received on the wrong incoming interface.                                                                   |
| Incoming interface | Incoming interface of the entry.                                                                                                                                |
| VLAN 3 (1)         | The layer-3 outgoing interface of the entry is VLAN3. 1 for the ttl threshold of this layer-3 interface.                                                        |

**Platform**

**Description** N/A

## 1.13 show ip mroute

Use this command to display the multicast forwarding table.

**show ip mroute** [*group-or-source-address* [*group-or-source-address*]] [**dense** | **sparse**] [**summary** | **count**]

**Parameter Description**

| Parameter                      | Description                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>group-address</i>           | Multicast group IP address                                                                                                  |
| <i>group-or-source-address</i> | Multicast or source IP address                                                                                              |
| <i>group-or-source-address</i> | Multicast or source IP address. The two addresses must not be the multicast addresses or source addresses at the same time. |
| <b>dense</b>                   | Displays PIM-DM multicast routing table.                                                                                    |
| <b>sparse</b>                  | Displays PIM-SM multicast routing table.                                                                                    |
| <b>summary</b>                 | Displays the summary of the multicast routing table.                                                                        |
| <b>count</b>                   | Displays the count of the multicast routing table.                                                                          |

**Command Mode** Global configuration mode/Interface configuration mode/Privileged EXEC mode

**Configuration** The following example displays the information of the multicast routing table:

**Examples**

```
Ruijie# show ip mroute
IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(10.10.1.52, 224.0.1.3), uptime 00:00:31, stat expires 00:02:59
Owner PIM-SM, Flags: TF
Incoming interface: FastEthernet 2/1
Outgoing interface list:
FastEthernet 1/3
```

The following example displays the information of a specific entry:

```
Ruijie# show ip mroute 10.10.1.52 224.0.1.3
IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(10.10.1.52, 224.0.1.3), uptime 00:03:24, stat expires 00:01:28
Owner PIM-SM, Flags: TF
Incoming interface: FastEthernet 2/1
Outgoing interface list:
FastEthernet 1/3
```

The following example displays the count of the routing table:

```
Ruijie# show ip mroute count
IP Multicast Statistics
Total 1 routes using 132 bytes memory
Route limit/Route threshold: 2147483647/2147483647
Total NOCACHE/WRONGVIF/WHOLEPKT recv from fwd: 1/0/0
Total NOCACHE/WRONGVIF/WHOLEPKT sent to clients: 1/0/0
Immediate/Timed stat updates sent to clients: 0/0
Reg ACK recv/Reg NACK recv/Reg pkt sent: 0/0/0
Next stats poll: 00:01:10
Forwarding Counts: Pkt count/Byte count, Other Counts: Wrong If pkts
Fwd msg counts: WRONGVIF/WHOLEPKT recv
Client msg counts: WRONGVIF/WHOLEPKT/Imm Stat/Timed Stat sent
Reg pkt counts: Reg ACK recv/Reg NACK recv/Reg pkt sent
(10.10.1.52, 224.0.1.3), Forwarding: 2/19456, Other: 0
Fwd msg: 0/0, Client msg: 0/0/0/0, Reg: 0/0/0
```

The following example displays the summary of the routing table:

```
Ruijie# show ip mroute summary
IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
```

```
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(10.10.1.52, 224.0.1.3), 00:01:32/00:03:20, PIM-SM, Flags: T
```

| Field                                    | Description                                                                                                            |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Flags                                    | I-Immediate statistic<br>T-Timed statistic<br>F-Already set to the forwarding table                                    |
| Timers:Uptime/Stat Expiry                | Time when the entry is created.<br>Time when it is aged.                                                               |
| Interface State                          | Interface state.                                                                                                       |
| Owner                                    | Owner of the entry, which may be a multicast routing protocol                                                          |
| Incoming interface                       | Expected packet incoming interface. If the actual incoming interface does not match it, the packets will be discarded. |
| Outgoing interface list                  | Outgoing interface list; the packets will be forwarded on the interfaces in the list.                                  |
| Forwarding Counts: Pkt count/Byte count, | Forwarding count: packet count/byte count forwarded by the entry                                                       |
| Other Counts: Wrong If pkts              | Count of the packets received from the wrong incoming interface.                                                       |

## Related Commands

| Command                     | Description                               |
|-----------------------------|-------------------------------------------|
| <b>ip multicast-routing</b> | Enables the multicast routing forwarding. |
| <b>ip pim dense-mode</b>    | Enables the PIM-DM on the interface.      |
| <b>ip pim sparse-mode</b>   | Enables the PIM-SM on the interface.      |

## Platform Description

N/A

## 1.14 show ip mroute static

Use this command to display the IPv4 static multicast routing information.

**show ip mroute static**

## Parameter

## Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

## Command Mode

Global configuration mode/Interface configuration mode/Privileged EXEC mode

**Usage Guide** Use this command to show the user-configured static multicast routing. In the same conditions, the priority of the static multicast routing is higher than the dynamically learned.

The following example displays the information of the user-configured static multicast routing:

**Configuration**

```
Ruijie#show ip mroute static
```

**Examples**

```
Mroute: 172.16.0.0, RPF neighbor: 172.30.10.13
Protocol: , distance: 0
```

**Platform Description** N/A

## 1.15 show ip mvif

Use this command to show the basic information of the multicast interface.

**show ip mvif** { *interface-type interface-number* }

**Parameter****Parameter****Description****Description**

*interface-type interface-number*

Interface Type and number

**Command Mode** Global configuration mode/Interface configuration mode/Privileged EXEC mode

The following example shows the basic information of the multicast interface of svil.

**Configuration**

```
Ruijie#show ip mvif vlan 1
```

**Examples**

```
Interface Vif Owner TTL Local Remote Uptime
Idx Module Address Address
VLAN 1 1 PIM-DM 2 192.168.1.1 0.0.0.0 00:13:16
```

**Platform****Description**

N/A

## 1.16 show ip rpf

Use this command to display the RPF information of the specified source IP address.

**show ip rpf** {*source-address* [*group-address*] [*rd route-distinguisher*]} [*metric*]

**Parameter****Parameter****Description****Description**

*source-address*

Specified source IP address

|                                        |                                            |
|----------------------------------------|--------------------------------------------|
| <i>group-address</i>                   | Specified source IP address                |
| <b>rd</b> <i>route-disting unisher</i> | Uses the RD provy for the searching.       |
| <b>metric</b>                          | Displays the metric of the MDT-SAFI route. |

**Command Mode** Global configuration mode/Interface configuration mode/Privileged EXEC mode

The following example displays the information of the RPF to 192.168.1.54:

### Configuration Examples

```
Ruijie# show ip rpf 192.168.1.54
RPF information for 192.168.1.54
RPF interface: VLAN 1
RPF neighbor: 0.0.0.0
RPF route: 192.168.1.0/24
RPF type: unicast (connected)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 0
Metric: 0 RPF information for 192.168.1.54
RPF interface: VLAN 1
RPF neighbor: 0.0.0.0
RPF route: 192.168.1.0/24
RPF type: unicast (connected)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 0
Metric: 0
```

**Platform**

**Description** N/A

## 1.17 show msf msc

Use this command to display IPv4 multi-layer multicast forwarding table.

**show msf msc** [*source-address*] [*group-address*] [*vlan-id*]

### Parameter Description

| Parameter             | Description                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>source-address</i> | Specified source IP address of the multi-layer multicast forwarding table.                                               |
| <i>group-address</i>  | Specified group address of the multi-layer multicast forwarding table.                                                   |
| <i>vlan-id</i>        | The VLAN ID where the incoming interface of the multi-layer multicast forwarding table is. 4096 indicates a routed port. |

**Defaults** All IPv4 multi-layer multicast forwarding entries are displayed by default.

**Command****Mode**

Global configuration mode/Interface configuration mode/Privileged EXEC mode

The three parameters in this command are optional.

If no source address and group address are specified, all mfc entries are displayed.

**Usage Guide**

- If only the source address is specified as s1, all msc entries with source address 1 are displayed.
- If the source address is specified as s1 and the group address as g1, all corresponding msc entries are displayed.
- If the source address is specified as s1, the group address as g1 and the vlan id as v1, all corresponding msc entries are displayed.
- Each parameter shall be input in order. Only when the parameter in front has been configured, the following one could be set.

The following example displays the IPv4 layer-3 multicast forwarding entries with source IP address 192.168.195.25:

**Configuration Examples**

```
Ruijie# show msf msc 192.168.195.25
Multicast Switching Cache Table
(192.168.195.23, 233.3.3.3, 1), SYNC, MTU:0, 1 OIFs
VLAN 1(0): 1 OPORTs, REQ: DONE
OPORT 6, IGMP-SNP, REQ: DONE
```

The fields in the execution of the **show mrf mfc** command are described in the following table.

| Field          | Description                                                                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 192.168.195.23 | Source address of the entry.                                                                                                                                                                                              |
| 233.3.3.3      | Group address of the entry.                                                                                                                                                                                               |
| 1              | Vlan id where the incoming interface of the entry is.                                                                                                                                                                     |
| SYNC           | The entry has been synchronized to the hardware.                                                                                                                                                                          |
| MTU            | MTU value                                                                                                                                                                                                                 |
| OIFs           | Layer-3 outgoing interface number.                                                                                                                                                                                        |
| VLAN1(0)       | The vlan where the layer-3 outgoing interface oif is.                                                                                                                                                                     |
| 1 OPORTs       | The number of layer-2 port in the layer-3 outgoing oif.                                                                                                                                                                   |
| REQ: DONE      | This oif configuration on the hardware has done.                                                                                                                                                                          |
| OPORT 6        | The layer-2 port in the oif with index 6.                                                                                                                                                                                 |
| IGMP-SNP       | This port is created by the IGMP SNOOPING protocol. This value can also be the PIM-SNP, which means this port is created by the PIM SNOOPING protocol. And the ROUTER means this port is created by the layer-3 protocol. |
| REQ: DONE      | The port configuration on the hardware has done.                                                                                                                                                                          |

**Platform****Description** N/A

## 1.18 show msf nsf

Use this command to display the configuration of continuous multicast forwarding.

**show msf nsf****Parameter****Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Command Mode**

Global configuration mode/Interface configuration mode/Privileged EXEC mode

**Configuration****Examples**

The following example displays the configuration of continuous multicast forwarding.

```
Ruijie# show msf nsf
Multicast HA Parameters
-----+-----+
protocol convergence timeout 120 secs
flow leak interval 20 secs
Ruijie#
```

## 2 IPv6 Multicast Routing Commands

### 2.1 clear ipv6 mroute

Use this command to remove the specific or all IPv6 multicast forwarding entries.

**clear ipv6 mroute** { \* | *v6group-address* [*v6source -address*]

| Parameter Description | Parameter               | Description                                                               |
|-----------------------|-------------------------|---------------------------------------------------------------------------|
|                       | *                       | Removes all the forwarding information in the IPv6 multicast route table. |
|                       | <i>v6group-address</i>  | Group IPv6 address of IPv6 multicast routes.                              |
|                       | <i>v6source-address</i> | Source IPv6 address of multicast routess.                                 |

**Command Mode** Privileged EXEC mode

**Configuration** The following example removes all the multicast routing entries.

**Examples** Ruijie# clear ip mroute \*

| Related Commands | Command                      | Description |
|------------------|------------------------------|-------------|
|                  | show ipv6 mroute             | N/A         |
|                  | clear ipv6 mroute statistics | N/A         |

### 2.2 clear ipv6 mroute statistics

Use this command to remove the statistics of IPv6 multicast routes.

**clear ipv6 mroute statistics** { \* | *v6group-address* [*v6source -address*]

| Parameter Description | Parameter               | Description                                                      |
|-----------------------|-------------------------|------------------------------------------------------------------|
|                       | *                       | Removes all the forwarding entries in the multicast route table. |
|                       | <i>v6group-address</i>  | Group IPv6 address of IPv6 multicast routes                      |
|                       | <i>v6source-address</i> | Source IPv6 address of multicast route                           |

**Command Mode** Privileged EXEC mode

**Usage Guide** This command allows you to clear the statistics information of IPv6 multicast routes.

**Configuration** The following example clears all the statistical information of the multicast routing entries.

**Examples** Ruijie# clear ip mroute statistics \*

| Related | Command | Description |
|---------|---------|-------------|
|         |         |             |

|                 |                          |                                                      |
|-----------------|--------------------------|------------------------------------------------------|
| <b>Commands</b> | <b>show ipv6 mroute</b>  | Displays the multicast route forwarding information. |
|                 | <b>clear ipv6 mroute</b> | Clears the multicast route forwarding information.   |

## 2.3 ipv6 mroute

Use this command to configure static IPv6 multicast routes. Use the **no** form of this command to restore the default setting.

**ipv6 mroute** *ipv6-prefix/prefix-length* [*protocol as-number*] { *v6rpf-address* | *interface-type interface-number* } [*distance*]

**no ipv6 mroute** *ipv6-prefix/prefix-length* [*protocol as-number*] { *v6rpf-address* | *interface-type interface-number* } [*distance*]

### Parameter Description

| Parameter                              | Description                                                                                                                    |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv6-prefix/prefix-length</i>       | Source IPv6 address of the multicast route.                                                                                    |
| <i>mask</i>                            | Mask of the source IPv6 address.                                                                                               |
| <i>protocol</i>                        | (Optional) The unicast routing protocol being used.                                                                            |
| <i>v6rpf-address</i>                   | Incoming interface of the multicast route                                                                                      |
| <i>interface-type interface-number</i> | Interface type and interface ID.                                                                                               |
| <i>distance</i>                        | Management distance used to determine whether to use the route for RPF routing, ranging from 1 to 255. The default value is 0. |

**Defaults** The static IPv6 multicast routing is not configured by default.

**Command Mode** Global configuration mode.

### Usage Guide

This command is used to configure the route for the purpose of RPF check. Note that the configured route is prior to the route learned in the unicast form.

If the outgoing direction of static multicast route but not the next-hop IP shall be specified, the outgoing direction must be of the point-to-point type.

The RPF rule is that when a best multicast route from the multicast list is selected, if the BGP multicast route and the static multicast route coexist, the latter one takes the precedence; select a best unicast route from the unicast list and compare the mask length of the best multicast and unicast routes, the one with greater mask length becomes the RPF route; if both mask length are the same, you shall compare the distance, and the one with smaller distance becomes the RPF route; if both distance values are the same, the multicast route becomes the RPF route.

**Configuration Examples** The following example allows the static multicast route 2233::/64 to pass 3333::3333:

```
Ruijie(config)# ipv6 mroute 2233::/64 3333::3333
```

## 2.4 ipv6 multicast boundary

Use this command to configure the boundary of an IPv6 multicast group. Use the **no** form of this command to restore the default setting.

**ipv6 multicast boundary** *access-list-name*

**no ipv6 multicast boundary** *access-list-name*

| Parameter   | Parameter               | Description                                         |
|-------------|-------------------------|-----------------------------------------------------|
| Description | <i>access-list-name</i> | Access list associated with the multicast boundary. |

**Defaults** The boundary of a specified IPv6 multicast group is not defined by default.

**Command Mode** Interface configuration mode

Note that the ACL associated with the multicast boundary is either standard ACL or extended ACL. But the extended ACL only match the destination IPv6 address.

### Usage Guide

This command filters MLD, PIM-SMv6 packets of the specified IPv6 address range. Multicast packets will not be received and sent through the interface of the boundary.

The following example configures svi1 as the boundary of all IPv6 multicast groups.

### Configuration

### Examples

```
Ruijie(config)# ip access-list mul-boun
Ruijie(config-std-nacl)# permit ip 233.3.3.0 0.0.0.255
Ruijie(config-std-nacl)#exit
Ruijie(config)# interface vlan 1
Ruijie(config-if)# ip multicast boundary mul-boun
```

## 2.5 ipv6 multicast route-limit

Use this command to limit the number of the entries that can be added to the IPv6 multicast routing table.

Use the **no** form of this command to restore the default setting.

**ipv6 multicast route-limit** *limit* [*threshold*]

**no ipv6 multicast route-limit** *limit* [*threshold*]

| Parameter   | Parameter        | Description                                                                                     |
|-------------|------------------|-------------------------------------------------------------------------------------------------|
| Description | <i>limit</i>     | The number of the entries that can be added to the IPv6 multicast routing table is 1 to 65,536. |
|             | <i>threshold</i> | (Optional) Number of IPv6 multicast routes at which alarms will be triggered.                   |

### Defaults

The default value of *limit* is 1,024.

The default value of *threshold* is 65,536.

**Command Mode** Global configuration mode

This command is used to restrict the number of route adding to the IPv6 multicast table.

The hardware resources of different devices are limited. The routes exceeding the hardware resource will be forwarded by software, which leads to lower product performance.

**Usage Guide**

Packets that exceed this value will be discarded.. If you want to use the PIM protocol to create more than 128 entries in the multicast routing table, you are advised to set the CPP value of PIM packets to the number of entries in the multicast routing table. If you want to use the IGMP protocol to create more than 1000 entries in the multicast routing table, you are advised to set the CPP value of IGMP packets to the number of entries in the multicast routing table.

**Configuration** The following example sets the route limit to 500 and the warning value 90.

**Examples**

```
Ruijie(config)# ipv6 multicast route-limit 500 90
```

## 2.6 ipv6 multicast-routing

Use this command to enable the IPv6 multicast routing forwarding.

Use the **no** form of this command to restore the default setting.

**ipv6 multicast-routing**

**no ipv6 multicast-routing**

**Parameter**

**Description**

**Parameter**

N/A

**Description**

N/A

**Defaults**

This function is disabled by default

**Command Mode** Global configuration mode

Use this command to enable the IPv6 multicast routing forwarding. With this function disabled, the multicast protocol cannot be enabled.

**Usage Guide**

This command must be configured to enable the IPv6 multicast routing forwarding. This function conflicts with IGMP Snooping.

**Configuration** The following example enables the IPv6 multicast routing forwarding.

**Examples**

```
Ruijie(config)# ipv6 multicast-routing
```

## 2.7 ipv6 multicast rpf longest-match

Use the RPF rule to select the static multicast route, MBGP route and the unicast route for the purpose of RPF check from the static multicast route list, the MBGP route list and the unicast route list.

Use this command to select one route with the longest-matched mask from the above-mentioned three routes. If the priority values of all three routes are the same, the routes will be selected in order of static multicast route, MBGP route and unicast route.

Use the **no** form of this command to restore the default setting.

**ipv6 multicast rpf longest-match**

**no ipv6 multicast rpf longest-match**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** Use the RPF rule to select the static multicast route, MBGP route and the unicast route for the purpose of RPF check from the static multicast route list, the MBGP route list and the unicast route list.

Use this command to select one route, which is prior to the other two routes, with the longest-matched mask from the above-mentioned three routes. If the priority values of all three routes are the same, the routes will be selected in order of static multicast route, MBGP route and unicast route.

**Command**

**Mode** Global configuration mode

**Usage**

**Guide** N/A.

**Configuration Examples** The following example selects one route with the longest-matched mask from the above-mentioned three routes.

```
Ruijie(config)# ipv6 multicast rpf longest-match
```

## 2.8 ipv6 multicast static

Use this command to enable flow control for multicast packets on the Layer 2 interface. Use the **no** form of this command to restore the default setting.

**ipv6 multicast static** *source-address group-address interface-type interface-number*

**no ipv6 multicast static** *source-address group-address interface-type interface-number*

| Parameter   | Parameter             | Description                         |
|-------------|-----------------------|-------------------------------------|
| Description | <i>source-address</i> | Source IPv6 address                 |
|             | <i>group-address</i>  | IPv6 address of the multicast group |

|                                        |                                                                     |
|----------------------------------------|---------------------------------------------------------------------|
| <i>interface-type interface number</i> | Layer 2 interface on which multicast packets are allowed to forward |
|----------------------------------------|---------------------------------------------------------------------|

**Defaults** This function is disabled by default.

**Command**

**Mode** Global configuration mode

You can configure more than one command (or more than one interface) for a multicast flow. With flow control enabled, the multicast flow can only be forwarded through these configured interfaces.

**Usage Guide** This command controls the forwarding of multicast flows on an interface without any direct influence on the packet processing of multicast protocols. However, the action of a multicast protocol (for instance, PIM-SMv6) may be affected because some features of the multicast protocol are driven by multicast flows.

**Configuration Examples** The following example configures forwarding multicast flows (2222::3333, ff66::100) through GigabitEthernet 2/6 and FastEthernet 3/2.

```
Ruijie(config)# ipv6 multicast static 2222::3333 ff66::100 G2/6
Ruijie(config)# ipv6 multicast static 2222::3333 ff66::100 F3/2
```

## 2.9 msf6 nsf

Use this command to configure parameters for multicast non-stop forwarding.

Use the **no** form of this command to restore the default setting.

**msf6 nsf { convergence-time *time* | leak *interval* }**

**no msf6 nsf { convergence-time | leak }**

| Parameter<br>Description | Parameter                              | Description                                                                                                                             |
|--------------------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
|                          | <b>convergence-time</b><br><i>time</i> | Maximum duration for which the system waits for multicast protocol convergence.<br>The unit is second. The value ranges from 0 to 3600. |
|                          | <b>leak</b> <i>interval</i>            | Interval at which multicast packets are leaked.<br>The unit is second. The value ranges from 0 to 3600.                                 |

**Defaults** The default convergence-time is 20 and leak interval is 30.

**Command**

Global configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the maximum duration for which the system waits for multicast protocol convergence:

**Examples**

```
Ruijie (config)# msf6 nsf convergence-time 300
```

The following example sets the interval at which multicast packets are leaked.

```
Ruijie(config)# msf6 nsf leak 200
```

**Description**

## 2.10 show ipv6 mroute

Use this command to display the IPv6 multicast forwarding table.

**show ipv6 mroute** [*group-or-source-address* [ *group-or-source-address* ]] [**dense** | **sparse**] [**summary** | **count**]

| Parameter<br>Description | Parameter               | Description                                          |
|--------------------------|-------------------------|------------------------------------------------------|
|                          | <i>v6group-address</i>  | Multicat group IPv6 address                          |
|                          | <i>v6source-address</i> | Multicast source IPv6 address                        |
|                          | <b>summary</b>          | Displays the summary of the multicast routing table. |
|                          | <b>count</b>            | Displays the count of the multicast routing table.   |

**Command**

**Mode** Privileged EXEC mode

The following example displays all information of the IPv6 multicast routing table:

```
Ruijie# show ipv6 mroute
IPv6 Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(2222::1234, ff56::1234), uptime 00:00:31, stat expires 00:02:59
Owner PIM-SMv6, Flags: TF
Incoming interface: FastEthernet 2/1
Outgoing interface list:
FastEthernet 1/3
```

The following example displays the count of the routing table:

```
Ruijie# show ipv6 mroute count
IPv6 Multicast Statistics
Total 1 routes using 168 bytes memory
Route limit/Route threshold: 1024/2147483647
Total NOCACHE/WRONGVIF/WHOLEPKT recv from fwd: 77/147/0
Total NOCACHE/WRONGVIF/WHOLEPKT sent to clients: 77/147/0
Immediate/Timed stat updates sent to clients: 0/29
Reg ACK recv/Reg NACK recv/Reg pkt sent: 0/0/0
Next stats poll: 00:00:09
Forwarding Counts: Pkt count/Byte count, Other Counts: Wrong If pkts
Fwd msg counts: WRONGVIF/WHOLEPKT recv
Client msg counts: WRONGVIF/WHOLEPKT/Imm Stat/Timed Stat sent
Reg pkt counts: Reg ACK recv/Reg NACK recv/Reg pkt sent
(2222::1234, ff56::1234), Forwarding: 1/0, Other: 0
Fwd msg: 0/0, Client msg: 0/0/0/0, Reg: 0/0/0
```

#### Configuration Examples

The following example displays the summary of the routing table:

```
Ruijie# show ipv6 mroute summary
IPv6 Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(2222::1234, ff56::1234), 00:00:28/00:03:25, PIM-SMv6, Flags: TF
```

## 2.11 show ipv6 mroute static

Use this command to display the static IPv6 multicast routing information.

**show ipv6 mroute static**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Command****Mode** Privileged EXEC mode

**Usage** This command is used to display the statically-configured multicast route. Under the same condition, the static multicast route is prior to the unicast route.

**Guide**

The following example displays the static IPv6 multicast routing information.

**Configuration** Ruijie#show ipv6 mroute static

**Examples** Mroute: 2233::/64, RPF neighbor: 3333::3333

Protocol: , distance: 0

## 2.12 show ipv6 mvif

Use this command to display the basic information of the multicast interface.

**show ipv6 mvif** { *interface-type interface-number* }

| Parameter   | Parameter                              | Description               |
|-------------|----------------------------------------|---------------------------|
| Description | <i>interface-type interface-number</i> | Interface Type and number |

**Command****Mode** Privileged EXEC mode

The following example displays the basic information of the multicast interface of svil.

**Configuration** Ruijie#show ipv6 mvif

**Examples**

| Interface | Mif    | Owner     | Uptime    |
|-----------|--------|-----------|-----------|
| Idx       | Module |           |           |
| Register  | 0      | 03d03h09m |           |
| VLAN 1    | 1      | PIMSMV6   | 03d03h09m |

## 2.13 show ipv6 rpf

Use this command to display the RPF information of the specified source IPv6 address.

**show ipv6 rpf** {*v6source-address*}

| Parameter   | Parameter               | Description                   |
|-------------|-------------------------|-------------------------------|
| Description | <i>v6source-address</i> | Specified source IPv6 address |

**Command****Mode** Privileged EXEC mode

**Configuration** The following example displays the information of the RPF to 2222::3333:

**Examples**

```
Ruijie# show ipv6 rpf 2222::3333
RPF interface: GigabitEthernet 0/1
RPF neighbor: ::
RPF route: 2222::/64
RPF type: unicast (connected)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 0
Metric: 0
```

## 2.14 show ipv6 mrf6 mfc

Use this command to display the IPv6 multicast forwarding table.

**show ipv6 mrf6 mfc** [ *v6source-address* *v6group-address* ]

| Parameter   | Parameter               | Description                         |
|-------------|-------------------------|-------------------------------------|
| Description | <i>v6group-address</i>  | IPv6 address of a multicast group.  |
|             | <i>v6source-address</i> | IPv6 address of a multicast source. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display the entries of the multicast data stream forwarding table. The forwarding table displayed in the command output is basically consistent with the multicast routing forwarding table displayed in the command output of **show ipv6 mroute**. The difference is that in the multicast data stream forwarding table, the protocols based on which entries are generated are not recorded.

The two parameters are optional. The source address and group address must be specified together. If the two parameters are not specified, all mrf table entries will be displayed.

If the two parameters are specified, the mrf entries of the specified source address and group address are displayed.

**Configuration Examples** The following example displays the layer-3 multicast forwarding table entries of IPv6 (the source address is 2000::1 and the group address is FF55::1).

```
Ruijie#show ipv6 mrf6 mfc 2000::1 FF55::1
Multicast Routing and Forwarding Cache6 Table
(2000::1, FF55::1)
FAST_SW, SWTCHED, MIN_MTU: 1500, MIN_MTU_IFINDEX: 4099, WRONG IF: 0
Incoming interface: VLAN 1[4097]
Outgoing interface list:
VLAN 3 (1)
```

| Field           | Description                                                                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000::1         | Source address of entries.                                                                                                                                                                                                                                                                             |
| FF55::1         | Group address of entries.                                                                                                                                                                                                                                                                              |
| FAST_SW         | Indicates whether the entries allow fast forwarding, that is, whether the entries can be forwarded by using hardware or software forwarding. If the entries include an interface that does not support the multicast function (for example, the GRE tunnel interface), fast forwarding is not allowed. |
| SWTCHED         | Indicates whether the entries have been placed in the forwarding table on the next layer.                                                                                                                                                                                                              |
| MIN_MTU MTU     | Minimum MTU value of entries.                                                                                                                                                                                                                                                                          |
| MIN_MTU_IFINDEX | Index of the interface that has the minimum MTU value.                                                                                                                                                                                                                                                 |
| WRONG IF        | Number of multicast packets sent from the wrong inbound interface.                                                                                                                                                                                                                                     |
| VLAN 1[4097]    | Indicates that the rpf inbound interface is VLAN1. 4097 indicates the IFINDEX of the interface.                                                                                                                                                                                                        |
| VLAN 3 (1)      | Indicates that the layer-3 outbound interface of the entries is VLAN 3. 1 indicates the ttl threshold of the layer-3 interface.                                                                                                                                                                        |

**Description**

## 2.15 show msf6 msc

Use this command to display entries of the IPv6 routing multicast data stream exchange table.

**show msf6 msc** [ *v6source-address* ] [ *v6group-address* ] [ *vlan-id* ]

**Parameter  
Description**

| Parameter               | Description                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>v6group-address</i>  | IPv6 address of a multicast group.                                                                                           |
| <i>v6source-address</i> | IPv6 address of a multicast source.                                                                                          |
| <i>vlan-id</i>          | VLAN ID of the inbound interface of the entries.<br>If the value is greater than 4096, the interface is a routing interface. |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** This command is used to display entries of the IPv6 routing multicast data stream exchange table. The three parameters are all optional.  
If only the source address is specified and set to s1, msc entries of this source address will be

displayed.

If the source address is set to s1 and the group address is set to g1, msc entries of this source address and group address will be displayed.

If the source address is set to s1, the group address is set to g1, and the VLAN ID is set to v1, then msc entries that meet these three conditions will be displayed.

You must specify these three parameters in sequence. That is, you must specify the current parameter before specifying the next.

**Configuration Examples** The following example displays entries of the IPv6 routing multicast data exchange table of source address 2000::1:

```
Ruijie# show msf6 msc 2000::1
Multicast Switching Cache Table
(2000::1, FF55::1, 1), SYNC, MTU:0, 1 OIFs
  VLAN 4094(8190): 1 OPORTs, REQ: DONE
  OPORT 6, MLD-SNP, REQ: DONE
```

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000::1         | Source address of entries.                                                                                                                                                                                                                                                                                                                                                                                 |
| FF55::1         | Group address of entries.                                                                                                                                                                                                                                                                                                                                                                                  |
| 1               | VLAN ID of the inbound interface of the entries.                                                                                                                                                                                                                                                                                                                                                           |
| SYNC            | Indicates that the entries have been synchronized to the bottom-layer hardware.                                                                                                                                                                                                                                                                                                                            |
| MTU             | MTU value of the entries.                                                                                                                                                                                                                                                                                                                                                                                  |
| OIFs            | Number of layer-3 interfaces of the entries.                                                                                                                                                                                                                                                                                                                                                               |
| VLAN 4094(8190) | Indicates a layer-3 outbound interface VLAN xxx (yyy). If the layer-3 interface is an SVI interface, the value of xxx is the VLAN vid of the SVI, and the value of yyy is the VLAN vid+4096. If the layer-3 interface is a routing interface, the value of xxx is the IFINDEX of the interface+4096, and the value of yyy is the IFINDEX. This facilitates the index management of all layer-3 interfaces. |
| 1 OPORTs        | Number of layer-2 interfaces owned by this layer-3 exit oif.                                                                                                                                                                                                                                                                                                                                               |
| REQ: DONE       | Indicates that the oif has been set to the bottom-layer hardware. The value may be:<br>Waiting to be added. Usually it is waiting for a data stream to be triggered.<br>DEL: Being deleted.<br>DONE: Synchronized to the hardware.                                                                                                                                                                         |
| OPORT 6         | Indicates that the oif has a layer-2 interface with the interface number of 6.                                                                                                                                                                                                                                                                                                                             |
| MLD-SNP         | Indicates that the interface is created based on MLD SNOOPING. Alternatively, the value may be one of the following options:<br>ROUTER: Indicates that the interface is created based on the layer-3 protocol.<br>INHERIT_FM_MLD_SNP: Indicates that the interface is created based on the MLD SNOOPING protocol inherited from other entries.                                                             |
| REQ: DONE       | Indicates that the interface has been set to the bottom-layer hardware. The value may be:<br>ADD: Waiting to be added. Usually it is waiting for a data stream to be triggered.<br>DEL: Being deleted.<br>DONE: Synchronized to the hardware.                                                                                                                                                              |

**Description**

## 2.16 show msf6 nsf

Use this command to display the multicast non-stop forwarding configuration.

**show msf6 nsf**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the multicast non-stop forwarding configuration.

**Examples**

```
Ruijie# show msf6 nsf
Multicast HA Parameters
-----+-----
protocol convergence timeout    120 secs
flow leak interval              20 secs
```

**Description**

## 3 IGMP Commands

### 3.1 clear ip igmp group

Use this command to clear dynamic group member information obtained from the response messages in the IGMP buffer.

**clear ip igmp group** [ *group-address* [ *interface-type interface-number* ] ]

| Parameter Description | Parameter               | Description                                                                                                                            |
|-----------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>group-address</i>    | 32-bit multicast group IP address, namely Category D address. 8 bits are in one group in decimal form. Groups are separated with dots. |
|                       | <i>interface-type</i>   | Interface type                                                                                                                         |
|                       | <i>interface-number</i> | Interface number                                                                                                                       |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** The IGMP buffer includes a list that contains the multicast groups that the hosts in the direct subnet join. If the device joins a group, this group will be included in this list. To delete all the entries from the IGMP buffer, use the **clear ip igmp group** command without parameters.

**Configuration** The following example clears all group entries.

**Examples** Ruijie# clear ip igmp group

| Related Commands | Command                | Description |
|------------------|------------------------|-------------|
|                  | show ip igmp groups    | N/A         |
|                  | show ip igmp interface | N/A         |

**Platform** N/A

**Description**

### 3.2 clear ip igmp interface

Use this command to clear the IGMP entry for the interface.

**clear ip igmp interface** *interface-type interface-number*

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           |             |

|                         |                  |
|-------------------------|------------------|
| <i>interface-type</i>   | Interface type   |
| <i>interface-number</i> | Interface number |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to clear the information on the interface that is generated when IGMP is configured.

**Configuration** The following example clears the IGMP entry for the interface.

**Examples** Ruijie# clear ip igmp interface gigabitEthernet 4/1

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform**

**Description** N/A

### 3.3 ip igmp access-group

Use this command to control a multicast group on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp access-group** *access-list*

**no ip igmp access-group**

**default ip igmp access-group**

| Parameter Description | Parameter   | Description                                                                          |
|-----------------------|-------------|--------------------------------------------------------------------------------------|
|                       | access-list | Name of access control list in the range from 1 to 199, 1300 to 2699, or characters. |

**Defaults** This command is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** You can add several multicast groups into the specific interfaces of the host in a subnet. These multicast groups can be controlled using **ip igmp access-group**.

 With the IGMPv3 enabled, when the multicast group accesses the control command, the

extended ACL is associated. If the IGMP report information received is (S1,S2,S3...Sn,G), the corresponding ACL will be used by this command to the (0, G) for the matching check. In order to use this command normally, the (0,G) must be configured explicitly for the extended ACL so as to implement the normal filtering of (S1, S2, S3...Sn,G).

**Configuration** The following example adds the interface Ethernet 0/1 to the group 225.2.2.2 .

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# access-list 1 permit 225.2.2.2 0.0.0.0
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ip igmp access-group 1
```

The following example associates the group control list with the extended ACL on the interface Eth 0/1 which only processes the igmp protocol packets with source address 1.1.1.1 and group address 233.3.3.3.

```
Ruijie# configure terminal
Ruijie(config)# ip access-list extended ext_acl
Ruijie(config-ext-nacl)# permit ip host 1.1.1.1 host 233.3.3.3
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ip igmp access-group ext_acl
```

**Platform** N/A  
**Description**

### 3.4 ip igmp immediate-leave group-list

In the IGMPversion2 and IGMPversion3 versions, use this command to shorten the delay of leaving a group. This command is used when a single receiving host is connected to a single interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp immediate-leave group-list** *access-list*

**no ip igmp immediate-leave**

**default ip igmp immediate-leave**

**Parameter  
Description**

| Parameter   | Description                 |
|-------------|-----------------------------|
| access-list | Name of access control list |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** If this command is not configured, the device will send a particular group query message upon receiving the leaving message from the interface. When the host response is timeout, the device stops forwarding packets to this interface. The length of timeout depends on the query interval of the last member and IGMP robustness variable. The default value is 2s.

If this command is configured, the device does not send a particular group query message upon receiving the leaving message from the interface. Instead, it directly removes this interface from the IGMP buffer and notifies the IGMP protocol. This will shorten the time significantly.

**Configuration Examples** The following example provides the immediate leaving function for some multicast groups. Certainly, you must make sure each interface of these multicast groups have one group member only.

```
Ruijie# configure terminal
Ruijie(config)# access-list 1 permit 225.192.20.0 0.0.0.255
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ip igmp immediate-leave group-list 1
Ruijie(config-if)# exit
```

**Platform** N/A

**Description**

### 3.5 ip igmp join-group

Use this command to configure the interface of the switch with host activities and adds it to a multicast group, so that the sub-switch can learn the corresponding group information. You can use this command to add an interface to a group.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp join-group** *group-address*

**no ip igmp join-group** *group-address*

**default ip igmp join-group** *group-address*

**Parameter  
Description**

| Parameter     | Description                |
|---------------|----------------------------|
| group-address | Multicast group IP address |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command enables the host activities for the IGMP interface. When the host function is enabled, the interface can initiate the report message and respond to the query message.

If the IGMP function is enabled on the interface, the interface can initiate the report message, so that the interface can learn the configured group members.

You can use this command to add an interface to a group.

**Configuration** The following example adds a host group member manually.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fast 0/1
Ruijie(config-if)# ip igmp join-group 233.3.3.3
```

**Description**

## 3.6 ip igmp last-member-query-count

Use this command to configure the value of **last-member-query-count**.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp last-member-query-count** *number*

**no ip igmp last-member-query-count**

**default ip igmp last-member-query-count**

| Parameter<br>Description | Parameter | Description                                                    |
|--------------------------|-----------|----------------------------------------------------------------|
|                          | number    | Value of the last member query count in the range from 2 to 7. |

**Defaults** The default is 2.

**Command Mode** Interface configuration mode

**Usage Guide** When the interface of the device receives an IGMPv2 group leaving message, the device waits for duration of query interval multiplying **last-member-query-count** time. The device will delete information about this group member if no group member report is received within the waiting time.

**Configuration** The following example sets the value of last member query count to 3.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0
Ruijie(config-if)# ip igmp last-member-query-count 3
```

Description

### 3.7 ip igmp last-member-query-interval

Use this command to set the time interval of sending the group query message.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp last-member-query-interval** *interval*

**no ip igmp last-member-query-interval**

**default ip igmp last-member-query-interval**

| Parameter<br>Description | Parameter | Description                                                                                        |
|--------------------------|-----------|----------------------------------------------------------------------------------------------------|
|                          | interval  | The interval sending the group query message in the range from 1 to 255 in the unit of 0.1 second. |

Defaults The default is 10.

Command Interface configuration mode  
Mode

**Usage Guide** When the interface of the device receives an IGMPv2 group leaving message, the device waits for duration of query interval multiplying **last-member-query-count** time. The device will delete information about this group member if no group member report is received within the waiting time.

**Configuration** The following example sets the interval of sending the group query message to 20 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface eth 0
Ruijie(config-if)# ip igmp last-member-query-interval 200
```

Description

### 3.8 ip igmp limit

Use this command to globally set the maximum number of IGMP group records.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp limit** *number* [ **except** *access-list* ]

**no ip igmp limit**

**default ip igmp limit**

#### Parameter Description

| Parameter          | Description                                                                        |
|--------------------|------------------------------------------------------------------------------------|
| <i>number</i>      | Maximum number of IGMP states, depending on devices                                |
| <b>except</b>      | (Optional) Prevents the groups of the access list from taking part in calculation. |
| <i>access-list</i> | (Optional) Access list name                                                        |

#### Defaults

The default is 65536.

#### Command Mode

Global configuration mode/ Interface configuration mode

#### Usage Guide

Use this command to globally configure the maximum number of IGMP group records. The messages of the members exceeding the threshold will not be saved in the IGMP buffer and will not be forwarded.

This command can be configured globally or on the interface. The messages of the members will be ignored if they exceed the interface or global configuration.

#### Configuration

The following example sets the maximum number to 300.

#### Examples

```
Ruijie(config) # ip igmp limit 300
```

#### Description

### 3.9 ip igmp mroute-proxy

Use this command to configure an interface as a mroute-proxy interface that can transmit messages to its uplink ports.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp mroute-proxy** *interfname*

**no ip igmp mroute-proxy**  
**default ip igmp mroute-proxy**

| Parameter<br>Description | Parameter         | Description                           |
|--------------------------|-------------------|---------------------------------------|
|                          | <i>interfname</i> | Name of the relevant uplink interface |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** After an uplink interface is configured as **proxy-service** interface, the interface can forward the IGMP messages sent by other members.

**Configuration Examples** The following example configures an interface to **mroute-proxy** interface.

```
Ruijie(config-if)# ip igmp mroute-proxy fa 0/1
```

**Platform Description** N/A

### 3.10 ip igmp proxy-service

Use this command to enable the service function of all downlink **mroute-proxy** ports. If you run this command on an interface, the interface becomes the uplink port of the corresponding **mroute-proxy** that associates its downlink ports and maintains the group information reported by the downlink ports. Use the **no** or **default** form of this command to restore the default setting.

**ip igmp proxy-service**  
**no ip igmp proxy-service**  
**default ip igmp proxy-service**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The command can configure at most 32 proxy-service ports. The number of interface with IGMP Proxy enabled is limited by the supported multicast interface number. When receiving a query message, the **proxy-service** port responds according to the IGMP group member information maintained by the port itself. The member information maintained by the **proxy-service** port is collected from the interface configured with **mroute-proxy**. Therefore, if a port is configured with proxy-service, the port performs the host activities, but not the device activities.

If **switch port** operation is performed on an interface with proxy-service command configured, the **ip igmp mroute-proxy interface** command configured on the associated downlink ports is automatically deleted.

**Configuration** The following example configures an interface to the **proxy-service** module.

**Examples** Ruijie(config-if)# ip igmp proxy-service

### 3.11 ip igmp query-interval

Use this command to configure the query interval of an ordinary member.

Use the **no** or default form of this command to restore the default setting.

**ip igmp query-interval** *seconds*

**no ip igmp query-interval**

**default ip igmp query-interval**

**Parameter Description**

| Parameter | Description                                                                                |
|-----------|--------------------------------------------------------------------------------------------|
| seconds   | Query interval of ordinary member, in the range is from 1 to 18000 in the unit of seconds. |

**Defaults** The default is 125 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** The time to query an ordinary member can be changed by configuring the query interval of the ordinary member.

**Configuration** The following example configures the query interval of ordinary member to 120 seconds on the

**Examples**

interface Ethernet 0.

```
Ruijie(config-if)# ip igmp query-interval 120
```

The following example c configures the query interval of ordinary member to the default value on the interface Ethernet 0.

```
Ruijie(config-if)# no ip igmp query-interval
```

## 3.12 ip igmp query-max-response-time

Use this command to configure the maximum response interval.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp query-max-response-time** *seconds*

**no ip igmp query-max-response-time**

**default ip igmp query-max-response-time**

**Parameter  
Description**

| Parameter | Description                                                      |
|-----------|------------------------------------------------------------------|
| seconds   | The maximum response interval, in the range from 1 to 25 seconds |

**Defaults**

The default is 10 seconds.

**Command  
Mode**

Interface configuration mode

**Usage Guide**

This command controls the interval for the respondent to respond the query message before the device deletes the group information.

**Configuration**

The following example configures the maximum response interval to 20s on the interface Ethernet 0.

**Examples**

```
Ruijie(config-if)# ip igmp query-max-response-time 20
```

The following example configures the maximum response interval to the default value on the interface Ethernet 0.

```
Ruijie(config-if)# no ip igmp query-max-response-time
```

### 3.13 ip igmp query-timeout

Use this command to configure the time the device waits before it takes over as the querier.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp query-timeout** *seconds*

**no ip igmp query-timeout**

**default ip igmp query-timeout**

| Parameter<br>Description | Parameter | Description                                                                                                    |
|--------------------------|-----------|----------------------------------------------------------------------------------------------------------------|
|                          | seconds   | Time the device waits before it takes over as the querier, in the range from 60 to 300 in the unit of seconds. |

**Defaults** The default is 255 seconds.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** IGMPv2 should be run for this command to work. By default, Cisco sets the waiting time of the device to two times of the query interval of **ip igmp query-interval**. In Ruijie, the default value is set to 255s. This device becomes the querier if no query packet is received in this duration.

**Configuration Examples** The following example configures the time the device waits before it takes over as the querier to 200s on the interface Ethernet 0/1.

```
Ruijie(config-if)# ip igmp query-timeout 200
```

The following example configures the time the device waits before it takes over as the querier to the default value on the interface Ethernet 0/1.

```
Ruijie(config-if)# no ip igmp query-timeout
```

### 3.14 ip igmp robustness-variable

Use this command to change the value of the robustness variable.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp robustness-variable** *number*

**no ip igmp robustness-variable**

**default ip igmp robustness-variable**

| Parameter<br>Description | Parameter | Description                                                |
|--------------------------|-----------|------------------------------------------------------------|
|                          | number    | The value of robustness variable, in the range from 2 to 7 |

**Defaults** The default is 2.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the value of robustness variable to 3.

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0
Ruijie(config-if)# ip igmp robustness-variable 3
```

### 3.15 ip igmp ssm-map enable

Use this command to enable the **igmp ssm-map** function in the global configuration mode.

Use the **no** form of this command to restore the default setting.

**ip igmp ssm-map enable**

**no ip igmp ssm-map enable**

**default ip igmp ssm-map enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** If this command is configured, the dynamically learned group information is added forcibly to the associated source record. This command is usually used together with the **ip igmp ssm-map static** command.

**Configuration** The following example enables the **igmp ssm-map** function in the global configuration mode.

**Examples** Ruijie(config)# ip igmp ssm-map enable.

**Related  
Commands**

## 3.16 ip igmp ssm-map static

Use this command to map the static **ssm-map** source IP address to the group records in the global mode.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp ssm-map static** *access-list a.b.c.d*

**no ip igmp ssm-map static** *access-list a.b.c.d*

**default ip igmp ssm-map enable**

**Parameter  
Description**

| Parameter          | Description                                                |
|--------------------|------------------------------------------------------------|
| <i>access-list</i> | ACL name in the range 1 to 99, 1300 to 1999 or characters. |
| <i>a.b.c.d</i>     | Unicast address mapped to the group record.                |

**Defaults** This function is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** This command is used together with the **ip igmp ssm-map enable** command. After configuration, the port maps the corresponding source IP address to all received messages below **v3**.

**Configuration** The following example maps the source address 192.168.2.2 to all group records permitted by ACL 11.

**Examples**

Ruijie(config)# ip igmp ssm-map static 11 192.168.2.2.

Description

### 3.17 ip igmp static-group

Use this command to directly add an interface to a group.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp static-group** *group-address*

**no ip igmp static-group** *group-address*

**default ip igmp static-group** *group-address*

| Parameter<br>Description | Parameter            | Description                |
|--------------------------|----------------------|----------------------------|
|                          | <i>group-address</i> | Multicast group IP address |

**Defaults** The switch is not added to a multicast group by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command directly adds an interface to a multicast group. The difference from **join-group** is that it directly adds an interface to the group without interacting with a report message.  
You can use this command to add an interface to a group.

**Configuration Examples** The following example adds a host group member manually.

```
Ruijie# configure terminal
Ruijie(config)# interface fast 0/1
Ruijie(config-if)# ip igmp static-group 233.3.3.3
```

### 3.18 ip igmp version

Use this command to set the version number of IGMP to be used on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp version { 1 | 2 | 3 }**

**no ip igmp version**

**default ip igmp version**

**Parameter  
Description**

| Parameter     | Description                                     |
|---------------|-------------------------------------------------|
| { 1   2   3 } | Three version numbers, in the range from 1 to 3 |

**Defaults**

The default is 2.

**Command  
Mode**

Interface configuration mode

**Usage Guide**

Use this command to globally configure the IGMP version. It should be noted that IGMP will reset after configuration.

**Configuration**

The following example sets the version number to 2.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0
Ruijie(config-if)# ip igmp version 2
```

## 3.19 ip igmp enforce-router-alert

Use this command to receive IGMP report packets with the option of router-alert.

**ip igmp enforce-router-alert**

Use the **no** form of this command to receive all IGMP report packets.

**no ip igmp enforce-router-alert**

Use the **default** form of this command to restore the default setting.

**default ip igmp enforce-router-alert**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** All IGMP report packets are received by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example receives IGMP report packets with the option of router-**alert**.

```
Ruijie# configure terminal
Ruijie(config)#ip igmp enforce-router-alert
```

**Platform** N/A

**Description**

## 3.20 ip igmp enforce-source-subnet

Use this command to receive only the IGMP report packet containing the source address in the same network segment as the port.

**ip igmp enforce-source-subnet**

Use the **no** form of this command to restore the default setting.

**no ip igmp enforce-source-subnet**

Use the **default** form of this command to restore the default setting.

**default ip igmp enforce-source-subnet**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The source IP address is not checked by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example receives only the IGMP report packet containing the source address in the same network segment as the port.

```
Ruijie# configure terminal
Ruijie(config)# ip igmp enforce-source-subnet
```

**Platform** N/A

**Description**

### 3.21 ip igmp send-router-alert

Use this command to send IGMP report packets with the Router Alert option.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp send-router-alert**

**no ip igmp send -router-alert**

**default ip igmp send -router-alert**

| Parameter<br>Description  | Parameter                                                                                                                                                        | Description |

### 3.22 show ip igmp groups

Use this command to display the groups directly connected to the device and the group information learnt from IGMP.

**show ip igmp groups** [ *group-address* | *interface-type* ]  
*interface-number*] [ **detail** ]

| Parameter<br>Description | Parameter               | Description                                                                                                                            |
|--------------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>group-address</i>    | 32-bit multicast group IP address, namely Category D address. 8 bits are in one group in decimal form. Groups are separated with dots. |
|                          | <i>interface-type</i>   | Interface type                                                                                                                         |
|                          | <i>interface-number</i> | Interface number                                                                                                                       |
|                          | <b>detail</b>           | Displays the detailed information                                                                                                      |
|                          | N/A                     | Displays the information about all the groups                                                                                          |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command without any parameters to display group address, interface type, and information about all the multicast groups directly connected to the interface. Information about a specific group is displayed if a group address is added to the command.

**Configuration** The following example displays information about all the groups.

**Examples**

```
Ruijie# show ip igmp groups
IGMP Connected Group Membership
Group Address  Interface  Uptime  Expires  Last Reporter
224.0.1.1     eth2      00:00:09 00:04:17 10.10.0.82
224.0.1.24     eth2      00:00:06 00:04:14 10.10.0.84
224.0.1.40     eth2      00:00:09 00:04:15 10.10.0.91
224.0.1.60     eth2      00:00:05 00:04:15 10.10.0.7
239.255.255.250 eth2      00:00:12 00:04:15 10.10.0.228
239.255.255.254 eth2      00:00:08 00:04:13 10.10.0.84
```

The following example displays detailed information about a specific group.

```
Ruijie# show ip igmp groups 224.1.1.1 detail
Interface      : eth1
Group: 224.1.1.1
Uptime: 00:00:42
Group mode: Include

## 4 MLD Commands

### 4.1 clear ipv6 mld group

Use this command to clear the dynamic group member learned by MLD protocol. The dynamic group member refers to the group member record generated by learning the report packets.

**clear ipv6 mld group** [ *group-address* ] [ *interface-type interface-number* ]

| Parameter<br>Description | Parameter               | Description                                |
|--------------------------|-------------------------|--------------------------------------------|
|                          | <i>group-address</i>    | IPv6 multicast group address with 128 bits |
|                          | <i>interface-type</i>   | The associated interface type              |
|                          | <i>interface-number</i> | The associated interface number            |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** MLD maintains a list of the multicast groups to be added to the host in the directly-connected sub-net. Use the **clear ipv6 mld group** command to remove all dynamic group member record from the MLD group member list.

**Configuration Examples** The following example clears all group records.

```
Ruijie# clear ipv6 mld group
```

The following example clears one group record.

```
Ruijie# clear ipv6 mld group ff1e::100
```

The following example s clears the record on a specified interface.

```
Ruijie# clear ipv6 mld group ff1e::100 interfa fa0/1
```

| Related<br>Commands | Command                        | Description |
|---------------------|--------------------------------|-------------|
|                     | <b>show ipv6 mld groups</b>    | N/A         |
|                     | <b>show ipv6 mld interface</b> | N/A         |

**Platform** N/A

**Description**

### 4.2 clear ipv6 mld interface

Use this command to clear all MLD statistical information and the group member records on the interface.

**clear ipv6 mld interface** *interface-type interface-number*

**Parameter  
Description**

| Parameter               | Description        |
|-------------------------|--------------------|
| <i>interface-type</i>   | The interface type |
| <i>interface-number</i> | The interface ID   |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear all group information and some packet statistical information learned by LDP on the interface. Those packet statistical information include the number of the received report packets, the number of the done packets and the the number of the group members on the interface.

**Configuration  
Examples** The following example clears all MLD statistical information and the group member records on the interface.

```
Ruijie# clear ipv6 mld interface fa 1/1
```

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform  
Description** N/A

## 4.3 ipv6 mld access-group

Use this command to filter the specific requested group on the interface. Only the report packets in accordance with the corresponding ACL are allowed to be processed.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld access-group** *access-list*

**no ipv6 mld access-group**

**default ipv6 mld access-group**

**Parameter  
Description**

| Parameter          | Description       |
|--------------------|-------------------|
| <i>access-list</i> | The IPv6 ACL name |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Use this command to filter some groups on the interface and associate with the corresponding ACLs. The correspondent ACL deny report packets will be discarded. This command supports the extended ACL and the source record information of the MLDv2 packets can be filtered.

 The multicast group access control command is associated with the extended ACL. When the received MLD report message is (S1,S2,S3...Sn,G), use this command to match and check the (0,G) message using the corresponding ACL. To this end, a (0,G) must be configured for the extended ACL to filter the (S1,S2,S3...Sn,G).

**Configuration Examples** The following example enables the group information carried in the report packets to be in accordance with acl for the normal handling on the interface Eth0/1.

```
Ruijie(config)#ipv6 access-list acl
Ruijie(config-ipv6-acl)#permit ipv6 ::/64 ff66::100/64
Ruijie(config-ipv6-acl)#permit ipv6 2222::3333/64 ff66::100/64
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ipv6 mld access-group acl
```

**Platform** N/A  
**Description**

## 4.4 ipv6 mld immediate-leave group-list

Use this command to set the immediate-leave mechanism. With this command configured, the group within the range of group-list, will not send the query packet for the specific group and will remove this group from the group member list immediately after receiving the corresponding done packets. This function is used in the condition that there is only one multicast source that receives the host request on an interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld immediate-leave group-list** access-list  
**no ipv6 mld immediate-leave group-list**  
**default ipv6 mld immediate-leave group-list**

**Parameter Description**

| Parameter   | Description       |
|-------------|-------------------|
| access-list | The IPv6 ACL name |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Without this command configured, when the device receives the MLD leave packets, the request packets for the specific groups will be sent. If there is still no host reply within the response time, the device will remove the corresponding group record from the group member list. The timeout interval is determined by the last member query interval and the MLD robustness variable, and the default value is 2s.

With this command configured, when the device receives the MLD leave packets, it will not send the request packets for the specific groups, but remove the group information immediately, which reduces the leave delay greatly in the condition that there is only one host connecting to the interface.

**Configuration** The following example configures the immediate-leave function.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)#ipv6 access-list acl
Ruijie(config-ipv6-acl)#permit ipv6 2222::3333/64 ff66::100/64
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ipv6 mld immediate-leave group-list acl
```

**Description**

## 4.5 ipv6 mld join-group

Use this command to configure the host action for the switch interface and add the related multicast group to the interface.

Use the **no** or default form of this command to restore the default setting.

**ipv6 mld join-group** *group-address*

**no ipv6 mld join-group** *group-address*

**default ipv6 mld join-group** *group-address*

**Parameter Description**

| Parameter     | Description                                     |
|---------------|-------------------------------------------------|
| group-address | The IPv6 non-management multicast group address |

**Defaults** The interface is not added to any group by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Use this command to enable the MLD host action on the interface. The interface can not only send

the packets initiatively, but also reply to the query packets.

Use this command if it is necessary to join a group member to the interface.

It is worth mentioning that if the group address whose beginning characters are 0xFF\*1,0xFF3\*, it fails to configure this command. The group address whose beginnning characters are 0xFF\*2 fails to form a group.

**Configuration** The following example adds the host group member:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fast 0/1
Ruijie(config-if)# ipv6 mld join-group ff55::100
```

**Description**

## 4.6 ipv6 mld last-member-query-count

**last-member-query-count** represents that after the interface with MLD enabled receives the done packets, the count number of the times of sending the query packets to the specific group. Use this command to set the last-member-query-count number.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld last-member-query-count** *number*

**no ipv6 mld last-member-query-count**

**default ipv6 mld last-member-query-count**

**Parameter  
Description**

| Parameter | Description                                                 |
|-----------|-------------------------------------------------------------|
| number    | The last member query count number. The valid range is 2-7. |

**Defaults**

The default is 2.

**Command  
Mode**

Interface configuration mode

**Usage Guide**

With the MLD leave packets received on the interface, if there is no group reply within the timeout interval, this group will be removed from the MLD group member list on the interface. The timeout interval is the query interval for the specific group(multiplied by the value of **mld last-member-query-count**) plus half the reply time.

**Configuration** The following example sets the last-member-query-count number to 3.

**Examples**

```
Ruijie# configure terminal
```

```
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ipv6 mld last-member-query-count 3
```

**Related  
Commands**

**Platform** N/A  
**Description**

## 4.7 ipv6 mld last-member-query-interval

Use this command to set the time interval of sending the query packets to the specific group. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld last-member-query-interval** *interval*

**no ipv6 mld last-member-query-interval**

**default ipv6 mld last-member-query-interval**

**Parameter  
Description**

| Parameter | Description                                          |
|-----------|------------------------------------------------------|
| interval  | The valid range is 1-255 in the unit of 0.1 seconds. |

**Defaults** The default is 10 seconds.

**Command  
Mode** Interface configuration mode

**Usage Guide** With the MLD leave packets received on the interface, if there is no group reply within the timeout interval, this group will be removed from the MLD group member list on the interface. The timeout interval is the query interval for the specific group(multiplied by the value of **mld last-member-query-count**) plus half the reply time.

**Configuration** The following example sets the mld last-member-query-interval to 2 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fa 0/1
Ruijie(config-if)# ipv6 mld last-member-query-interval 20
```

**Description**

## 4.8 ipv6 mld limit

Use this command to enable to learn the max-number of the group member through the MLD protocol.

Use the **no** form of this command to restore the default setting.

**ipv6 mld limit** *number* [**except** *access-list*]

**no ipv6 mld limit** *number* [**except** *access-list*]

**default ipv6 mld limit** *number* [**except** *access-list*]

### Parameter Description

| Parameter                 | Description                                               |
|---------------------------|-----------------------------------------------------------|
| number                    | The maximum number of the group member learned by the MLD |
| <b>except</b> access-list | (Optional) The ACL beyond the configured mld limit        |

### Defaults

The default is 1024.

### Command Mode

Interface configuration mode/Global configuration mode

### Usage Guide

Use this command to set the max-number of the group members learned through the MLD in the global configuration mode. If the group member number has exceeded the limit, the received report packets later will be discarded and fail to form the group record.

If the except list has also been set at the same time, the group member packets, including the packets in the access-list, will be free from the member number limit.

This command can also be used in the interface configuration mode. The configurations in two different configuration modes are independent. If the number limit in the global configuration mode is lower than the one in the interface configuration mode, the former configuration takes precedence.

**Configuration** The following example sets the MLD limit to 300.

### Examples

```
Ruijie(config-if)# ipv6 mld limit 300
```

The following example sets the MLD limit to 300, but the configured acl can still learn.

```
Ruijie(config-if)# ipv6 mld limit 300 except acl
```

### Description

## 4.9 ipv6 mld mroute-proxy

Use this command to enable the interface to forward the packets to the correspondent connected interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld mroute-proxy** *interface-type interface-number*

**no ipv6 mld mroute-proxy**

**default ipv6 mld mroute-proxy**

| Parameter<br>Description | Parameter                                        | Description                           |
|--------------------------|--------------------------------------------------|---------------------------------------|
|                          | <i>interface-type</i><br><i>interface-number</i> | The correspondent connected interface |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** After the connected interface has been configured as the proxy-service interface, it can forward the MLD packets sent from other members

**Configuration Examples** The following example sets the interface as the mroute-proxy interface.

```
Ruijie(config-if) # ipv6 mld mroute-proxy fa 0/1
```

| Related<br>Commands | Command | Description |

## 4.10 ipv6 mld proxy-service

Use this command to enable the proxy-service function for the interface connected with the mroute-proxy interface in the downward direction. After configuring this command, the interface becomes the one connected with the mroute-proxy in the upward direction, and associates with and maintains the group information from the interfaces in the downward direction. Use the **no** or **default** form of this command to disable the default setting.

**ipv6 mld proxy-service**

**no ipv6 mld proxy-service**

**default ipv6 mld proxy-service**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Interface configuration mode

**Usage Guide** The configurable max-number limit is 32. The number of the interfaces with MLD Proxy enabled is limited by the number multicast interfaces supported device. After receiving the query packet, the proxy-service interface replies according to the member information, which are collected from the mroute-proxy interface and maintained by the proxy-service interface itself. With proxy-service configured, this interface owns the host action rather than the router action.

The **ipv6 mld mroute-proxy interface** command configuration on the associated interface in the downward direction is removed automatically if the switchport operation is performed on the interfaces.

**Configuration** The following example sets the interface proxy-service.

**Examples** Ruijie(config-if)# ipv6 mld proxy-service

| Related<br>Commands | Command | Description |

## 4.11 ipv6 mld querier-timeout

Use this command to set the querier alive period. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld querier-timeout** *seconds*

**no ipv6 mld querier-timeout**

**default ipv6 mld querier-timeout**

| Parameter<br>Description | Parameter      | Description                                                                   |
|--------------------------|----------------|-------------------------------------------------------------------------------|
|                          | <i>seconds</i> | The querier alive period, in the range from 60 to 300 in the unit of seconds. |

**Defaults** The default is 255 seconds.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** After the querier sends the query packet, the querier will wait to receive the query packet sent by another querier within the alive period. If no packet is received by the first querier within the alive period, then the first querier takes itself as the only querier on the network segment.

**Configuration** The following example sets the querier alive period to 200 seconds.

**Examples** Ruijie(config-if-Ethernet 0/1)# ipv6 mld querier-timeout 200

**Related  
Commands**

## 4.12 ipv6 mld query-interval

Use this command to set the query interval for the general member. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld query-interval** *seconds*

**no ipv6 mld query-interval**

**default ipv6 mld query-interval**

**Parameter  
Description**

| Parameter      | Description                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------|
| <i>seconds</i> | The query interval for the general member, in the range from 1 to 18000 in the unit of seconds. |

**Defaults** The default is 125 seconds.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** The interval of the timer for sending the general query packets can be changed by configuring the query-interval for the general member.

**Configuration** The following example sets the query-interval for the general member on the interface Ethernet 0.

**Examples** Ruijie(config-if)# **ipv6 mld query-interval 120**

The following example sets the query-interval for the general member to the default value on the interface Ethernet 0.

Ruijie(config-if)# **no ipv6 mld query-interval**

| Related<br>Commands | Command | Description |

**Description**

## 4.13 ipv6 mld query-max-response-time

Use this command to set the maximum response time.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld query-max-response-time** *seconds*

**no ipv6 mld query-max-response-time**

**default ipv6 mld query-max-response-time**

| Parameter<br>Description | Parameter | Description                                                                 |
|--------------------------|-----------|-----------------------------------------------------------------------------|
|                          | seconds   | The maximum response time, in the range from 1 to 25 in the unit of seconds |

**Defaults** The default is 10 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to control the maximum response time of the host after the device sends the query packets. If there is no response within the maximum response time, MLD will remove the corresponding group from the group member list.

**Configuration Examples** The following example sets the maximum query response time on the interface gigabitEthernet 0/1.

```
Ruijie(config-if)# ipv6 mld query-max-response-time 20
```

The following example sets the maximum query response time on the interface gigabitEthernet 0/1.

```
Ruijie(config-if)# no ipv6 mld query-max-response-time
```

| Related<br>Commands | Command | Description |

## 4.14 ipv6 mld robustness-variable

Use this command to set querier robustness value. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld robustness-variable** *number*

**no ipv6 mld robustness-variable**

**default ipv6 mld robustness-variable**

### Parameter Description

| Parameter | Description                                                  |
|-----------|--------------------------------------------------------------|
| number    | Sets the querier robustness value, in the range from 2 to 7. |

### Defaults

The default is 2.

### Command Mode

Interface configuration mode

### Usage Guide

N/A

### Configuration

The following example sets the querier robustness value to 3.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0
Ruijie(config-if)# ipv6 mld robustness-variable 3
```

### Description

## 4.15 ipv6 mld ssm-map enable

Use this command to enable the mld ssm-map function.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld ssm-map enable**

**no ipv6 mld ssm-map enable**

**default ipv6 mld ssm-map enable**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** With this command configured, the group information dynamically learned will be added to the related source record forcibly. Usually, this command is set with the **ipv6 mld ssm-map static** command.

**Configuration** The following example enables the mld ssm-map function in the global configuration mode.

**Examples** Ruijie(config)# ipv6 mld ssm-map enable

| Related Commands | Command | Description |

## 4.16 ipv6 mld ssm-map static

Use this command to set the mld ssm-map static mapping source record in the global configuration mode.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld ssm-map static** *access-list X:X:X:X::X*

**no ipv6 mld ssm-map static** *access-list X:X:X:X::X*

**default ipv6 mld ssm-map static** *access-list source-address*

| Parameter Description | Parameter   | Description                                            |
|-----------------------|-------------|--------------------------------------------------------|
|                       | access-list | Sets the IPv6 ACL name.                                |
|                       | X:X:X:X::X  | Sets the unicast address for the group record mapping. |

**Defaults** There is no mapping source address by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used with the **ipv6 mld ssm-map enable** command. With this command configured, the received mldv1 packets are mapped to the correspondent source record.

**Configuration** The following example maps all group record of the ACL name to the source address 4444::1234.

**Examples** Ruijie(config)# ipv6 mld ssm-map static te 4444::1234

| Related<br>Commands | Command | Description |

**Description**

## 4.17 ipv6 mld static-group

Use this command to add an interface to a group statically. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld static-group** *group-address*

**no ipv6 mld static-group** *group-address*

**default ipv6 mld static-group** *group-address*

| Parameter<br>Description | Parameter     | Description                                           |
|--------------------------|---------------|-------------------------------------------------------|
|                          | group-address | Sets the IPv6 non-management multicast group address. |

**Defaults** The interface is not added to any group statically.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** Use this command to add a multicast group to the interface directly. The difference from the join-group is that the packet interaction is not necessary.

Use this command when it is necessary to add a group member to the interface. It is worth mentioning that only the **no ipv6 mld static-group** command can be used to delete the group, but not the **clear** command.

**Configuration** The following example adds interface Eth0/1 to group ff55::3 statically.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface fast 0/1
Ruijie(config-if)# ipv6 mld static-group ff55::3
```

**Description**

## 4.18 ipv6 mld version

Use this command to set the MLD version number on the interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld version** { 1 | 2 }

**no ipv6 mld version**

**default ipv6 mld version**

### Parameter Description

| Parameter | Description                  |
|-----------|------------------------------|
| { 1   2 } | Sets the MLD version number. |

### Defaults

The default is 2.

### Command Mode

Interface configuration mode

### Usage Guide

Use this command to control the MLD version number.

### Configuration

The following example sets the MLD version 1.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ipv6 mld version 1
```

### Description

## 4.19 show ipv6 mld groups

Use this command to display the group connected with the switch and the group information learned from the MLD.

**show ipv6 mld groups** [ *group-address* | *interface-type interface-number* ] [ **detail** ]

### Parameter Description

| Parameter        | Description                                        |
|------------------|----------------------------------------------------|
| group-address    | Sets the IPv6 multicast group address in 128 bits. |
| interface-type   | Sets the interface type.                           |
| interface-number | Sets the interface number.                         |

|               |                                     |
|---------------|-------------------------------------|
| <b>detail</b> | Displays the information in detail. |
|               | Displays all the group information. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode /Interface configuration mode

**Usage Guide** Use this command without the parameters to display the information including the group address, the interface type and the multicast group information. Use this command with a parameter to display the information on a specific group.

**Configuration** The following example displays all group information.

**Examples**

```
Ruijie# show ipv6 mld groups
MLD Connected Group Membership
Group Address Interface Uptime Expires Last Reporter
ff66::1 VLAN1 00:10:57 00:02:16 fe80::2d0:f8ff:fe22:3378
```

The following example displays the detailed information.

```
Ruijie# show ipv6 mld groups detail
Interface:      VLAN 1
Group:          ff66::1
Uptime:         00:10:26
Group mode:     Exclude (Expires: 00:02:47)
Last reporter:  fe80::2d0:f8ff:fe22:3378
Source list is empty
```

**Description**

## 4.20 show ipv6 mld interface

Use this command to display the configurations on the interface.

**show ipv6 mld interface** [ *interface-type interface-number* ]

| <b>Parameter Description</b> | Parameter        | Description                |
|------------------------------|------------------|----------------------------|
|                              | interface-type   | Sets the interface type.   |
|                              | interface-number | Sets the interface number. |

**Defaults** N/A

**Command Mode** User EXEC mode / Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the state information of all interfaces.

**Examples**

```
Ruijie# show ipv6 mld interface
Interface VLAN 2 (Index 4098)
  MLD Enabled, Inactive, Version 2 (default)
  MLD interface limit is 1024
  MLD interface has 0 group-record states
  MLD interface has 1 join-group records
  MLD interface has 0 static-group records
  MLD activity: 0 joins, 0 leaves
  MLD query interval is 125 seconds
  MLD querier timeout is 255 seconds
  MLD max query response time is 10 seconds
  Last member query response interval is 10 (1/10s)
  Last member query count is 2
  Group Membership interval is 260
  Robustness Variable is 2
```

## 4.21 show ipv6 mld ssm-mapping

Use this command to display the mapping information of the source address for the group record.

**show ipv6 mld ssm-mapping** [ *group-address* ]

**Parameter Description**

| Parameter     | Description                 |
|---------------|-----------------------------|
| group-address | Displays the group address. |

**Defaults** N/A

**Command Mode** User EXEC mode / Privileged EXEC mode

**Usage Guide**    N/A

**Configuration**    The following example displays the state information of all interfaces.

**Examples**

```
Ruijie# show ipv6 mld interface
Interface VLAN 2 (Index 4098)
  MLD Enabled, Inactive, Version 2 (default)
  MLD interface limit is 1024
  MLD interface has 0 group-record states
  MLD interface has 1 join-group records
  MLD interface has 0 static-group records
  MLD activity: 0 joins, 0 leaves
  MLD query interval is 125 seconds
  MLD querier timeout is 255 seconds
  MLD max query response time is 10 seconds
  Last member query response interval is 10 (1/10s)
  Last member query count is 2
  Group Membership interval is 260
  Robustness Variable is 2
```

## 5 PIM-DM Commands

### 5.1 clear ip pim dense-mode track

Use this command to clear the statistics of PIM-DM packets.

**clear ip pim dense-mode track**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to reconfigure the start time of the statistics and clear the PIM packet counter.

**Configuration** The following example clears the statistics of PIM-DM packets.

**Examples** Ruijie# clear ip pim dense-mode track

| Related<br>Commands | Command                      | Description                                 |
|---------------------|------------------------------|---------------------------------------------|
|                     | show ip pim dense-mode track | Displays the statistics of the PIM packets. |

**Platform Description** N/A

### 5.2 ip pim dense-mode

Use this command to enable PIM-DM on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim dense-mode**

**no ip pim dense-mode**

**default ip pim dense-mode**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode  
**Mode**

**Usage Guide**

- ✔ Before enabling the PIM-DM, enable the multicast forwarding function in the global configuration mode. Otherwise, the multicast data packet cannot be forwarded even the PIM-DM is enabled.
- ✔ Once the PIM-DM is enabled, the IGMP is enabled automatically on the interface without manual configuration.
- ✔ During the execution of this command, if the prompt "Failed to enable PIM-DM on <Interface Name>, resource temporarily unavailable, please try again" appears, re-execute this command.
- ✔ During the execution of this command, if the prompt "PIM-DM Configure failed! VIF limit exceeded in NSM!!!" appears, it indicates the allowed configured multicast interface number exceeds the upper limit of the multicast interfaces. In this case, if it's still necessary to enable the PIM-DM on the interface, delete the unnecessary PIM-DM, PIM-SM or DVMRP interfaces.
- ✔ It is not recommended to configure different multicast routing protocols on different interfaces of a device.

**Configuration** The following example enables PIM-DM on the interface.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim dense-mode
```

**Related Commands**

| Command | Description |
|---------|-------------|

**Platform** N/A  
**Description**

## 5.3 ip pim neighbor-filter

Use this command to enable the neighbor filtering on the interface. If the neighbor filtering is set, PIM-DM will not establish the peering relationship with this neighbor or will terminate the established peering relationship with this neighbor once the neighbor is denied by the filtering access list. Use the **no** or **default** form of this command is to restore the default setting.

**ip pim neighbor-filter** *access-list*  
**no ip pim neighbor-filter** *access-list*  
**default ip pim neighbor-filter** *access-list*

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <i>access-list</i> | Access control list supporting numerical ACL in the range from 1 to 99 and name ACL |
|--------------------|-------------------------------------------------------------------------------------|

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example enables the neighbor filtering on the interface.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim neighbor-filter 14
```

- ✓ 1. When the associated ACL rule is permit, only the neighbor address in ACL can be used as the PIM neighbor of the current interface. When the associated ACL rule is deny, the neighbor address in ACL cannot be used as the PIM neighbor of the current interface.
- ✓ 2. Peering relationship refers to the interaction of protocol packets between the PIM neighbors. If the peering relationship with a PIM device is terminated, the neighbor relationship with this device will not be established, and the PIM protocol packets from this device will not be received.

## 5.4 ip pim override-interval

Use this command to reconfigure the override-interval of the hello message.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim override-interval** *interval-milliseconds*

**no ip pim override-interval**

**default ip pim override-interval**

**Parameter Description**

| Parameter                    | Description                                               |
|------------------------------|-----------------------------------------------------------|
| <i>interval-milliseconds</i> | In the range from 1 to 65,535 in the unit of milliseconds |

**Defaults** The default is 2,500 milliseconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Configuring the override-interval is to set the pruning veto time for the interface.

**Configuration** The following example sets the override-interval to 300 milliseconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim override-interval 3000
```

**Description**

## 5.5 ip pim propagation-delay

Use this command to reconfigure the propagation-interval of the hello message.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim propagation-delay** *interval-milliseconds*

**no ip pim propagation-delay**

**default ip pim propagation-delay**

**Parameter  
Description**

| Parameter                    | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <i>interval-milliseconds</i> | Propagation-interval of the hello message in the range from 1 to 32,767 in the unit of milliseconds |

**Defaults** The default is 500 milliseconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Configuring the propagation-delay is to set the transmission delay time for the interface.

**Configuration** The following example sets the propagation-delay to 600 milliseconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim propagation-delay 600
```

Description

## 5.6 ip pim query-interval

Use this command to reconfigure the interval of sending the hello message.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim query-interval** *interval-seconds*

**no ip pim query-interval**

**default ip pim query-interval**

| Parameter<br>Description | Parameter               | Description                                                                                |
|--------------------------|-------------------------|--------------------------------------------------------------------------------------------|
|                          | <i>Interval-seconds</i> | Interval of sending the hello message in the range from 1 to 65,535 in the unit of seconds |

Defaults The default is 30 milliseconds.

Command Interface configuration mode  
Mode

Usage Guide If hello interval is set, the hello holdtime value will be updated to 3.5 times of hello interval.

Configuration The following example sets the interval of sending the hello message to 123 seconds.

Examples

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim query-interval 123
```

| Related<br>Commands | Command | Description |

|                     | N/A     | N/A         |

Platform N/A

Description

## 5.7 ip pim state-refresh disable

Use this command to prohibit the interface from processing and forwarding the PIM-DM state refresh messages.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim state-refresh disable**  
**no ip pim state-refresh disable**  
**default ip pim state-refresh disable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** By default, the PIM-DM state refresh messages can be processed and forwarded.

**Command  
Mode** Global configuration mode

**Usage Guide** When the state refresh function is disabled, the PIM-DM state refresh message is not processed and forwarded. The sent Hello message does not contain the status refresh option. Consequently, the SR Cap field will not be processed when the Hello message is received.

**Configuration** The following example disables the processing of the PIM-DM state refresh message.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim state-refresh disable
```

Generally, it is not recommended to disable the status refresh function because disabling this function may converge the PIM-DM multicast forwarding tree again that has been converged, resulting in unnecessary waste of bandwidth and oscillation of multicast routing table.

|---------|-------------|
| N/A     | N/A         |

**Platform  
Description** N/A

## 5.8 ip pim state-refresh origination-interval

Use this command to set the interval of sending the PIM-DM state refresh message. The interval is the seconds elapsed between two state refresh messages.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim state-refresh origination-interval** *interval-seconds*  
**no ip pim state-refresh origination-interval**  
**default ip pim state-refresh origination-interval**

**Parameter  
Description**

| Parameter               | Description                                                       |
|-------------------------|-------------------------------------------------------------------|
| <i>Interval-seconds</i> | Interval of sending the PIM-DM update message in the range from 1 |

|  |                           |
|--|---------------------------|
|  | to 100 in unit of seconds |
|--|---------------------------|

**Defaults** The default is 60 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the interval of sending the PIM-DM state refresh message to 65 seconds.

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim state-refresh
origination-interval 65
```

## 5.9 ip pim mib dense-mode

Use this command to switch the device from the PIM MIB sparse mode to the PIM MIB dense mode.

Use the **no** form or **default** form of this command to switch back to the PIM MIB sparse mode.

**ip pim mib dense-mode**

**no ip pim mib dense-mode**

**default ip pim mib dense-mode**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The device is in the PIM MIB sparse mode by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example switches the device from the PIM MIB sparse mode to the PIM MIB dense mode.

```
Ruijie# configure terminal
```

```
Ruijie(config)# ip pim mib dense-mode
```

## 5.12 show ip pim dense-mode neighbor

Use this command to display the information about the PIM-DM neighbors.

**show ip pim dense-mode neighbor** [ *interface-type interface-number* ]

| Parameter   | Parameter                                        | Description                     |
|-------------|--------------------------------------------------|---------------------------------|
| Description | <i>interface-type</i><br><i>interface-number</i> | Interface type and interface ID |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the information about the PIM-DM neighbors.

### Examples

```
Ruijie# show ip pim dense-mode neighbor
Neighbor-Address Interface      Uptime/Expires      Ver
10.10.10.1      FastEthernet 0/45  00:19:29/00:01:21  v2
50.50.50.1      VLAN 4          00:22:09/00:01:39  v2
```

Description of fields in the results:

| Field            | Description                                   |
|------------------|-----------------------------------------------|
| Neighbor-Address | IP address of the neighbor                    |
| Interface        | Name of the interface connecting the neighbor |
| Uptime/Expires   | Valid time and aging time of the entry        |

**Description**

## 5.13 show ip pim dense-mode nexthop

Use this command to display the information about the PIM-DM next hop.

**show ip pim dense-mode nexthop****Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode**Usage Guide** N/A**Configuration** The following example displays the information about the PIM-Dm next hop:**Examples**

```
Ruijie# show ip pim dense-mode nexthop
Destination  Nexthop  Nexthop  Nexthop  Metric Pref
              Num      Addr      Interface
1.1.1.111    1        50.50.50.1 VLAN 4    0      1
```

| Field             | Description                             |
|-------------------|-----------------------------------------|
| Destination       | Multicast source IP address             |
| Nexthop Num       | Number of next hop                      |
| Nexthop Addr      | IP address of next hop                  |
| Nexthop interface | Interface connecting to the of next hop |
| Metric            | Route metric                            |
| Pref              | Route priority                          |

## 5.14 show ip pim dense-mode track

Use this command to display the statistics of the PIM-DM packets.

**show ip pim dense-mode track****Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command is used to display the number of sent and received PIM packets during the period from the beginning of the statistics till now. When the system starts up, it sets the start time of the statistics. The start time of the statistics is reconfigured and the PIM packet counter is cleared on calling the clear ip pim dense-mode track every time.

**Configuration** The following example displays the statistics of the PIM-DM packets.

**Examples**

```
Ruijie# show ip pim dense-mode track
          PIM packet counters
Elapsed time since counters cleared: 00:04:03

          received      sent
Valid PIMDM packets:      1          8
Hello:                    1          8
Join/Prune:                0          0
Graft:                     0          0
Graft-Ack:                 0          0
Assert:                    0          0
State-Refresh:             0          0
PIM-SM-Register:          0          0
PIM-SM-Register-Stop:     0          0
PIM-SM-BSM:                0          0
PIM-SM-C-RP-ADV:          0          0
Unknown Type:              0
Errors:
Malformed packets:        0
Bad checksums:            0
Unknown PIM version:      0
Send errors:                0
```

**Related  
Commands**

## 6 PIM-SM Commands

### 6.1 clear ip pim sparse-mode bsr rp-set

Use this command to clear all the RP information learnt dynamically.

**clear ip pim sparse-mode bsr rp-set \***

| Parameter<br>Description | Parameter | Description        |
|--------------------------|-----------|--------------------|
|                          | *         | Clears all RP-SET. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** All the RP information learnt dynamically can be cleared manually.

**Configuration** The following example clears all the RP information learnt dynamically.

**Examples** Ruijie# clear ip pim sparse-mode bsr rp-set \*

| Related<br>Commands | Command | Description |

|                     | N/A     | N/A         |

**Platform Description** N/A

### 6.2 clear ip pim sparse-mode track

Use this command to reconfigure the start time of the statistics and clear the PIMv6 packet counter.

**clear ip pim sparse-mode track**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to reconfigure the start time of the statistics and clear the PIM packet counter.

**Configuration** The following example clears the PIM packet counter.

**Examples**

```
Ruijie# clear ip pim sparse-mode track
```

**Related  
Commands**

| <b>show ip pim sparse-mode track</b> | Displays the PIM packet statistics. |

**Platform** N/A

**Description**

## 6.3 ip pim accept-bsr list

Use this command to confine the BSR address range.

Use the **no** or **default** form this command to restore the default setting.

**ip pim accept-bsr list** *access-list*

**no ip pim accept-bsr**

**default ip pim accept-bsr**

**Parameter  
Description**

| Parameter                      | Description            |
|--------------------------------|------------------------|
| <b>list</b> <i>access-list</i> | IP standard number ACL |

**Defaults** By default, the PIMSM router receives all external BSM packets.

**Command  
Mode** Global configuration mode

**Usage Guide** Use this command to limit the range of the legal BSR.

**Configuration** The following example confines the BSR address range.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim accept-bsr list 1
```

**Platform** N/A

**Description**

## 6.4 ip pim accept-crp list

Use this command to confine the C-RP address range and the multicast group address range it serves.

Use the **no** or **default** form of this command to restore the default setting,

**ip pim accept-crp list** *access-list*

**no ip pim accept-crp**

**default ip pim accept-crp**

### Parameter Description

| Parameter                      | Description             |
|--------------------------------|-------------------------|
| <b>list</b> <i>access-list</i> | IP extension number ACL |

### Defaults

By default, the elected BSR receives all external advertisements of candidate RPs.

### Command Mode

Global configuration mode

### Usage Guide

With this command configured on the candidate BSR, when this BSR becomes the elected BSR, it is able to limit the address range of the legal C-RP and the multicast group range it serves.

### Configuration Examples

The following example confines the C-RP address range and the multicast group address range it serves.

```
Ruijie (config)# configure terminal
Ruijie (config)# ip pim accept-crp list 100
```

### Related Commands

## 6.5 ip pim accept-crp-with-null-group

Use this command to receive the C-RP-ADV packets whose prefix-count is 0.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim accept-crp-with-null-group**

**no ip pim accept-crp-with-null-group**

**default ip pim accept-crp-with-null-group**

### Parameter

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                    |     |     |
|--------------------|-----|-----|
| <b>Description</b> |     |     |
|                    | N/A | N/A |

**Defaults** By default, the BSR does not receive the C-RP-ADV packets whose prefix-count is 0.

**Command Mode** Global configuration mode

**Usage Guide** With this command configured on the candidate BSR, when this BSR becomes the elected BSR, it is able to receive the C-RP-ADV packets whose prefix-count is 0, and considers this C-RP supports all groups.

**Configuration** The following example receives the C-RP-ADV packets whose prefix-count is 0.

**Examples**

```
Ruijie (config)# configure terminal
Ruijie (config)# ip pim accept-crp-with-null-group
```

| <b>Related Commands</b> | Command | Description |

**Description**

## 6.6 ip pim accept-register list

Use this command to confine the address range of the (S,G) entry of the register packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim accept-register** { **list** *access-list* [**route-map** *map-name* ] | **route-map** *map-name* [**list** *access-list* ] }

**no ip pim accept-register**

**default ip pim accept-register**

| <b>Parameter Description</b> | Parameter                        | Description                                                                                                                                                                |
|------------------------------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <b>list</b> <i>access-list</i>   | Uses an extended IP access list to define the (S, G) address range. Access control list supporting numerical ACL in the range of 100 to 199 and 2000 to 2699 and name ACL. |
|                              | <b>route-map</b> <i>map-name</i> | Uses a route map to define the (S, G) address range.                                                                                                                       |

**Defaults** The (S, G) address range is not confined by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to confine the source IP address of register messages on RP.

**Configuration** The following example confines the source address of register packets on the RP.

**Examples**

```
Ruijie (config)# ip pim accept-register list 100
Ruijie (config)# access-list 100 permit ip 192.168.195.0 0.0.0.255 225.1.1.1
0.0.0.255
```

| <b>access-list</b> | N/A         |

**Platform** N/A

**Description**

## 6.7 ip pim bsr-border

Use this command to configure the BSR border.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim bsr-border**

**no ip pim bsr-border**

**default ip pim bsr-border**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** No BSR border is configured by default.

**Command  
Mode** Interface configuration mode

**Usage Guide** To restrain BSM flooding, configure BSR border on the interface so that the interface drops BSM packets upon receiving them and the BSM packets are not forwarded from this interface.

**Configuration** The following example sets the BSR border on the interface *g 0/3*

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ip pim bsr-border
```

**Description**

## 6.8 ip pim bsr-candidate

Use this command to configure the C-BSR.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim bsr-candidate** *interface-type interface-number* [ *hash-mask-length* [ *priority-value* ] ]

**no ip pim bsr-candidate**

**default ip pim bsr-candidate**

**Parameter  
Description**

| Parameter                                        | Description                                                                                              |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | Interface type and number                                                                                |
| <i>hash-mask-length</i>                          | (Optional) HASK mask length configured for electing the RP in the range from 0 to 32, The default is 10. |
| <i>priority-value</i>                            | (Optional) Priority configured for the candidate BSR in the range from 0 to 255. The default is 64.      |

**Defaults** No C-BSR is configured by default.

**Command  
Mode** Global configuration mode

**Usage Guide** A PIM-SM domain must contain a unique BootStrap Router (BSR). BSR is responsible for collect and issue RP information. A unique recognized BSR is elected among multiple candidate BSRs through the bootstrap packet. Before BSR information is available, C-BSRs consider them to be the BSR, and regularly send bootstrap packets using the multicast address 224.0.0.13 in the PIM-SM domain. This packet contains the address and priority of the BSR.

This command allows the device to send a bootstrap message to all the PIM neighbors using the assigned BSR address. Each neighbor compares the original BSR address with the address in the received bootstrap message. If the IP address of the received address is equal to or larger than the original address, each neighbor saves this received address as the BSR address. Otherwise, they will discard this message.

The current device considers itself to be BSR until it receives a bootstrap message from another candidate BSR and is notified that it has a higher priority value (or the same priority value, but with a larger IP address).

**Configuration** The following example configures the C-BSR.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim bsr-candidate g 0/3 30 192
```

**Description**

## 6.9 ip pim dr-priority

Use this command to set the DR priority.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim dr-priority** *priority-value*

**no ip pim dr-priority**

**default ip pim dr-priority**

| Parameter<br>Description | Parameter             | Description                                                                             |
|--------------------------|-----------------------|-----------------------------------------------------------------------------------------|
|                          | <i>priority-value</i> | The larger the value, the higher the priority is. The range is from 0 to 4,294,967,294. |

**Defaults** The default is 1.

**Command Mode** Interface configuration mode

**Usage Guide** To select a DR:

If the priority parameter of the Hello message is set for the devices in a LAN, the one of the highest priority is elected to be the DR. If several devices have the same priority, the one of the largest IP address is elected to be the DR.

If the priority parameter of the Hello message is not set for the devices in a LAN, the one of the largest IP address is elected to be the DR.

**Configuration** The following example sets the DR priority.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ip pim dr-priority 10000
```

## 6.11 ip pim jp-timer

Use this command to set the interval to send the join/prune message.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim jp-timer** *seconds*

**no ip pim jp-timer**

**default ip pim jp-timer**

### Parameter Description

| Parameter      | Description                                                                                 |
|----------------|---------------------------------------------------------------------------------------------|
| <i>seconds</i> | Interval to send the join/prune message in the range from 1 to 65535 in the unit of seconds |

**Defaults** The default is 60 seconds.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to set the interval to send the Join/Prune message.

**Configuration Examples** The following example sets the interval to send the Join/Prune message to 50 seconds.

```
Ruijie# configure terminal
Ruijie(config)# ip pim jp-timer 50
```

## 6.12 ip pim neighbor-filter

Use this command to confine the neighbor address range.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim neighbor-filter** *access\_list*

**no ip pim neighbor-filter** *access\_list*

**default ip pim neighbor-filter** *access\_list*

**Parameter Description**

| Parameter          | Description                                                                    |
|--------------------|--------------------------------------------------------------------------------|
| <i>access_list</i> | Access control list supporting numerical ACL in the range 1 to 99 and name ACL |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Neighbor filtering can enhance the security of a PIM-enabled network and provide neighbor restriction. As long as a neighbor is denied by the access list, PIM-SM will not establish the peering relationship with this neighbor or terminate the established peering relationship with this neighbor.

**Configuration Examples** The following example blocks the neighbor address 192.168.1.5..

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
```

```
Ruijie(config-if)# ip pim neighbor-filter 14
Ruijie(config-if)# exit
Ruijie(config)# access-list 14 deny 192.168.1.5 0.0.0.255
```

**Related

## 6.13 ip pim neighbor-tracking

Use this command to disable join restraint on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim neighbor-tracking**

**no ip pim neighbor-tracking**

**default ip pim neighbor-tracking**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

This function is enabled by default.

**Command  
Mode**

Interface configuration mode

**Usage Guide**

Use this command to disable join restraint on the interface. With join constraint enabled, the interface is constrained not to send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. On the other hand, with join constrain disabled, the interface will send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. This function allows upstream routers to track how many receivers in downstream in accord with all received Join messages.

**Configuration**

The following example disables join restraint on the interface.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ip pim neighbor-tracking
```

**Related  
Commands**

Description

## 6.14 ip pim override-interval

Use this command to set the override-interval on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim override-interval** *milliseconds*

**no ip pim override-interval**

**default ip pim override-interval**

Parameter  
Description

| Parameter                    | Description                                              |
|------------------------------|----------------------------------------------------------|
| <i>interval-milliseconds</i> | In the range from 1 to 65535 in the unit of milliseconds |

Defaults The default is 2500 milliseconds.

Command  
Mode Interface configuration mode

Usage Guide Use this command to set the override-interval for the interface.

 Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

Configuration The following example sets the override-interval as 3000 milliseconds.

Examples

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config)# ip pim override-interval 3000
```

| Parameter               | Description                          |
|-------------------------|--------------------------------------|
| <i>interval-seconds</i> | In the range from 1 to 65535 seconds |

**Defaults**

The default is 5 seconds.

**Command  
Mode**

Global configuration mode

**Usage Guide**

Use this command to set the registration probe time. The DR can send the null registration message to the RP in a period before the registration suppression time expires. This period is called probe time of null registration packet.

The probe time must be less than half of registration suppression time. Furthermore, 3\* registration suppression time plus registration probe time should be no more than 65535s or otherwise the system triggers an alarm.

**Configuration**

The following example sets the probe time to 6 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim probe-interval 6
```

**Related

**Description**

## 6.16 ip pim propagation-delay

Use this command to set the propagation-delay on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim propagation-delay** *milliseconds*

**no ip pim propagation-delay**

**default ip pim propagation-delay**

**Parameter  
Description**

| Parameter                    | Description                               |
|------------------------------|-------------------------------------------|
| <i>interval-milliseconds</i> | In the range from 1 to 32765 milliseconds |

**Defaults** The default is 500 milliseconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to set the propagation-delay for the interface.

Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

**Configuration** The following example sets the propagation delay to 600 milliseconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config)# ip pim propagation-delay 600
```

**Related Commands**

**Description**

## 6.17 ip pim query-interval

Use this command to set the interval to send the hello packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim query-interval** *seconds*

**no ip pim query-interval**

**default ip pim query-interval**

**Parameter Description**

| Parameter               | Description                                                                              |
|-------------------------|------------------------------------------------------------------------------------------|
| <i>interval-seconds</i> | Interval to send the Hello message, in the range from 1 to 65535 in the unit of seconds. |

**Defaults** The default is 30 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** Upon updating the interval to send the Hello message, the time of holding the Hello message is updated by the following principle: The hold time is updated to be 3.5 times the transmission interval.

If the transmission interval\*3.5 is more than 65535, the hold time is updated to 18752.

**Configuration** The following example sets the interval to send the hello packets to 123 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config)# ip pim query-interval 123
```

**Description**

## 6.18 ip pim register-decapsulate-forward

Use this command to enable the RP to decapsulate the register packets and forward the multicast packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-decapsulate-forward**

**no ip pim register-decapsulate-forward**

**default ip pim register-decapsulate-forward**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command  
Mode** Global configuration mode

**Usage Guide** Use this command to implement the decapsulate of the pim sm registration packets with the multicast data packets received on the candidate RP and forward the multicast data packets.

As the decapsulate and forward are performed by the software, it is not recommended to configure this command in the case that many registration packets need to be decapsulated and forwarded, which may cause the CPU busy with this function configured.

**Configuration  
Examples** The following example enables the RP to decapsulate the register packets and forwards the multicast packets.

```
Ruijie# configure terminal
Ruijie(config)# ip pim register-decapsulate-forward
```

## 6.19 ip pim register-checksum-wholepkt

Use this command to calculate the checksum of the whole register packet.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-checksum-wholepkt** [ **group-list** *access-list* ]

**no ip pim register-checksum-wholepkt** [ **group-list** *access-list* ]

**default ip pim register-checksum-wholepkt** [ **group-list** *access-list* ]

| Parameter Description | Parameter          | Description                                                                                                                                                                                                   |
|-----------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>access-list</i> | Access-list: access control list supporting numerical ACL in the range from 100 to 199 and from 1300 to 1999 and name ACL.<br>Group-list access-list :all multicast packets use this configuration by default |

**Defaults** By default, the checksum of register messages calculates the head of PIM message and register message rather than the whole PIM message

**Command Mode** Global configuration mode

**Usage Guide** Some vendors calculate checksum based on the overall registration packets. Ruijie Networks introduces this function for the compatibility with devices of other vendors.

**Configuration Examples** The following example calculates the checksum of the whole register packet..

```
Ruijie# configure terminal
Ruijie(config)# ip pim register-checksum-wholepkt group-list 99
Ruijie(config)# access-list 99 permit 225.1.1.1 0.0.0.255
```

## 6.20 ip pim register-rate-limit

Use this command to limit the rate of register packets. Use the **no** form of this command to restore the default setting.

**ip pim register-rate-limit** *rate*

**no ip pim register-rate-limit**

**default ip pim register-rate-limit**

| Parameter<br>Description | Parameter   | Description                                                                                  |
|--------------------------|-------------|----------------------------------------------------------------------------------------------|
|                          | <i>rate</i> | Maximum number of register packets that can be sent per second, in the range from 1 to 65535 |

**Defaults** By default, there is no rate limitation on register messages.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure speed of transmitting register packet in each (S, G) status, not the speed of transmitting register packets in the system. Using this command will decrease the load of source DR and RP. The register packets can be transmitted at the speed within the limit.

**Configuration** The following example limits the rate of register packets.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim register-rate-limit 3000
```

## 6.22 ip pim register-source

Use this command to specify the source IP address of the register packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-source** { *local\_address* | *interface-type interface-number* }

**no ip pim register-source**

**default ip pim register-source**

| <b>Parameter Description</b> | Parameter                                                                                                                    | Description                                                                     |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
|                              | <i>interface-type</i>                                                                                                        | Interface whose IP address is used as the source IP address of register packets |
|                              | <i>interface-number</i>                                                                                                      |                                                                                 |
|                              | <i>local_address</i>                                                                                                         | Specifies the source IP address of the register packet.                         |
| <b>Defaults</b>              | By default, the source IP address of register packets is the IP address of the DR interface connecting the multicast source. |                                                                                 |
| <b>Command Mode</b>          | Global configuration mode                                                                                                    |                                                                                 |
| <b>Usage Guide</b>           | This command is used to configure the source IP address of register messages.                                                |                                                                                 |

The source IP address must be reachable. When RP receives the register packet, it transmits Register-Stop packet, using its source IP address as the destination IP address of the Register-Stop packet.

It is not necessary to enable the PIM.

**Configuration** The following example specifies the source IP address of the register packets.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim register-source 192.168.195.80
Ruijie(config)# ip pim register-source g 0/3
```

## 6.23 ip pim register-suppression

Use this command to set the register suppression time.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-suppression** *seconds*

**no ip pim register-suppression**

**default ip pim register-suppression**

**Parameter  
Description**

| Parameter          | Description                                                           |
|--------------------|-----------------------------------------------------------------------|
| <i>suppression</i> | Suppression time in the range from 1 to 65535 in the unit of seconds. |

**Defaults** The default is 60 seconds.

**Command  
Mode** Global configuration mode

**Usage Guide** Executing this command on the DR will change the register packet suppression time configured. if the **ip pim rp-register-kat** command is not configured, executing this command on RP will modify the period of RP keepalive.

**Configuration** The following example sets the register suppression time to 100 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim register-suppression 100
```

## 6.24 ip pim rp-address

Use this command to configure the static RP.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim rp-address** *rp-address* [ *access\_list* ]

**no ip pim rp-address** *rp-address* [ *access\_list* ]

**default ip pim rp-address** *rp-address* [ *access\_list* ]

| <b>Parameter Description</b> | Parameter          | Description                                                                                                                                     |
|------------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <i>rp-address</i>  | IP address of RP                                                                                                                                |
|                              | <i>access_list</i> | Access control list supporting numerical ACL in the range 1 to 99 and 1300 to 1999 and name ACL. All multicast groups are supported by default. |

**Defaults** No IP address is configured for the static RP by default.

**Command Mode** Global configuration mode

**Usage Guide** This system supports the configuration of multicast static RP, as well as the configuration of static RP and BSR mechanisms at the same time. When you use this command, note that:

If both the BSR mechanism and the static RP configuration take effect, the dynamic configuration takes precedence.

You can configure multiple multicast groups (using ACL) or all multicast groups (not using ACL) for the static RP. But a static RP can be configured only once.

If there are more than one static RP in a multicast group, the one of the highest IP address is used.

Only the addresses permitted by ACL are valid multicast groups. By default, all the multicast groups 224/4 are permitted.

After configuration is performed, the static RP's source IP address is inserted to the group range-based static RP group tree structure. Each group range-based static multicast group maintains the chain list structure of a static RP group. This chain list is sorted in descending order of IP address. When you select a RP from a static RP group, the first entry, namely the one with the largest IP address, will be selected first.

Deleting a static IP address also deletes this address from all the existing static RP groups and selects one from in the existing RP group tree structure as the RP address.

**Configuration** The following example specifies the source IPv6 address of the register packet..

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim rp-address 210.34.0.55 4
Ruijie(config)# access-list 4 permit 255.1.1.1 0.0.0.255
```

| <i>priority-value</i>                            | (Optional) Priority in the range 0 to 255, 192 by default                                                  |
| <i>-seconds</i>                                  | (Optional) Interval in the range 0 to 16383 seconds, 60s by default                                        |
| <i>access_list</i>                               | (Optional) Numerical ACL in the range 1 to 99 or name ACL. By default, all multicast groups are permitted. |

**Defaults**

No C-RP is configured by default.

**Command**

Global configuration mode

**Mode****Usage Guide**

In the PIM-SM protocol, the shared tree RPT created by the multicast routing uses the Rendezvous Point (RP) as the root node. RP is elected by the candidate RPs. After BSR is elected, all C-RPs sends C-RP messages in the unicast form to BSR regularly, and BSR spreads the messages throughout the PIM domain.

To specify an interface as the candidate RP of a specific group, execute this command with ACL. Note that the group range is calculated only based on the permit rule, not the deny rule.

**Configuration**

The following example configures the C-RP.

**Examples**

```
Ruijie# configure terminal
```

```
Ruijie(config)# ip pim rp-candidate g 0/3 priority 200 group-list 3 interval 70
Ruijie(config)# access-list 3 permit 255.1.1.1 0.0.0.255
```

## 6.26 ip pim rp-register-kat

Use this command to set the KAT interval on the RP.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim rp-register-kat** *seconds*

**no ip pim rp-register-kat**

**default ip pim rp-register-kat**

**Parameter Description**

| Parameter      | Description                                                        |
|----------------|--------------------------------------------------------------------|
| <i>seconds</i> | KAT timer time in the range from 1 to 65525 in the unit of seconds |

**Defaults** The default is 210 seconds.**Command Mode** Global configuration mode**Usage Guide** This command is used to configure the KAT interval of RP.**Configuration Examples** The following example sets the KAT interval on the RP to 250 seconds.

```
Ruijie# configure terminal
Ruijie(config)# ip pim rp-register-kat 250
```

## 6.27 ip pim sparse-mode

Use this command to enable PIM-SM on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim sparse-mode**

**no ip pim sparse-mode**

**default ip pim sparse-mode**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

### Defaults

This function is disabled by default.

### Command Mode

Interface configuration mode

### Usage Guide

This command is used to enable PIM-SM on the interface.

- ✓ You need to enable multicast routing forwarding in the global configuration mode before enabling PIM-SM. Otherwise, multicast packets cannot be forwarded even though you enable PIM-SM.
- ✓ During the execution of this command, if the prompt "Failed to enable PIM-SM on <Interface Name>, resource temporarily unavailable, please try again" appears, re-execute this command.
- ✓ During the execution of this command, if the prompt "PIM-SM Configure failed! VIF limit exceeded in NSM!!!" appears; it indicates the allowed configured interface number exceeds the upper limit of the multicast interfaces. In this case, if you still need to enable PIM-SM on the interface, delete the unnecessary PIM-SM, PIM-DM or DVMRP interfaces.

**Configuration** The following example enables PIM-SM on the interface.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ip pim sparse-mode
```

### Related Commands

## 6.28 ip pim spt-threshold

Use this command to enable the SPT switching function.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim spt-threshold** [ **group-list** *access-list* ]

**no ip pim spt-threshold** [ **group-list** *access-list* ]

**default ip pim spt-threshold** [ **group-list** *access-list* ]

### Parameter Description

| Parameter          | Description                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access_list</i> | (Optional) Numerical ACL in the range 1 to 99 and 1300 to 1999 or name ACL. By default, all multicast groups are permitted for SPT switching. |

### Defaults

This function is disabled by default.

### Command Mode

Global configuration mode

### Usage Guide

This command is used to enable the RP tree-to-SPT tree switching function in a specific multicast group range (using **group-list**) or all multicast groups (not using **group-list**) .

### Configuration

The following example enables the SPT switching function.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# ip pim spt-threshold
Ruijie(config)# ip pim spt-threshold group-list 12
Ruijie(config)# access-list 12 permit 225.1.1.1 0.0.0.255
```

### Description

## 6.29 ip pim ssm

Use this command to enable SSM and set the SSM group address range.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim ssm** { **default** / **range** *access\_list* }

**no ip pim ssm**

**default ip pim ssm**

| Parameter<br>Description | Parameter                       | Description                                                      |
|--------------------------|---------------------------------|------------------------------------------------------------------|
|                          | <b>default</b>                  | Multicast groups of 232/8                                        |
|                          | <b>range</b> <i>access_list</i> | Numerical ACL in the range 1 to 99 and 1300 to 1999 or name ACL. |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to enable PIM-SSM (or in some specific multicast groups).

**Configuration** The following command enables SSM and sets the SSM group range to 232/8:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim ssm default

The following command sets the source-specific multicast with ACL 10.
Ruijie(config)# ip pim ssm range 10
Ruijie(config)# access-list 10 permit 232.0.0.1 0.0.0.255
```

**Description**

## 6.30 ip pim triggered-hello-delay

Use this command to configure Triggered-Hello-Delay time on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim triggered-hello-delay** *seconds*

**no ip pim triggered-hello-delay**

**default ip pim triggered-hello-delay**

| Parameter<br>Description | Parameter               | Description                                      |
|--------------------------|-------------------------|--------------------------------------------------|
|                          | <i>interval-seconds</i> | In the range from 1 to 5 in the unit of seconds. |

**Defaults** The default is 5 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to configure the triggered-hello-delay of the interface. When the interface starts or detects a new neighbor, it uses the trigger-hello-delay to generate random time, and then the interface sends the Hello message in random time.

**Configuration** The following command sets the triggered-hello-delay to 3 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ip pim triggered-hello-delay 3
```

## 6.40 show ip pim sparse-mode track

Use this command to display the number of sent and received PIM packets during the period from the beginning of the statistics till now.

**show ip pim sparse-mode track**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command is used to display the number of sent and received PIM packets during the period from the beginning of the statistics till now.. When the system starts up, it sets the start time of the statistics. The start time of the statistics is reconfigured and the PIM packet counter is cleared on calling the **clear ip pim sparse-mode track** every time.

**Configuration Examples** The following example displays the number of sent and received PIM packets during the period from the beginning of the statistics till now.

```
Ruijie # show ip pim sparse-mode track
          PIM packet counters track
Elapsed time since counters cleared: 00:04:03
          received      sent
Valid PIMSM packets:    0          8
Hello:                  0          8
Join-Prune:             0          0
Register:               0          0
Register-Stop:          0          0
Assert:                 0          0
BSM:                    0          0
C-RP-ADV:               0          0
PIMDM-Graft:            0
PIMDM-Graft-Ack :       0
PIMDM-State-Refresh:    0
Unknown PIM Type:       0
Errors:
Malformed packets:          0
Bad checksums:              0
Send errors:                0
Packets received with unknown PIM version:    0
```

## 7 PIM-SMv6 Commands

### 7.1 clear ipv6 mroute

Use this command to clear multicast routing entries.

**clear ipv6 mroute** { \* | *ipv6\_group\_address* | *ipv6\_group\_address ipv6\_source\_address* }

| Parameter Description | Parameter                                          | Description                                                                          |
|-----------------------|----------------------------------------------------|--------------------------------------------------------------------------------------|
|                       | *                                                  | Deletes all the multicast routing entries.                                           |
|                       | <i>ipv6_group_address</i>                          | Deletes the multicast routing entries of the specific group.                         |
|                       | <i>ipv6_group_address</i><br><i>source_address</i> | Deletes the multicast routing entries of the specific group and source IPv6 address. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Multicast routing entries can be deleted manually.

**Configuration** The following example clears the multicast routing entries.

**Examples**

```
Ruijie# clear ipv6 mroute *
Ruijie# clear ipv6 mroute ff66::6666
Ruijie# clear ipv6 mroute ff66::6666 3333::3333
```

### 7.2 clear ipv6 mroute statistics

Use this command to delete the statistics of the multicast routing entries.

**clear ipv6 mroute statistics** { \* | *ipv6\_group\_address*[*ipv6\_source\_address*] }

| Parameter Description | Parameter | Description                                              |
|-----------------------|-----------|----------------------------------------------------------|
|                       | *         | Deletes the statistics of all multicast routing entries. |

|                                                         |                                                                                                        |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <i>ipv6_group_address</i>                               | Deletes the statistics of the multicast routing entries of the specific group.                         |
| <i>ipv6_group_address</i><br><i>ipv6_source_address</i> | Deletes the statistics of the multicast routing entries of the specific group and source IPv6 address. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** The statistics of multicast routing entries can be deleted manually.

**Configuration** The following example deletes the statistics of the multicast routing entries.

**Examples**

```
Ruijie# clear ipv6 mroute statistics *
Ruijie# clear ipv6 mroute statistics ff66::6666
Ruijie# clear ipv6 mroute statistics ff66::6666 3333::3333
```

## 7.3 clear ipv6 pim sparse-mode bsr rp-set

Use this command to clears the RP information learnt dynamically.

**clear ipv6 pim sparse-mode bsr rp-set \***

**Parameter Description**

| Parameter | Description        |
|-----------|--------------------|
| *         | Clears all RP-SET. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** All the RP information learnt dynamically can be cleared manually.

**Configuration** The following example clears the RP information learnt dynamically.

**Examples**

```
Ruijie# clear ipv6 pim sparse-mode bsr rp-set *
```

## 7.6 ipv6 pim accept-crp list

Use this command to confine the C-RP address range and the multicast group address range it serves. Use the no or default form of this command to restore the default setting,

**ipv6 pim accept-crp list** *ipv6\_access-list*

**no ipv6 pim accept-crp**

**default ipv6 pim accept-crp-with-null-group**

|                               |                                                                                                                                                                                            |                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| <b>Parameter Description</b>  | <b>Parameter</b>                                                                                                                                                                           | <b>Description</b> |
|                               | <b>list</b> <i>ipv6_access-list</i>                                                                                                                                                        | Extended IPv6 ACL  |
| <b>Defaults</b>               | No address is filtered by default.                                                                                                                                                         |                    |
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                                                  |                    |
| <b>Usage Guide</b>            | With this command configured on the candidate BSR, when this BSR becomes the elected BSR, it is able to limit the address range of the legal C-RP and the multicast group range it serves. |                    |
| <b>Configuration Examples</b> | The following example confines the C-RP address range and the multicast group address range it serves..                                                                                    |                    |

```
Ruijie (config)# configure terminal
Ruijie (config)# ipv6 pim accept-crp list crp-list
```

## 7.7 ipv6 pim accept-crp-with-null-group

Use this command to receive the C-RP-ADV packets whose prefix-count is 0. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim accept-crp-with-null-group**  
**no ipv6 pim accept-crp-with-null-group**  
**default ipv6 pim accept-crp**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command  
Mode** Global configuration mode

**Usage Guide** With this command configured on the candidate BSR, when this BSR becomes the elected BSR, it is able to receive the C-RP-ADV packets whose prefix-count is 0, and considers this C-RP supports all groups.

**Configuration** The following example receives the C-RP-ADV packets whose prefix-count is 0.

**Examples**

```
Ruijie (config)# configure terminal
Ruijie (config)# ipv6 pim accept-crp-with-null-group
```

**Description**

## 7.8 ipv6 pim accept-register list

Use this command to confine the address range of the (S,G) entry of the register packets. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim accept-register** { **list** *ipv6\_access-list* [ **route-map** *map-name* ] | **route-map** *map-name* [ **list** *ipv6\_access-list* ] }

**no ipv6 pim accept-register**

**default ipv6 pim accept-register**

### Parameter Description

| Parameter                           | Description                             |
|-------------------------------------|-----------------------------------------|
| <b>list</b> <i>ipv6_access-list</i> | Access control list supporting name ACL |
| <b>route-map</b> <i>map-name</i>    | Defines the routing map rule            |

**Defaults** The range is not confined by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to confine the source IPv6 address of register messages on RP. If the unauthorized register source is received, the RP will return the Register-Stop message immediately.

**Configuration Examples** The following example confines the source IPv6 address of register packets on the RP.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim accept-register list register-access-list
Ruijie(config)# ipv6 access-list register-access-list
The following example denies the register message of the specified source
fe80::2d0:f8ff:fe22:33ad
Ruijie(config-ipv6-acl)# deny ipv6 fe80::2d0:f8ff:fe22:33ad/128 any
```

### Related Commands

**Description**

## 7.9 ipv6 pim bsr-border

Use this command to configure the BSR border. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim bsr-border**

**no ipv6 pim bsr-border**  
**default ipv6 pim bsr-border**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** No BSR border is configured by default.

**Command  
Mode** Interface configuration mode

**Usage Guide** To restrain BSM flooding, configure BSR border on the interface so that the interface drops BSM packets upon receiving them and the BSM packets are not forwarded from this interface.

**Configuration** The following example sets the BSR border on the interface *g 0/3*.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ipv6 pim bsr-border
```

## 7.10 ipv6 pim bsr-candidate

Use this command to configure the C-BSR. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim bsr-candidate** *interface-type interface-number* [ *hash-mask-length* [ *priority-value* ] ]

**no ipv6 pim bsr-candidate**

**default ipv6 pim bsr-candidate**

**Parameter  
Description**

| Parameter                                        | Description                                                                                                |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | Interface type and number.                                                                                 |
| <i>hash-mask-length</i>                          | (Optional) HASK mask length configured for electing the RP in the range from 0 to 128. The default is 126. |
| <i>priority-value</i>                            | (Optional) Priority configured for the candidate BSR in the range from 0 to 255. The default is 64.        |

**Defaults** No C-BSR is configured by default.

**Command Mode** Global configuration mode

**Usage Guide** A PIM-SMv6 domain must contain a unique BootStrap Router (BSR). BSR is responsible for collect and issue RP information. A unique recognized BSR is elected among multiple candidate BSRs through the bootstrap packet. Before BSR information is available, C-BSRs consider them to be the BSR, and regularly send bootstrap packets using the multicast address 224.0.0.13 in the PIM-SM domain. This packet contains the address and priority of the BSR.

This command allows the device to send a bootstrap message to all the PIM neighbors using the assigned BSR address. Each neighbor compares the original BSR address with the address in the received bootstrap message. If the IPv6 address of the received address is equal to or larger than the original address, each neighbor saves this received address as the BSR address. Otherwise, they will discard this message.

The current device considers itself to be BSR until it receives a bootstrap message from another candidate BSR and is notified that it has a higher priority value (or the same priority value, but with a larger IPv6 address).

**Configuration** The following example s configures the C-BSR.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim bsr-candidate g 0/3 30 100
```

## 7.11 ipv6 pim dr-priority

Use this command to configure the DR priority, Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim dr-priority** *priority-value*

**no ipv6 pim dr-priority**

**default ipv6 pim dr-priority**

**Parameter Description**

| Parameter             | Description                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------|
| <i>priority-value</i> | The larger the value, the higher the priority is. The range is from 0 to 4294967294. The default is 1. |

**Defaults** The default is 1.

**Command Mode** Interface configuration mode

**Usage Guide** To select a DR:

- If the priority parameter of the Hello message is set for the devices in a LAN, the one of the highest priority is elected to be the DR. If several devices has the same priority, the one of the largest IP address is elected to be the DR.
- If the priority parameter of the Hello message is not set for the devices in a LAN, the one of the largest IP address is elected to be the DR.

**Configuration** The following example configures the DR priority.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ipv6 pim dr-priority 11234
```

## 7.12 ipv6 pim ignore-rp-set-priority

Use this command to ignore the RP priority. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim ignore-rp-set-priority**

**no ipv6 pim ignore-rp-set-priority**

**default ipv6 pim ignore-rp-set-priority**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** By default, the C-RP with higher priority is selected.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to ignore the priority of the RP corresponding to the multicast group.

**Configuration** The following example ignores the RP priority.

**Examples**

```
Ruijie# configure terminal
Ruijie(config-if)# ipv6 pim ignore-rp-set-priority
```

**Command** Global configuration mode  
**Mode**

**Usage Guide** This command is used to set the interval to send the Join/Prune message.

**Configuration** The following example sets the interval to send the Join/Prune message to 100 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim jp-timer 100
```

**Related  
Commands**

**Platform** N/A  
**Description**

## 7.14 ipv6 pim neighbor-filter

Use this command to confine the neighbor address range. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim neighbor-filter** *ipv6\_access-list*

**no ipv6 pim neighbor-filter** *ipv6\_access-list*

**default ipv6 pim neighbor-filter** *ipv6\_access-list*

| Parameter<br>Description | Parameter               | Description                             |
|--------------------------|-------------------------|-----------------------------------------|
|                          | <i>ipv6_access_list</i> | Access control list supporting name ACL |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Neighbor filtering can enhance the security of a PIM-enabled network and provide neighbor restriction. As long as a neighbor is denied by the access list, PIM-SM will not establish the peering relationship with this neighbor or terminate the established peering relationship with this neighbor.

**Configuration Examples** The following example block the neighbor address fe80::2d0:f8ff:fe22:33ad/128.

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ipv6 pim neighbor-filter acl
Ruijie(config-if)# exit
Ruijie(config-if)# ipv6 access-list acl
The following example denies the neighbor fe80::2d0:f8ff:fe22:33ad
Ruijie(config-ipv6-acl)# deny ipv6 fe80::2d0:f8ff:fe22:33ad/128 any
```

## 7.15 ipv6 pim neighbor-tracking

Use this command to disable join restraint on the interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim neighbor-tracking**

**no ipv6 pim neighbor-tracking**  
**default ipv6 pim neighbor-tracking**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

This function is enabled by default.

**Command  
Mode**

Interface configuration mode

**Usage Guide**

Use this command to disable join restraint on the interface. With join constraint enabled, the interface is constrained not to send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. On the other hand, with join constrain disabled, the interface will send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. This function allows upstream routers to track how many receivers in downstream in accord with all received Join messages.

**Configuration**

The following example disables join restraint on the interface.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ipv6 pim neighbor-tracking
```

**Related  
Commands**

**Description**

## 7.16 ipv6 pim override-interval

Use this command to set the override-interval on the interface, Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim override-interval** *milliseconds*

**no ipv6 pim override-interval**

**default ipv6 pim override-interval**

**Parameter  
Description**

| Parameter                    | Description                                         |
|------------------------------|-----------------------------------------------------|
| <i>interval-milliseconds</i> | In the range 1 to 65535 in the unit of milliseconds |

**Defaults** The default is 2500 milliseconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to set the override-interval for the interface.

Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

**Configuration** The following example sets the override-interval to 3000 milliseconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config)# ipv6 pim override-interval 3000
```

**Related Commands**

**Description**

## 7.17 ipv6 pim probe-interval

Use this command to set the register probe interval. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim probe-interval** *seconds*

**no ipv6 pim probe-interval**

**default ipv6 pim probe-interval**

**Parameter Description**

| Parameter      | Description                                         |
|----------------|-----------------------------------------------------|
| <i>seconds</i> | In the range from 1 to 65535 in the unit of seconds |

**Defaults** The default is 5 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to set the registration probe time. The DR can send the null registration message to the RP in a period before the registration suppression time expires. This period is called probe time of null registration packet.

- ✔ The probe time must be less than half of registration suppression time. Furthermore, 3\* registration suppression time plus registration probe time should be no more than 65535s or otherwise the system triggers an alarm.

**Configuration** The following example sets the probe time as 6 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim probe-interval 6
```

**Related  
Commands**

**Platform** N/A  
**Description**

## 7.18 ipv6 pim propagation-delay

Use this command to set the propagation-delay on the interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim propagation-delay** *milliseconds*

**no ipv6 pim propagation-delay**

**default ipv6 pim propagation-delay**

**Parameter  
Description**

| Parameter                    | Description                                              |
|------------------------------|----------------------------------------------------------|
| <i>interval-milliseconds</i> | In the range from 1 to 32765 in the unit of milliseconds |

**Defaults** The default is 500 milliseconds.

**Command  
Mode** Interface configuration mode

**Usage Guide** Use this command to set the propagation-delay for the interface.

- ✔ Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

**Configuration** The following example sets the propagation delay to 600 milliseconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config)# ipv6 pim propagation-delay 600
```

| Related<br>Commands | Command                           | Description |

**Platform** N/A

**Description**

## 7.19 ipv6 pim query-interval

Use this command to set the interval to send the hello packets. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim query-interval** *seconds*

**no ipv6 pim query-interval**

**default ipv6 pim query-interval**

| Parameter<br>Description | Parameter      | Description                                                                            |
|--------------------------|----------------|----------------------------------------------------------------------------------------|
|                          | <i>seconds</i> | Interval to send the Hello message in the range from 1 to 65535 in the unit of seconds |

**Defaults** The default is 30.

**Command Mode** Interface configuration mode

**Usage Guide** Upon updating the interval to send the Hello message, the time of holding the Hello message is updated by the following principle: The hold time is updated to be 3.5 times the transmission interval. If the transmission interval\*3.5 is more than 65535, the hold time is updated to 18725.

**Configuration Examples** The following example sets the interval to send the hello packets.

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config)# ipv6 pim query-interval 60
```

**Description**

## 7.20 ipv6 pim register-checksum-wholepkt

Use this command to calculate the checksum of the whole register packet. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-checksum-wholepkt** [ **group-list** *ipv6\_access-list* ]

**no ipv6 pim register-checksum-wholepkt** [ **group-list** *ipv6\_access-list* ]

**default ipv6 pim register-checksum-wholepkt** [ **group-list** *ipv6\_access-list* ]

### Parameter Description

| Parameter                          | Description                                                                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| group-list <i>ipv6_access-list</i> | Access-list: access control list supporting name ACL.<br>Group-list <i>ipv6_access-list</i> :all multicast packets use this configuration by default |

### Defaults

By default, the checksum of register messages calculates the head of PIM message and register message rather than the whole PIM message.

### Command Mode

Global configuration mode

### Usage Guide

Some vendors calculate checksum based on the overall registration packets. Ruijie Networks introduces this function for the compatibility with these vendors.

### Configuration Examples

The following example calculates the checksum of the whole register packet.

```
Ruijie# configure terminal
Ruijie(config)#ipv6 pim register-checksum-wholepkt group-list
checksum-access-list
Ruijie(config)# ipv6 access-list 99 checksum-access-list
Ruijie(config-ipv6-acl)# permit ipv6 any ff66::6666/64
```

### Description

## 7.21 ipv6 pim register-rate-limit

Use this command to limit the rate of register packets. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-rate-limit** *rate*

**no ipv6 pim register-rate-limit**  
**default ipv6 pim register-rate-limit**

**Parameter  
Description**

| Parameter   | Description                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------|
| <i>rate</i> | Maximum number of register packets that can be sent per second, in the range from 1 to 65535. |

**Defaults**

By default, there is no rate limitation on register messages.

**Command  
Mode**

Global configuration mode

**Usage Guide**

This command is used to configure speed of transmitting register packet in each (S, G) status, not the speed of transmitting register packets in the system. Using this command will decrease the load of source DR and RP. The register packets can be transmitted at the speed within the limit.

**Configuration**

The following example limits the rate of register packets.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim register-rate-limit 3000
```

## 7.22 ipv6 pim register-rp-reachability

Use this command to check RP reachability before sending register packets. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-rp-reachability**  
**no ipv6 pim register-rp-reachability**  
**default ipv6 pim register-rp-reachability**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

By default, the RP reachability is not checked before sending register packets.

**Command**

Global configuration mode

**Mode**

**Usage Guide** This command is used to check the RP reachability before transmission. If not, register packets are not transmitted.

**Configuration** The following example checks the RP reachability before sending register packets.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim register-rp-reachability
```

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform** N/A  
**Description**

## 7.23 ipv6 pim register-source

Use this command to specify the source IPv6 address in the register packets. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-source** { *ipv6\_local\_address* | *interface-type interface-number* }

**no ipv6 pim register-source**

**default ipv6 pim register-source**

**Parameter  
Description**

| Parameter                                        | Description                                                                         |
|--------------------------------------------------|-------------------------------------------------------------------------------------|
| <i>ipv6_local_address</i>                        | Source IPv6 address of register packets                                             |
| <i>interface-type</i><br><i>interface-number</i> | Interface whose IPv6 address is used as the source IPv6 address of register packets |

**Defaults** By default, the source IPv6 address of register packets is the IPv6 address of the DR interface connecting the multicast source.

**Command** Global configuration mode  
**Mode**

**Usage Guide** This command is used to configure the source IPv6 address of register messages. The source IPv6 address must be reachable. When RP receives the register packet, it transmits Register-Stop packet, using its source IPv6 address as the destination IPv6 address of the Register-Stop packet.

It is not necessary to enable the PIM-SMv6 on the associated interfaces.

**Configuration** The following example configures the source IPv6 address of register messages.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim register-source 3333::3333
Ruijie(config)# ipv6 pim register-source g 0/3
```

**Description**

## 7.24 ipv6 pim register-suppression

Use this command to set the register suppression time. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-suppression** *seconds*

**no ipv6 pim register-suppression**

**default ipv6 pim register-suppression**

**Parameter  
Description**

| Parameter          | Description                                                           |
|--------------------|-----------------------------------------------------------------------|
| <i>suppression</i> | Suppression time in the range from 1 to 65535 in the unit of seconds. |

**Defaults**

The default is 60 seconds.

**Command  
Mode**

Global configuration mode

**Usage Guide**

Executing this command on the DR will change the register packet suppression time configured. if the ipv6 pim rp-register-kat command is not configured, executing this command on RP will modify the period of RP keepalive.

**Configuration**

The following example sets the register packet suppression time.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim register-suppression 100
```

**Description**

## 7.25 ipv6 pim rp-address

Use this command to configure the static RP. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim rp-address** *ipv6\_rp-address* [ *ipv6\_access\_list* ]

**no ipv6 pim rp-address** *ipv6\_rp-address* [ *ipv6\_access-list* ]

**default ipv6 pim rp-address** *ipv6\_rp-address* [ *ipv6\_access-list* ]

### Parameter Description

| Parameter               | Description                             |
|-------------------------|-----------------------------------------|
| <i>ipv6_rp-address</i>  | IPv6 address of RP                      |
| <i>ipv6_access_list</i> | Access control list supporting name ACL |

### Defaults

No IPv6 address is configured for the static RP by default.

### Command Mode

Global configuration mode

### Usage Guide

This system supports the configuration of multicast static RP, as well as the configuration of static RP and BSR mechanisms at the same time. When you use this command, note that:

- If both the BSR mechanism and the static RP configuration take effect, the dynamic configuration takes precedence.
- You can configure multiple multicast groups (using ACL) or all multicast groups (not using ACL) for the static RP. But a static RP can be configured only once.
- If there are more than one static RP in a multicast group, the one of the highest IPv6 address is used.
- Only the addresses permitted by ACL are valid multicast groups. By default, all the multicast groups 224/4 are permitted.
- After configuration is performed, the static RP's source IPv6 address is inserted to the group range-based static RP group tree structure. Each group range-based static multicast group maintains the chain list structure of a static RP group. This chain list is sorted in descending order of IPv6 address. When you select a RP from a static RP group, the first entry, namely the one with the largest IPv6 address, will be selected first.

Deleting a static IPv6 address also deletes this address from all the existing static RP groups and selects one from in the existing RP group tree structure as the RP address.

**Configuration** The following example configures the RP static address.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim rp-address 3333::3333 acl
Ruijie(config)# ipv6 pim rp-address 210.34.0.55 4
Ruijie(config)# ipv6 access-list ac
```

```
Ruijie(config)# permit ipv6 any ff66::6666/64
```

#### Related Commands

#### Description

## 7.26 ipv6 pim rp-candidate

Use this command to configure the C-RP. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim rp-candidate** *interface-type interface-number* [ **priority** *priority-value* ] [ **interval** *interval-seconds* ] [ **group-list** *ipv6\_access-list* ]

**no ipv6 pim rp-candidate** [ *interface-type interface-number* ]

**default ipv6 pim rp-candidate** [ *interface-type interface-number* ]

#### Parameter Description

| Parameter                                        | Description                                                                            |
|--------------------------------------------------|----------------------------------------------------------------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | Interface type and interface number                                                    |
| <i>priority-value</i>                            | (Optional) Priority in the range from 0 to 255, 192 by default                         |
| <i>interval-seconds</i>                          | (Optional) Interval in the range from 0 to 16383 in the unit of seconds, 60 by default |
| <i>ipv6_access_list</i>                          | (Optional) ACL name.<br>By default, all multicast groups are permitted.                |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** In the PIM-SMv6 protocol, the shared tree RPT created by the multicast routing uses the Rendezvous Point (RP) as the root node. RP is elected by the candidate RPs. After BSR is elected, all C-RPs sends C-RP messages in the unicast form to BSR regularly, and BSR spreads the messages throughout the PIM domain.

To specify an interface as the candidate RP of a specific group, execute this command with ACL. Note that the group range is calculated only based on the permit rule, not the deny rule.

**Configuration** The following example configures the RP candidate.

**Examples** Ruijie# configure terminal

```
Ruijie(config)# ipv6 pim rp-candidate g 0/3 priority 200 group-list acl interval 40
Ruijie(config)# ipv6 access-list acl
Ruijie(config-ipv6-acl)# permit ipv6 any ff66::6666/64
```

## 7.29 ipv6 pim sparse-mode

Use this command to enable PIM-SMv6 on the interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim sparse-mode**

**no ipv6 pim sparse-mode**

**default ipv6 pim sparse-mode**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command is used to enable PIM-SMv6 on the interface.

- ✓ You need to enable multicast routing forwarding in the global configuration mode before enabling PIM-SMv6. Otherwise, multicast packets cannot be forwarded even though you enable PIM-SM.
- ✓ During the execution of this command, if the prompt "Failed to enable PIM-SMv6 on <Interface Name>, resource temporarily unavailable, please try again" appears, re-execute this command.
- ✓ During the execution of this command, if the prompt "PIM-SMv6 Configure failed! VIF limit exceeded in NSM!!!" appears, it indicates the allowed configured interface number exceeds the upper limit of the multicast interfaces. In this case, if you still need to enable PIM-SMv6 on the interface, delete the unnecessary PIM-SMv6, or PIM-DMv6 interfaces.
- ✓ If the interface is of tunnel-type, only 6Over4 configuration tunnel, 6Over GRE tunnel, 6Over4 configuration tunnel and 6Over6 GRE tunnel support the IPv6 multicasting at the moment. The multicasting can also be enabled on other tunnel interfaces which do not support the multicasting, but no error message will be displayed and no multicast packets will be received and forwarded.
- ✓ The multicast tunnel can only be built on the Ethernet interface, the nested tunnel and the multicast data Qos/ACL are not supported.

**Configuration** The following example enables PIM-SMv6 on the interface.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ipv6 pim sparse-mode
```

**Description**

## 7.30 ipv6 pim spt-threshold

Use this command to enable SPT switch. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim spt-threshold** [group-list *ipv6\_access-list*]

**no ipv6 pim spt-threshold** [ group-list *ipv6\_access-list* ]

**default ipv6 pim spt-threshold** [ group-list *ipv6\_access-list* ]

| Parameter Description | Parameter               | Description                                                                                       |
|-----------------------|-------------------------|---------------------------------------------------------------------------------------------------|
|                       | <i>ipv6_access_list</i> | (Optional) supporting name ACL. By default, all multicast groups are permitted for SPT switching. |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to enable the RP tree-to-SPT tree switching function in a specific multicast group range (using group-list) or all multicast groups (not using group-list) .

**Configuration** The following example enables the SPT switch.

**Examples**

```
Ruijie(config)# ipv6 pim spt-threshold acl
Ruijie(config)# ipv6 access-list acl
Ruijie(config-ipv6-acl)# permit ipv6 fe80::2d0:f8ff:fe22:33ad /128
ff66::6666/64
```

| Related Commands | Command                 | Description |

|                  | <b>ipv6 access-list</b> | N/A         |

**Platform Description** N/A

## 7.31 ipv6 pim ssm

Use this command to enable SSM and set the SSM group address range. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim ssm { default / range *ipv6\_access-list* }**

**no ipv6 pim ssm**

**default ipv6 pim ssm**

| Parameter Description | Parameter                            | Description                     |
|-----------------------|--------------------------------------|---------------------------------|
|                       | <b>default</b>                       | Group in the range of FF3x::/32 |
|                       | <b>range <i>ipv6_access-list</i></b> | Supporting name ACL.            |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to enable PIM-SSMv6 (or in some specific multicast groups).

**Configuration** The following example sets the source-specific multicast of the multicast group range acl.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim ssm range acl
```

The following example uses SSM for the source address fe80::2d0:f8ff:fe22:33ad, group range of ff32::3333/64.

```
Ruijie(config-ipv6-acl)# permit ipv6 fe80::2d0:f8ff:fe22:33ad /128
ff32::3333/64
```

**Related Commands**

**Description**

## 7.32 ipv6 pim static-rp-preferred

Use this command to configure a higher priority for static RP over the C-RP, Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim static-rp-preferred**

**no ipv6 pim static-rp-preferred**

**default ipv6 pim static-rp-preferred**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** By default, the priority of the RP elected through BSR mechanism is high than the one configured statically.

**Command Mode** Interface configuration mode

**Usage Guide** With this command configured, the priority of the static RP is higher than the one elected through the BSR mechanism.

**Configuration Examples** The following example configures the priority of the static RP is higher than the one elected through the BSR mechanism.

```
Ruijie# configure terminal
Ruijie(config-if)# ipv6 pim static-rp-preferred
```

**Description**

## 7.33 ipv6 pim triggered-hello-delay

Use this command to configure Triggered-Hello-Delay time on the interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim triggered-hello-delay** *seconds*

**no ipv6 pim triggered-hello-delay**

**default ipv6 pim triggered-hello-delay**

| Parameter<br>Description | Parameter               | Description                                      |
|--------------------------|-------------------------|--------------------------------------------------|
|                          | <i>interval-seconds</i> | In the range from 1 to 5 in the unit of seconds. |

**Defaults** The default is 5 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to configure the triggered-hello-delay of the interface. When the interface starts or detects a new neighbor, it uses the trigger-hello-delay to generate random time, and then the interface sends the Hello message at the random time.

**Configuration Examples** The following example sets the triggered-hello-delay to 3 seconds.

```
Ruijie# configure terminal
Ruijie(config)# interface g 0/3
Ruijie(config-if)# ipv6 pim triggered-hello-delay 3
```

## 7.35 show ipv6 pim sparse-mode bsr-router

Use this command to display the BSR information.

**show ipv6 pim sparse-mode bsr-router**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** Privileged EXEC mode/ Global configuration mode / Interface configuration mode

**Command Mode** Privileged EXEC mode/ global configuration mode / interface configuration mode

**Usage Guide** This command is used to display BSR information.

**Configuration** The following example displays BSR information.

**Examples**

```
Ruijie# show ipv6 pim sparse-mode bsr-router
PIMv2 Bootstrap information
This system is the Bootstrap Router (BSR)
BSR address: 3333::8888
Uptime:00:03:31, BSR Priority: 64, Hash mask length: 126
Next bootstrap message in 00:00:47
Role: Candidate BSR Priority: 64, Hash mask length: 126
State: Elected BSR
Candidate RP: 3333::8888(GigabitEthernet 0/5)
Advertisement interval 60 seconds
Next Cand_RP_advertisement in 00:00:37
```

## 7.36 show ipv6 pim sparse-mode interface

Use this command to display PIM-SMv6 interface information.

**show ipv6 pim sparse-mode interface** [ *interface-type interface-number* [ **detail** ] ]

**Parameter  
Description**

| Parameter                                        | Description                                                                         |
|--------------------------------------------------|-------------------------------------------------------------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | (Optional) Interface name. This command takes effect for all interfaces by default. |
| <b>detail</b>                                    | (Optional) Displays the details of an interface.                                    |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ Global configuration mode / Interface configuration mode

**Usage Guide** This command displays the PIM-SMv6 information on the interface.

**Configuration** The following example displays the PIM-SMv6 interface information.

**Examples**

```
Ruijie #show ipv6 pim sparse-mode interface detail
GigabitEthernet 0/5 (vif 1):
Address fe80::2d0:f8ff:fe22:33ad, DR fe80::2d0:f8ff:fe22:34b3
```

```
Hello period 30 seconds, Next Hello in 6 seconds
Triggered Hello period 5 seconds
Secondary addresses:
  3333::8888
  4444::4444
Neighbors:
  fe80::2d0:f8ff:fe22:34b3
```

## 7.37 show ipv6 pim sparse-mode local-members

Use this command to display the local MLD information on the PIM-SMv6 interface.

**show ipv6 pim sparse-mode local-members** [ *interface-type interface-number* ]

**Parameter  
Description**

| Parameter                                        | Description                                                                         |
|--------------------------------------------------|-------------------------------------------------------------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | (Optional) Interface name. This command takes effect for all interfaces by default. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ global configuration mode / interface configuration mode

**Usage Guide** This command displays the local MLD information on the PIM-SMv6-enabled interface.

**Configuration** The following example displays the local MLD information on the PIM-SMv6 interface.

**Examples**

```
Ruijie (config-if)#show ipv6 pim sparse-mode local-members
PIM Local membership information
GigabitEthernet 0/5:
  (*, ff66::6666) : Include
```

## 7.38 show ipv6 pim sparse-mode mroute

Use this command to display the PIM-SMv6 routing information.

**show ipv6 pim sparse-mode mroute** [ *group-or-source-address* [ *group-or-source-address* ] ]

**Parameter  
Description**

| Parameter                      | Description                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------|
| <i>group-or-source-address</i> | Group address or source address. Two addresses cannot both be the group addresses or the source addresses. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ Global configuration mode / Interface configuration mode

**Usage Guide** This command is used to display route information. Only one group IPv6 address, one source IPv6 address or one group IPv6 address-source IPv6 address pair can be configured at a time. You can also specify no group IP address or source IPv6 address.

**Configuration** N/A

**Examples****Related

## 7.41 show ipv6 pim sparse-mode rp-hash

Use this command to display the RP information corresponding to the group address.

**show ipv6 pim sparse-mode rp-hash** *ipv6-group-address*

**Parameter  
Description**

| Parameter                 | Description        |
|---------------------------|--------------------|
| <i>ipv6_group-address</i> | IPv6 group address |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ Global configuration mode / Interface configuration mode

**Usage Guide** This command displays the information on the RP of the specific group IPv6 address.

**Configuration** The following example displays the RP information corresponding to the group address..

**Examples**

```
Ruijie# show ipv6 pim sparse-mode rp-hash ff66::6666
RP: 3333::8888
Info source: 3333::8888, via bootstrap
PIMv2 Hash Value 126
RP 3333::8888, via bootstrap, priority 192, hash value 1468234650
```

## 7.43 show ipv6 pim sparse-mode track

Use this command to display the number of sent and received PIM packets during the period from the beginning of the statistics till now.

**show ipv6 pim sparse-mode track**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ global configuration mode / interface configuration mode

**Usage Guide** This command is used to display the number of sent and received PIM packets during the period from the beginning of the statistics till now.. When the system starts up, it sets the start time of the statistics. The start time of the statistics is reconfigured and the PIMv6 packet counter is cleared on calling the clear ipv6 pim sparse-mode track every time.

**Configuration Examples** The following example displays the number of sent and received PIM packets during the period from the beginning of the statistics till now.

```
Ruijie# show ipv6 pim sparse-mode track
```

```

PIMv6 packet counters track
Elapsed time since counters cleared: 00:04:03
                                received      sent
Valid PIMSMv6 packets:         0             8
Hello:                          0             8

## 8 MSDP Commands

### 8.1 clear ip msdp peer

Use this command to clear specific MSDP peer. This will clear the connection to the MSDP peer and then reestablish the connection to MSDP peer. The statistics of MSDP peer will be cleared at the same time.

**clear ip msdp peer** *peer-address*

| Parameter<br>Description | Parameter    | Description             |
|--------------------------|--------------|-------------------------|
|                          | peer-address | IP address of MSDP peer |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to clear the TCP connection to the specified MSDP peer and clear all the MSDP peer statistics.

**Configuration** The following example clears MDSP peer of 218.14.5.23.

**Examples** Ruijie# clear ip msdp peer 218.14.5.23

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform Description** This command is supported only on L3 devices.

### 8.2 clear ip msdp sa-cache

Use this command to clear SA cache entries.

**clear ip msdp sa-cache** [ *group-address* ]

| Parameter<br>Description | Parameter     | Description                                                                                                                                                                                                         |
|--------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | group-address | Group address.<br>If the multicast group address is not specified, all SA cache entries will be cleared; if the multicast group address is specified, the SA cache entries of this multicast group will be cleared. |

**Defaults** N/A**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear the SA cache entries learned from MSDP peer. If no multicast group address is specified, all SA cache entries will be cleared.

After SA cache entries are cleared, the MSDP device will need to relearn SA messages.

**Configuration** The following example clears the SA cache entries with the multicast group 224.1.1.1.

**Examples** Ruijie# clear ip msdp sa-cache 224.1.1.1

**Related Commands**

| N/A     | N/A         |

**Platform** This command is supported only on L3 devices.

**Description**

## 8.3 clear ip msdp statistics

Use this command to clear the statistics of MSDP peers without resetting the TCP sessions.

**clear ip msdp statistics** [ *peer-address* ]

**Parameter Description**

| Parameter           | Description                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------|
| <i>peer-address</i> | IP address of MSDP peer whose statistics counters, reset count, and input/output count will be cleared. |

**Defaults** N/A**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear the statistics of MSDP peers and view the new statistics of MSDP peers.

This command can clear the statistics of one or more MDSP peers without resetting the MSDP peer.

**Configuration** The following example clears the statistics of the MSDP peer with IP address being 61.83.1.52.

**Examples** Ruijie# clear ip msdp statistics 61.83.1.52

## 8.4 ip msdp default-peer

Use this command to define a default MSDP peer.

Use **no** or **default** form of this command to restore the default setting.

**ip msdp default-peer** *peer-address* [ **prefix-list** *prefix-list-name* ]

**no ip msdp default-peer** *peer-address*

**default ip msdp default-peer** *peer-address*

**Parameter  
Description**

| Parameter                                  | Description                    |
|--------------------------------------------|--------------------------------|
| <i>peer-address</i>                        | IP address of MSDP peer        |
| <b>prefix-list</b> <i>prefix-list-name</i> | Specifies the BGP prefix list. |

**Defaults** By default, no default MSDP peer is configured.

**Command  
Mode** Global configuration mode

**Usage Guide** The RPF-Peer calculation rule for the specified RP address may leads the loss of RPF-Peer information, which causes that the SA messages are dropped directly without the Peer-RPF check. With a default peer configured, the SA messages are ensured to pass the Peer-RFP check, so that the local host could accept the SA messages to learn the multicast source information carried by the SA messages.

If "prefix-list prefix-list-name" is not specified, all SA messages from the default MSDP peer will be accepted.

If "prefix-list prefix-list-name" is specified, only the SA messages from the RP specified by prefix-list prefix-list-name will be accepted.

If "prefix-list prefix-list-name" is specified but the prefix list is not configured, all SA messages from this default MSDP peer will be accepted.

**Configuration** The following example configures 172.16.33.1 as the default peer.

**Examples**

```
Ruijie(config)# ip msdp peer 172.16.33.1
Ruijie(config)# ip msdp peer 172.16.34.2
Ruijie(config)# ip msdp default-peer 172.16.33.1
```

**Related  
Commands**

| Command             | Description        |
|---------------------|--------------------|
| <b>ip msdp peer</b> | Creates MSDP peer. |

**Platform** This command is supported only on layer-3 device.

**Description**

## 8.5 ip msdp description

Use this command to add descriptive information for MSDP peer.

Use **no** or **default** form of this command to restore the default setting.

**ip msdp description** *peer-address* *text*

**no ip msdp description** *peer-address*

**default ip msdp description** *peer-address*

| Parameter<br>Description | Parameter           | Description                           |
|--------------------------|---------------------|---------------------------------------|
|                          | <i>peer-address</i> | IP address of MSDP peer               |
|                          | <i>text</i>         | Descriptive information for MSDP peer |
|                          |                     |                                       |

**Defaults** No descriptive information is configured for MSDP peer.

**Command  
Mode** Global configuration mode

**Usage Guide** The administrator can configure descriptive information for MSDP peers in order to identify them conveniently.

If the descriptive information A is specified for an MSDP peer, A is displayed. If no descriptive information is specified, "No description" is displayed.

**Configuration** The following example configures the descriptive information for peer 172.17.1.2 as "customer-a".

**Examples** Ruijie(config)# **ip msdp description** 172.17.1.2 customer-a

| Related<br>Commands | Command                  | Description                                         |
|---------------------|--------------------------|-----------------------------------------------------|
|                     | <b>show ip msdp peer</b> | Displays the descriptive information for MSDP peer. |

**Platform** This command is supported only on L3 devices.

**Description**

## 8.6 ip msdp filter-sa-request

Use this command to filter the SA request messages sent from MSDP peer.

Use the **no** or **default** form of this command to restore the default setting.

```
ip msdp filter-sa-request peer-address [ list access-list ]  
no ip msdp filter-sa-request peer-address  
default ip msdp filter-sa-request peer-address
```

**Parameter  
Description**

| Parameter                      | Description                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------|
| <i>peer-address</i>            | IP address of MSDP peer                                                           |
| <b>list</b> <i>access-list</i> | The standard IP access list number or name for limiting multicast group addresses |

**Defaults** All SA request messages from MSDP peer will be accepted and replied.

**Command  
Mode** Global configuration mode

**Usage Guide** Use this command to control which SA request messages will be accepted and replied.  
If no access list is specified, all SA request messages will be ignored. If the access list is specified, only the SA request messages from the multicast group permitted by the access list will be accepted, and other messages will be ignored.

**Configuration  
Examples** The following example configures to filter SA request messages from peer 172.16.223.1 and only accept SA request messages with group address falling within 224.0.1.0-224.0.1.255.

```
Ruijie(config)# ip msdp filter-sa-request 172.16.223.1 list 1  
Ruijie(config)# access-list 1 permit 224.0.1.1 0.0.0.255
```

**Related  
Commands**

| Command             | Description        |
|---------------------|--------------------|
| <b>ip msdp peer</b> | Creates MSDP peer. |

**Platform  
Description** This command is supported only on L3 devices.

## 8.7 ip msdp mesh-group

Use this command to configure a MSDP peer to be a member of a mesh group.  
Use the **no** form of this command to remove the configuration.  
Use the **default** form of this command to restore the default settings.

```
ip msdp mesh-group mesh-name peer-address  
no ip msdp mesh-group mesh-name peer-address  
default ip msdp mesh-group mesh-name peer-address
```

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|              |                                                       |
|--------------|-------------------------------------------------------|
| mesh-name    | Name of mesh group, case sensitive                    |
| peer-address | IP address of MSDP peer to be a member of mesh group. |

**Defaults** No mesh group will be created, and MSDP peers do not belong to any mesh group.

**Command** Global configuration mode  
**Mode**

**Usage Guide** All MSDP peers in the mesh group shall be fully meshed, namely MSDP peer relationship has been established between every two members in the mesh group.  
The SA received by one member of the mesh group won't be forwarded to other members in the same mesh group, thus reducing SA flooding and simplify Peer-RPF forwarding.

**Configuration Examples** The following example configures MSDP peer at address 192.168.1.3 to be a member of the mesh group named "msdp-mesh".

```
Ruijie(config)# ip msdp mesh-group msdp-mesh 192.168.1.3
```

**Related Commands**

| Command                        | Description                             |
|--------------------------------|-----------------------------------------|
| <b>show ip msdp mesh-group</b> | Displays the information of mesh group. |

**Platform** This command is supported only on L3 devices.  
**Description**

## 8.8 ip msdp originator-id

Use this command to allow a speaker that originates a SA message to use the IP address of the interface as the originator address in the SA message.

Use the **no** form of this command to remove this configuration.

Use the **default** form of this command to restore the default setting.

**ip msdp originator-id** *interface-type interface-number*

**no ip msdp originator-id**

**default ip msdp originator-id**

**Parameter Description**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| interface-type   | Interface type and interface number                                                                                                                                                                                                                                                                                              |
| interface-number | The master IP address of this interface will be used as the originator address in the SA messages. If no IP address is configured for this interface, or the interface is shut down, then the originator address in the SA messages won't use the master IP address of this interface, but use the RP address configured by PIM. |

- Defaults** By default, the originator address in SA messages will be the RP address configured by PIM.
- Command Mode** Global configuration mode
- Usage Guide** Under certain circumstances, you may expect to change the originator address in SA messages, such as during Anycast-RP deployment. By this time, you can use this command to modify the originator address in SA messages.

**Configuration Examples** The following example uses the IP address of Loopback0 as the RP address in SA messages.

**Examples** Ruijie(config) # **ip msdp originator-id** *loopback0*

**Related Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

- Platform** This command is supported only on L3 devices.
- Description**

## 8.9 ip msdp password

Use this command to enable MD5 encryption of the TCP connection between MSDP peers.

Use the **no** or **default** form of this command to restore the default setting.

**ip msdp password peer** *peer-address* [ *encryption-type* ] *string*

**no ip msdp password peer** *peer-address*

**default ip msdp password peer** *peer-address*

**Parameter Description**

| Parameter       | Description                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| peer-address    | IP address of MSDP peer                                                                                                                                        |
| encryption-type | Grade of password: 0 (lowest level)-7 (highest level). Currently, only 0 and 7 are supported. The default encryption type is 0.                                |
| string          | The password used for TCP MD5 authentication.<br>Range: up to 80 characters when the encryption type is 0; up to 160 characters when the encryption type is 7. |

- Defaults** MD5 encryption of the TCP connection between MSDP peers is not enabled.
- Command Mode** Global configuration mode
- Usage Guide** When it is needed to authenticate the MSDP peers, you can enable MD5 encryption of TCP

connection between MSDP peers. In such a case, two interconnected MSDP peers must be configured with MD5 authentication with same password, or else the connection will fail.

If the password is configured or changed, the local MSDP device won't terminate the current session, but will try to use the new password to maintain the current session until timeout.

If you have configure the password locally for the MSDP peer but no password is configured on MSDP, the following warning message will be displayed on the console:

```
%TCP-6-BADAUTH: MD5 digest NOT expected but found (200.200.200.6, 39996)->(200.200.200.16, 639)
```

If different MD5 passwords are configured between MSDP peers, the following warning message will be displayed on the console:

```
%TCP-6-BADAUTH: MD5 digest failed for (200.200.200.6, 12302)->(200.200.200.16, 639)
```

If the encryption type is 7, the entered encryption key must be even and not less than 4.

**Configuration** The following example configures the MD5 password of "test" for the MSDP peer of 10.32.43.144.

**Examples** Ruijie(config)# **ip msdp password peer** 10.32.43.144 0 test

**Description**

## 8.10 ip msdp peer connect-source

Use this command to create MSDP peer.

Use **no** or **default** form of this command to remove MSDP peer.

**ip msdp peer** *peer-address* **connect-source** *interface-type interface-number*

**no ip msdp peer** *peer-address*

**default ip msdp peer** *peer-address*

**Parameter  
Description**

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| peer-address                                                | IP address of MSDP peer                                                                                                                                                                                                                                                                                                                          |
| <b>connect-source</b><br>interface-type<br>interface-number | Interface type and interface number.<br>The local MSDP device uses the main address of this interface as the source IP for the TCP connection to the remote MSDP peer.<br>Loopback interface is recommended.<br>If no IP address is configured for this interface, or the interface is shut down, then MSDP peer relation cannot be established. |

**Defaults** No MSDP peer is created.

**Command** Global configuration mode

**Mode**

**Usage Guide** To enable MSDP, MSDP peer must be created.

**Configuration Examples** The following example configures the main address of interface loopback 0 as the source address for establishing MSDP peer relation with 192.168.5.1.

```
Ruijie(config)# ip msdp peer 192.168.5.1 connect-source loopback 0
```

**Related Commands**

| Command                  | Description                               |
|--------------------------|-------------------------------------------|
| <b>show ip msdp peer</b> | Displays the information about MSDP peer. |

**Platform** This command is supported only on L3 devices.

**Description**

## 8.11 ip msdp redistribute

Use this command to configure which (S, G) entries from the multicast routing table can be advertised to MSDP peers.

Use the **no** form of this command to remove this configuration.

Use the **default** form of this command to restore the default settings.

**ip msdp redistribute** [ **list** *access-list-name* ] [ **route-map** *route-map-name* ]

**no ip msdp redistribute**

**default ip msdp redistribute**

**Parameter Description**

| Parameter                              | Description                                                                                                 |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>list</b> <i>access-list-name</i>    | Number or name of an extended IP access list that controls which multicast routes (S, G) can be advertised. |
| <b>route-map</b> <i>route-map-name</i> | Defines route-map.                                                                                          |

**Defaults** All multicast sources (S, G) registered on the local RP will be advertised.

**Command** Global configuration mode

**Mode**

**Usage Guide** After redistribution filtering is configured, the (S, G) information from the local AS or the other AS can be added to the MSDP only through redistribution filtering.

If "**list** *access-list-name*" is specified, only those matched multicast routes (S, G) will be advertised.

If "**route-map** *map-name*" is specified, only multicast routes (S, G) matching the criteria given in

"map-name" will be advertised.

If two keywords are specified, then multicast routes (S, G) matching all conditions will be advertised.

If the "**ip msdp redistribute**" command is configured with no keywords, no multicast sources will be advertised.

**Configuration Examples** The following example configures to only advertise multicast routes with multicast source being 200.200.200.0/24 and group address being 225.1.1.0/24.

```
Router(config)# ip msdp redistribute list 100
Router(config)# ip access-list extended 100
Router(config-ext-nacl)# permit ip 200.200.200.0 0.0.0.255 225.1.1.0
0.0.0.255
```

#### Related Commands

|------------------------------|-------------------------------------------------|
| <b>ip msdp sa-filter in</b>  | Configures the incoming filter for SA messages. |
| <b>ip msdp sa-filter out</b> | Configures the outgoing filter for SA messages. |

**Platform** This command is supported only on L3 devices.

#### Description

## 8.12 ip msdp sa-filter in

Use this command to configure an incoming filter for SA messages.

Use the **no** or **default** form of this command to remove the incoming filter.

**ip msdp sa-filter in** *peer-address* [ **list** *access-list-name* ] [ **route-map** *route-map-name* ] [ **rp-list** *rp-access-list-name* ] [ **rp-route-map** *rp-route-map-name* ]

**no ip msdp sa-filter in** *peer-address*

**default ip msdp sa-filter in** *peer-address*

#### Parameter Description

| Parameter                                    | Description                                                                                                 |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <i>peer-address</i>                          | IP address of MSDP peer                                                                                     |
| <b>list</b> <i>access-list-name</i>          | Number or name of an extended IP access list that controls which multicast routes (S, G) can be received.   |
| <b>route-map</b> <i>route-map-name</i>       | Specify the name of route-map; only SA messages matching the criteria given in "map-name" can pass through. |
| <b>rp-list</b> <i>rp-access-list-name</i>    | Number or name of standard access list that controls RPs.                                                   |
| <b>rp-route-map</b> <i>rp-route-map-name</i> | Specify the name of route map for RP; only the SA messages matching rp-map-name can be accepted.            |

**Defaults** All incoming SA messages will be accepted without filtering.

**Command** Global configuration mode

**Mode**

**Usage Guide** If the command is configured, but no access list or route map is specified, all incoming SA messages will be filtered.

If only the **list** keyword or the **route-map** keyword is used, the multicast source (S, G) in SA messages matching the criteria corresponding to this keyword will be accepted.

If only the **rp-list** keyword or the **rp-route-map** keyword is used, the SA message will be accepted if the RP address carried in SA message matches the criteria corresponding to this keyword.

If two or more keywords of **list**, **route-map**, **rp-list** and **rp-route-map** are used, the SA message will be accepted if any multicast source (S, G) in SA message meet the criteria corresponding to all keywords.

**Configuration** The following example configures that all SA messages from the peer of 10.234.1.43 will be filtered.

**Examples**

```
Ruijie(config)# ip msdp peer 10.234.1.43
Ruijie(config)# ip msdp sa-filter in 10.234.1.43
```

**Related  
Commands**

| <b>ip msdp sa-filter-out</b> | Configures the outgoing filter for SA messages received from MSDP peers. |

**Platform** This command is supported only on L3 devices.

**Description**

## 8.13 ip msdp sa-filter out

Use this command to configure an outgoing filter for SA messages.

Use the **no** or **default** form of this command to remove the outgoing filter.

**ip msdp sa-filter out** *peer-address* [ **list** *access-list-name* ] [ **route-map** *route-map-name* ] [ **rp-list** *rp-access-list-name* ] [ **rp-route-map** *rp-route-map-name* ]

**no ip msdp sa-filter out** *peer-address*

**default ip msdp sa-filter out** *peer-address*

**Parameter  
Description**

| Parameter                                 | Description                                                                                                 |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <i>peer-address</i>                       | IP address of MSDP peer                                                                                     |
| <b>list</b> <i>access-list-name</i>       | Number or name of an extended IP access list that controls which multicast routes (S, G) can be received.   |
| <b>route-map</b> <i>route-map-name</i>    | Specify the name of route-map; only SA messages matching the criteria given in "map-name" can pass through. |
| <b>rp-list</b> <i>rp-access-list-name</i> | Number or name of standard access list that controls RPs.                                                   |
| <b>rp-route-map</b>                       | Specify the name of route map for RP; only the SA messages                                                  |

|                   |                                       |
|-------------------|---------------------------------------|
| rp-route-map-name | matching rp-map-name can be accepted. |
|-------------------|---------------------------------------|

**Defaults** The outgoing SA messages won't be filtered. All SA messages received will be forwarded to the MSDP peer.

**Command Mode** Global configuration mode

**Usage Guide** If the command is configured, but no access list or route map is specified, all SA messages won't be forwarded to this MSDP peer.

If only one keyword of **list**, **route-map**, **rp-list** and **rp-route-map** is used, the multicast source pair (S, G) will be forwarded to this MSDP peer if the criteria corresponding to this keyword are met.

If two or more keywords of **list**, **route-map**, **rp-list** and **rp-route-map** are used, the (S, G) pair will only be forwarded to this MSDP peer if criteria corresponding to all keywords are met.

**Configuration Examples** The following example allows only multicast sources that pass access list 100 to be forwarded to the peer of 10.234.1.43.

```
Ruijie(config)# ip msdp peer 10.234.1.43
Ruijie(config)# ip msdp sa-filter out 10.234.1.43 list 100
Ruijie(config)# access 100 permit ip 10.211.0.0 0.0.255.255 224.12.0.0
0.0.255.255
```

**Related Commands**

| Command                     | Description                                                              |
|-----------------------------|--------------------------------------------------------------------------|
| <b>ip msdp peer</b>         | Configures MSDP peer.                                                    |
| <b>ip msdp sa-filter-in</b> | Configures the incoming filter for SA messages received from MSDP peers. |

**Platform Description** This command is supported only on L3 devices.

## 8.14 ip msdp sa-limit

Use this command to configure the allowable maximum number of SA cache entries from a MSDP peer.

Use the **no** or **default** form of this command to restore the default settings.

**ip msdp sa-limit** *peer-address sa-limit*

**no ip msdp sa-limit** *peer-address*

**default ip msdp sa-limit** *peer-address*

**Parameter Description**

| Parameter    | Description             |
|--------------|-------------------------|
| peer-address | IP address of MSDP peer |

|          |                                                                          |
|----------|--------------------------------------------------------------------------|
| sa-limit | Maximum number of SA messages from an MSDP peer allowed in the SA cache. |
|----------|--------------------------------------------------------------------------|

**Defaults** The maximum number of SA messages from an MSDP peer allowed in the SA cache is not limited.

**Command Mode** Global configuration mode

**Usage Guide** It is suggested to configure this command on all MSDP peers to prevent SA flooding attacks from MSDP peers

**Configuration Examples** The following example configures the SA message limit to 100 for the MSDP peer with IP address being 172.16.3.1.

```
Ruijie(config)# ip msdp sa-limit 172.16.3.1 100
```

**Related Commands**

**Platform Description** This command is supported only on L3 devices.

## 8.15 ip msdp shutdown

Use this command to shut down the connection to MSDP peer.

Use the **no** or **default** form of this command to restore the default settings.

**ip msdp shutdown** *peer-address*

**no ip msdp shutdown** *peer-address*

**default ip msdp shutdown** *peer-address*

**Parameter Description**

| Parameter    | Description             |
|--------------|-------------------------|
| peer-address | IP address of MSDP peer |

**Defaults** The connection to peer is not shut down.

**Command Mode** Global configuration mode

**Usage Guide** Only the TCP connection to the specified MSDP peer will be shut down. Neither the MSDP peer nor its configurations will be cleared.

**Configuration Examples** The following example shuts down the MSDP peer at IP address 192.168.7.20.

```
Ruijie(config)# ip msdp shutdown 192.168.7.20
```

| Related<br>Commands | Command             | Description        |
|---------------------|---------------------|--------------------|
|                     | <b>ip msdp peer</b> | Creates MSDP peer. |

**Platform** This command is supported only on L3 devices.

**Description**

## 8.16 ip msdp timer

Use this command to configure the interval for timer re-connection.

Use the **no** or **default** form of this command to restore the default settings.

**ip msdp timer** *interval*

**no ip msdp time**

**default ip msdp timer**

| Parameter<br>Description | Parameter | Description                                                                 |
|--------------------------|-----------|-----------------------------------------------------------------------------|
|                          | interval  | Interval for timer re-connection, within the range from 1 to 60 (in second) |

**Defaults** The default interval is 30 seconds.

**Command Mode** Global configuration mode

**Usage Guide** By default, the interval for timer re-connection is 30 seconds, that is, the peer in active end can initiate only one TCP connection within 30 seconds. In certain applications, the interval is expected to be decreased in order to accelerate convergence of MSDP peering relation.

**Configuration Examples** The following example sets the interval for timer re-connection to 20 seconds.

```
Ruijie(config)# ip msdp timer 20
```

**Platform** This command is supported only on L3 devices.

**Description**

## 8.17 ip msdp ttl-threshold

Use this command to limit the TTL value of multicast data packets carried in SA messages in order to

limit the transmission of multicast packets.

Use the **no** or **default** form of this command to restore to the default settings.

**ip msdp ttl-threshold** *peer-address ttl-value*

**no ip msdp ttl-threshold** *peer-address*

**default ip msdp ttl-threshold** *peer-address*

| Parameter<br>Description | Parameter    | Description             |
|--------------------------|--------------|-------------------------|
|                          | peer-address | IP address of MSDP peer |
|                          | ttl-value    | TTL value (0-255)       |
|                          |              |                         |

**Defaults** TTL threshold is 0 by default.

**Command Mode** Global configuration mode

**Usage Guide** This command limits multicast data packets which are sent in data-encapsulated SA messages. Only multicast packets with an IP-header TTL greater than or equal to the ttl-value will be sent to the MSDP peer. If the TTL value of multicast data is less than the threshold configured, then the multicast data will be separated from SA messages and discarded, and the SA messages without multicast data will be sent to the MSDP peer.

This command only limits the transmission of multicast data in SA messages without compromising the transmission of multicast sources in SA messages

**Configuration Examples** The following example configures the TTL threshold for peer at IP address 192.168.10.1 to 8 hops:

```
Ruijie(config)# ip msdp ttl-threshold 192.168.10.1 8
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform Description** This command is supported only on L3 devices.

## 8.18 ip msdp peer-limit

Use this command to set the upper limit of MSDP peers.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default settings.

**ip msdp peer-limit** *peer-limit*

**no ip msdp peer-limit**

**default ip msdp peer-limit**

| Parameter<br>Description | Parameter         | Description                                                |
|--------------------------|-------------------|------------------------------------------------------------|
|                          | <i>peer-limit</i> | The upper limit of MSDP peers, in the range from 1 to 128. |

**Defaults** The default is 64.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to set the upper limit of MSDP peers. If the number of existing MSDP peers exceeds the upper limit to be configured, you should delete some peers, or the configuration will fail.

**Configuration Examples** The following example sets the upper limit of MSDP peers to 128.

```
Ruijie(config)# ip msdp peer-limit 128
```

**Platform Description** This command is supported only on L3 devices.

## 8.19 ip msdp global-sa-limit

Use this command to configure the maximum SA cache.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default settings.

**ip msdp global-sa-limit** *sa-limit*

**no ip msdp global-sa-limit** *sa-limit*

**default ip msdp global-sa-limit** *sa-limit*

| Parameter<br>Description | Parameter       | Description                                        |
|--------------------------|-----------------|----------------------------------------------------|
|                          | <i>sa-limit</i> | The maximum SA cache, in the range from 1 to 4,096 |

**Defaults** The default SA cache is 1,024.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to set the maximum SA cache. It's recommended to configure it at the beginning of startup.

When MSDP is running, the increase in maximum SA cache has no influence upon the previously learned entries; the decrease in maximum SA cache will clear all entries learned before and start caching again.

**Configuration** The following example sets the maximum SA cache to 4,096.

**Examples**

```
Ruijie(config)# ip msdp global-sa-limit 4096
```

**Platform**

This command is supported only on L3 devices.

**Description**

## 8.20 show ip msdp count

Use this command to display the number of sources and groups originated in SA messages and the number of SA messages from an MSDP peer in the SA cache.

**show ip msdp count** [ *as-number* ]

**Parameter  
Description**

| Parameter | Description                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------|
| as-number | Display the number of sources and groups originated in SA messages from the specified autonomous system number. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** Ruijie# sh ip msdp count

**Examples**

```
SA State per Peer Counters, <Peer>: <# SA learned>
 1.1.1.2: 0
100.100.100.14 : 0
100.100.100.15 : 0
100.100.100.200: 0
200.200.200.2 : 2
200.200.200.3 : 0
200.200.200.6 : 0
200.200.200.13 : 0
200.200.200.66 : 0

SA State per ASN Counters, <asn>: <# sources>/<# groups>
Total entries: 2
100: 1/2 .
```

| Field             | Description                                                               |
|-------------------|---------------------------------------------------------------------------|
| 200.200.200.200:2 | MSDP peer with IP address 200.200.200.200; 2 SA messages in the SA cache. |

|               |                                                                         |
|---------------|-------------------------------------------------------------------------|
| Total entries | Total number of SA entries in the SA cache.                             |
| ?:1/2         | Unknown autonomous system: 1 source address/2 multicast group addresses |

**Platform** This command is only supported on L3 devices.

#### Description

## 8.25 show ip msdp sa-originated

Use this command to display the (S, G) information to be sent by the local device. The (S, G) information has passed redistribution filtering.

**show ip msdp sa-originated**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command can be used to display the (S, G) information sent by the local device that is the RP in PIM-SM with the multicast source (S, G) registered and is configured with MSDP peer. (S, G) information displayed has passed redistribution filtering, but, whether the information can be sent to the MSDP peer requires the results of egress filtering for the information.

**Configuration** The following is sample output of "show ip msdp sa-originated" command.

#### Examples

```
Ruijie# sh ip msdp sa-originated
MSDP Source-Active Originated: 5 entries
(192.168.23.78, 225.0.0.1), RP: 192.168.23.249
(192.168.23.79, 225.0.0.2), RP: 192.168.23.249
(192.168.23.80, 225.0.0.3), RP: 192.168.23.249
```

```
(192.168.23.81, 225.0.0.4), RP: 192.168.23.249
(192.168.23.82, 225.0.0.5), RP: 192.168.23.249
```

| Field                      | Description                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------|
| (192.168.23.78, 225.0.0.1) | The source address (the first IP address) and group address (the second IP address) of SA to be sent. |
| RP 192.168.23.249          | RP address of SA sent.                                                                                |

**Description**

## 8.26 show ip msdp summary

Use this command to display the summary information about all MSDP peers.

**show ip msdp summary**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** If the local device configured with MSDP peers is the PIM-SM Rendezvous Point (RP) and multicast sources (S,G) registers in the RP, the command will display: (S,G) to Send  
The displayed (S,G) have gone through redistribution filtering (command: **ip msdp redistribute**).  
However, whether these (S,G) will be delivered to MSDP peers successfully relies on the outgoing filter (command: **ip msdp sa-filter out**).

**Configuration Examples** The following example displays the summary information about all MSDP peers.

#### Examples

```
Ruijie# sh ip msdp summary

Msdp Peer Status Summary
Peer Address      As      State      Uptime/Downtime  Reset-Count
Sa-Count  Peer-description
200.200.200.2    100     Up          04:22:11         10          6616
No description
200.200.200.3    100     Down        19:17:13         4           0
```

`peer-A`

| Field           | Description                                      |
|-----------------|--------------------------------------------------|
| Peer Address    | IP address of MSDP peer                          |
| AS              | Autonomous system to which the MSDP peer belongs |
| State           | State of the MSDP peer                           |
| Uptime/Downtime | Up time or down time of MSDP peer                |

## 9 IGMP Snooping Commands

### 9.1 clear ipv6 mld snooping gda-table

Use this command to clear the forwarding table information learned dynamically.

**clear ipv mld snooping gda-table**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear the forwarding table information learned dynamically.

**Configuration Examples** The following example clears the forwarding table information learned dynamically:

```
Ruijie# clear ip mld snooping gda-table
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform Description** N/A

### 9.2 clear ipv6 mld snooping statistics

Use this command to clear the MLD Snooping statistics, including the entry number, the entry volume, the number of various received packets, the group information and the interface information of the corresponding group.

**clear ip mld snooping statistics**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** Use the **show ip mld snooping** command to verify the configuration.

**Configuration** The following example clears the MLD Snooping statistics.

**Examples** Ruijie# clear ip mld snooping statistics

**Related  
Commands**

**Description**

## 9.3 deny

To deny the forwarding of the multicast streams in the range specified by the profile, execute the deny configuration command in the profile configuration mode.

**Parameter** N/A

**Description**

**Default** The forwarding of the multicast streams in the range specified by the profile is denied.

**Command Mode** Profile configuration mode

**Usage Guide** First, configure the multicast range using the range command in the profile configuration mode. In addition, the profile must be applied to the interface in order to make the profile configuration take effect.

**Configuration** The following is an example of deny the forwarding of the multicast stream 224.2.2.2:

**Examples** Ruijie(config)# ip igmp profile 1  
Ruijie(config-profile)# range 224.2.2.2  
Ruijie(config-profile)# deny

| Related Commands | Command         | Description                             |
|------------------|-----------------|-----------------------------------------|
|                  | ip igmp profile | Creates a profile.                      |
|                  | range           | Configures the multicast address range. |

## 9.4 ip igmp profile

This is a mode navigation command. Use this command to select a profile and enter the IGMP profile configuration mode.

**ip igmp profile** *profile-number*

**no ip igmp profile** *profile-number*

| Parameter   | Parameter             | Description                                  |
|-------------|-----------------------|----------------------------------------------|
| Description | <i>profile-number</i> | Profile number, in the range from 1 to 65535 |

**Default** N/A.

**Command Mode** Global configuration mode

**Usage Guide** The profile must be applied to the specified interface in order to make the profile take effect.

**Configuration**

The following is an example of creating a profile numbered 1 and entering the profile configuration mode.

**Examples**

```
Ruijie(config)# ip igmp profile 1
Ruijie(config-profile)#
```

**Related Commands**

| Command | Description                             |
|---------|-----------------------------------------|
| range   | Configures the multicast address range. |

## 9.5 ip igmp snooping

Use this command to enable IVGL mode.

**ip igmp snooping ivgl**

Use this command to enable SVGL mode.

**ip igmp snooping svgl**

Use this command to enable IVGL-SVGL mode.

**ip igmp snooping ivgl-svgl**

Use the **no** form of this command to disable IGMP snooping.

**no ip igmp snooping**

**default ip igmp snooping**

**Parameter**

**Description** N/A.

**Default** Disabled.

**Command**

**Mode** Global configuration mode

**Usage**

**Guide** N/A

**Configuration** The following example demonstrates how to enable IGMP snooping and enter the IVGL mode:

**Examples** Ruijie(config)# ip igmp snooping ivgl

## 9.6 ip igmp snooping dyn-mr-aging-time

To configure the aging time of the routing interface that the switch learns dynamically, execute the **ip igmp snooping dyn-mr-aging-time** command .

**ip igmp snooping dyn-mr-aging-time** *time*

**no ip igmp snooping dyn-mr-aging-time**

| Parameter   | Parameter   | Description                                                            |
|-------------|-------------|------------------------------------------------------------------------|
| Description | <i>time</i> | Aging time of the routing interface that the switch learns dynamically |

**Defaults** 300s.

**Command Mode** Global configuration mode.

**Usage Guide** When the dynamic routing interface learning function is enabled, this command sets the aging time of the routing interface. If the aging time is set too short, the routes may be added and deleted frequently.

**Configuration** Set the aging time of the routing interface that the switch learns dynamically to 100 s:

**Examples** Ruijie(config)# ip igmp snooping dyn-mr-aging-time 100

| Related  | Command                 | Function               |
|----------|-------------------------|------------------------|
| Commands | <b>ip igmp snooping</b> | Enables IGMP snooping. |

## 9.7 ip igmp snooping fast-leave enable

To enable the fast leave function, execute the **ip igmp snooping fast-leave enable** command in the global configuration mode. The **no** form of this command is used to disable the function.

**ip igmp snooping fast-leave enable**

**no ip igmp snooping fast-leave enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       |             |

**Defaults** Disabled.

**Command Mode** Global configuration mode

After you execute this command to enable the fast-leave function, the system will remove the corresponding multicast group on the corresponding interface upon the receipt of the IGMP leave message.

**Usage Guide**

Subsequently, when the system receives a specific group query packet, the system does not forward it to the corresponding interface. Leave packets include IGMPv2 leave packets and IGMPv3 report packets of the include type without source addresses. The fast leave function applies to scenarios in which one interface is connected to only one host. This function saves bandwidth and resources.

**Configuration**

The following example enables the fast leave function on the switch:

**Examples**

```
Ruijie(config)# ip igmp snooping fast-leave
```

**Related  
Commands**

| Command | Function |
|---------|----------|
| N/A     |          |

## 9.8 ip igmp snooping filter

To configure a port to receive a specific set of multicast streams, execute the **ip igmp snooping filter** command in the interface configuration mode to associate the port to a specific profile. The **no** form of this command is used to delete the associated profile.

**ip igmp snooping filter** *profile-number*

**no ip igmp snooping filter** *profile-number*

**Parameter**

**Description**

| Parameter             | Description    |
|-----------------------|----------------|
| <i>profile-number</i> | Profile number |

**Default**

N/A.

**Command Mode**

Global configuration mode or interface configuration mode.

**Usage Guide**

A specific profile must be created before association.

**Configuration**

**Examples**

The following example demonstrates how to associate profile 1 to a megabit port 0/1:

```
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ip igmp snooping filter 1
```

**Related  
Commands**

| Command                | Description       |
|------------------------|-------------------|
| <b>ip igmp profile</b> | Create a profile. |

## 9.9 ip igmp snooping host-aging-time

Use this command to configure the aging time of IGMP dynamic ports. The **no** form of this command is used to restore the default aging time.

**ip igmp snooping host-aging-time** *seconds*

**no ip igmp snooping host-aging-time**

| Parameter   | Parameter      | Description                                                                                 |
|-------------|----------------|---------------------------------------------------------------------------------------------|
| Description | <i>seconds</i> | Aging time. The unit is second. The value ranges from 1 to 65535. The default value is 260. |

**Defaults** 260

**Command Mode** Global configuration mode

**Usage guideline** The aging time of a dynamic port is set by the system when the port receives an IGMP packet from the host for joining a certain IP multicast group.

When such an IGMP packet is received, the system resets the aging timer for the port. The duration of this timer is determined by **host-aging-time**. If the timer expires, the system determines that there is no host in this port for receiving multicast packets. The multicast device removes the port from the IGMP Snooping group. After the **ip igmp snooping host-aging-time** command is executed, the aging time will be determined by **host-aging-time**. This command takes effect only after the system receives the next IGMP packet. This command does not change the current aging time.

**Example** The following example sets the aging time to 30 seconds:

```
Ruijie(config)# ip igmp snooping host-aging-time 30
```

| Related command | Command | Description |
|-----------------|---------|-------------|
|                 | -       | -           |

**Platform** -

**Description**

## 9.10 ip igmp snooping l2-entry-limit

Use this command to set the maximum number of multicast groups. The **no** form of this command is used to cancel the limit.

**ip igmp snooping l2-entry-limit** *number*

**no ip igmp snooping l2-entry-limit**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                        |                                                                                                                                                                                                                                                                                                     |                                                              |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <b>Description</b>     | <i>number</i>                                                                                                                                                                                                                                                                                       | Number of multicast groups. The value ranges from 0 to 4096. |
| <b>Defaults</b>        | 1024                                                                                                                                                                                                                                                                                                |                                                              |
| <b>Command Mode</b>    | Global configuration mode                                                                                                                                                                                                                                                                           |                                                              |
| <b>Usage guideline</b> | The maximum number of multicast groups includes the multicast groups in all ports of all VLANs (including dynamic and static multicast groups). When the number of multicast groups reaches the limit, learning new group records and configuring new static multicast group ports are not allowed. |                                                              |
| <b>Example</b>         | <p>The following example sets the maximum number of multicast groups to 2000:</p> <pre>Ruijie(config)# ip igmp snooping l2-entry-limit 2000</pre>                                                                                                                                                   |                                                              |
| <b>Related command</b> | <b>Command</b>                                                                                                                                                                                                                                                                                      | <b>Description</b>                                           |
|                        | <b>show ip igmp snooping</b>                                                                                                                                                                                                                                                                        | Displays the maximum number of multicast groups.             |

| <b>Description</b>     |                                                                                                                                                                                                                                                                                                     |                                                              |

## 9.11 ip igmp snooping limit-ipmc

To add a multicast source IP address check entry, execute the **ip igmp snooping limit-ipmc** command in the global configuration mode. The **no** form of this command is used to delete a source IP checklist entry.

**ip igmp snooping limit-ipmc** *vlan vid address gaddress server saddress*

**no ip igmp snooping limit-ipmc** *vlan vid address gaddress server saddress*

|                                        | Parameter       | Description                                    |
|----------------------------------------|-----------------|------------------------------------------------|
| <b>Parameter</b><br><b>Description</b> | <i>Vid</i>      | VLAN ID of the source IP address check entry   |
|                                        | <i>Gaddress</i> | Multicast address                              |
|                                        | <i>Saddress</i> | Multicast source IP address (multicast server) |

**Defaults** N/A

**Command Mode**  
Global configuration mode

**Usage**

**Guide** The source IP address check function must be enabled before an entry can be added.

**Configuration Examples** The following example adds an entry to the multicast source IP address check table.

```
Ruijie(config)# ip igmp snooping limit-ipmc vlan 1 address 224.0.0.1 server 192.168.4.243
```

| Related Commands | Command                                             | Description                                                                  |
|------------------|-----------------------------------------------------|------------------------------------------------------------------------------|
|                  | <b>ip igmp snooping source-check default-server</b> | Configures a default source IP address while enabling the IP check function. |

## 9.12 ip igmp snooping max-groups

To configure the maximum number of groups that can be added dynamically to this interface, execute the **ip igmp snooping max-groups** command in the interface configuration mode. The **no** form of this command is used to remove the configuration.

**ip igmp snooping max-groups** *number*

**no ip igmp snooping max-groups**

| Parameter   | Parameter     | Description                           |
|-------------|---------------|---------------------------------------|
| Description | <i>number</i> | The parameter ranges 0 to 4294967294. |

**Defaults** N/A

**Command**

**Mode** Interface configuration mode

**Usage** If a maximum number of multicast groups are configured, the device will no longer receive and process

**Guide** IGMP Report messages when the number of multicast groups on this interface is beyond the range.

The following example configures the maximum number of multicast groups to 100 on the megabit interface 0/1:

**Configuration Examples**

```
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ip igmp snooping max-group 100
```

| Related Commands | Command                        | Description                                        |
|------------------|--------------------------------|----------------------------------------------------|
|                  | <b>ip igmp snooping filter</b> | Filters multicast groups that pass through a port. |

## 9.13 ip igmp snooping mrouter learn pim-dvmrp

To configure a device to listen to the IGMP Query/Dvmrp or PIM Help packets dynamically in order to automatically identify a routing interface, execute the **ip igmp snooping mrouter learn** command in the global configuration mode. The **no** form of this command is used to disable the dynamic learning.

**ip igmp snooping mrouter learn pim-dvmrp**

**no ip igmp snooping mrouter learn pim-dvmrp**

**Defaults** Enabled

## Command

**Mode** Global configuration mode

## Usage Guide

Routing interface is a port through which a multicast device (with IGMP Snooping enabled) is directly connected to a multicast neighbouring device (with multicast routing protocols enabled).

By default, the dynamic routing interface learning function is enabled. You can use the **no** form of this command to disable this function and clear all routing interfaces learnt dynamically. With dynamic routing interface learning function disabled globally, the function of all vlans will be disabled. Beside, with this function enabled globally, if the function of specified vlan is disabled, the dynamic routing interface learning function of the corresponding vlan is disabled. When the source port check function is enabled, only the multicast flow enters from the routing interface is legal and it is forwarded to the registered interface by the multicast equipment, the multicast flow from the non routing interface is considered to be the illegal and is discarded. With the source port check function enabled, the dynamic routing interface learning function will improve the application flexibility of IGMP snooping.

## Configuration Examples

The following example demonstrates how to enable the dynamic routing interface learning function on the equipment:

```
Ruijie(config)# ip igmp snooping mrouter learn pim-dvmrp
```

## Related Commands

| Command                                              | Description                                                                            |
|------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>ip igmp snooping vlan mrouter learn pim-dvmrp</b> | Enables the dynamic routing interface learning function on the multicast routing port. |

## 9.14 ip igmp snooping preview

Allow the user to preview the specific multicast streams when the user doesn't have access to such multicast streams. Use **no** form of this command to disable multicast preview.

**ip igmp snooping preview** *profile-number*

**no ip igmp snooping preview**

## Parameter Description

| Parameter             | Description             |
|-----------------------|-------------------------|
| <i>profile-number</i> | Profile number (1-1024) |

**Defaults** N/A

## Command Mode

Global configuration mode

**Usage** Apply the IGMP Profile to a multicast preview function. When the user doesn't have access to the multicast streams (namely the user might be filtered by IGMP Snooping filter), it can allow the user to preview partial contents. This function shall be used in conjunction with IGMP Snooping filter or multicast control in order to realize effective multicast preview.

**Guide**

**Configuration Examples** The following example associates the profile 1 to the 100M port 0/1 and associates multicast preview with profile 2:

```
Ruijie(config)# ip igmp snooping preview 2
Ruijie(config-if)# int fa 0/1
Ruijie(config-if)# ip igmp snooping filter 1
```

**Related Commands**

| Command         | Description      |
|-----------------|------------------|
| ip igmp profile | Create a profile |

**Platform** This command is supported higher than V10.4 (3).

**Description**

## 9.15 ip igmp snooping preview interval

Use this command to configure the interval that allows the user to preview the specific multicast streams when the user doesn't have access to such multicast streams. Use **no** form of this command to restore the preview interval to the default value.

**ip igmp snooping preview interval** *num*

**no ip igmp snooping preview interval**

| Parameter   | Parameter  | Description                                    |
|-------------|------------|------------------------------------------------|
| Description | <i>num</i> | Preview interval (1-300); default: 60 seconds. |

**Defaults** The default value is 60 seconds.

**Command Mode** Global configuration mode

**Usage Guide** NA

**Configuration Examples** The following example sets the multicast preview interval as 100 seconds on the 100M port of 0/1:

```
Ruijie(config)# ip igmp snooping preview interval 100
```

**Related Commands**

| Command                  | Description                    |
|--------------------------|--------------------------------|
| ip igmp snooping preview | Enables the multicast preview. |

**Platform** N/A

**Description**

## 9.16 ip igmp snooping querier

To enable the IGMP querier function, execute "**ip igmp snooping querier**" global configuration command. Use **no** form of this command to disable IGMP querier in all VLANs and disable the global configurations.

**ip igmp snooping querier**

**no ip igmp snooping querier**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** Disabled.

**Command Mode** Global configuration mode

**Usage Guide** After globally enabling the IGMP querier, you must enable the IGMP querier function in VLAN to affect this command.  
If the IGMP querier function is disabled globally, the IGMP querier will be disabled in all VLANs.

**Configuration Examples** The following example enables the IGMP querier function on the device:

```
Ruijie(config)# ip igmp snooping querier
```

| Related Commands | Command                              | Description                          |
|------------------|--------------------------------------|--------------------------------------|
|                  | <b>ip igmp snooping vlan querier</b> | Enables the querier function in VLAN |

**Platform** N/A

**Description**

## 9.17 ip igmp snooping querier address

To enable the IGMP querier, you also need to specify a source IP address for query packets. Execute the global configuration command of "**ip igmp snooping querier address**". Use **no** form of this command to remove the source IP address configured.

**ip igmp snooping querier address** *a.b.c.d*

**no ip igmp snooping querier address**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |                |                                         |
|--------------------|----------------|-----------------------------------------|
| <b>Description</b> | <i>a.b.c.d</i> | Source IP address of the query packets. |
|--------------------|----------------|-----------------------------------------|

**Defaults** No source IP address is specified.

**Command Mode** Global configuration mode.

**Usage Guide**

After enabling IGMP querier, you also need to configure a source IP address for query packets, so that the device can send packets normally.

If no source IP address is specified in the VLAN needing to send packets, the device will verify whether the source IP address is specified globally. The device can only send query packets after finding the source IP configured, or else the querier function won't take effect.

If the IGMP querier source IP has been specified in VLAN, the source IP configured in the relevant VLAN will be used first.

**Configuration Examples** The following example specifies the source IP of query packets on the device:

```
Ruijie(config)# ip igmp snooping querier address 1.1.1.1
```

| Related Commands | Command                                      | Description                         |
|------------------|----------------------------------------------|-------------------------------------|
|                  | <b>ip igmp snooping vlan querier address</b> | Enables the source IP check in VLAN |

**Platform Description** N/A

## 9.18 ip igmp snooping querier max-response-time

To configure the maximum response time advertised in query packets, execute the global configuration command of "**ip igmp snooping querier max-response-time**". Use **no** form of this command to restore to the default value.

**ip igmp snooping querier max-response-time** *num*

**no ip igmp snooping querier max-response-time**

| Parameter Description | Parameter  | Description                                             |
|-----------------------|------------|---------------------------------------------------------|
|                       | <i>num</i> | Maximum response time (1-25); unit: second; default: 10 |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide**

Configure this command to specify the maximum response time to query packets.

By default, the maximum response time is 10 seconds. If the maximum response time has been

specified in the corresponding VLAN, the value specified in VLAN will be used first.

**Configuration** The following example specifies the maximum response time to query packets on the device:

**Examples** Ruijie(config)# ip igmp snooping querier max-response-time 15

| Related<br>Commands | Command                                                          | Description                                                   |
|---------------------|------------------------------------------------------------------|---------------------------------------------------------------|
|                     | <b>ip igmp snooping vlan querier</b><br><i>max-response-time</i> | Configures the maximum response time to query packets in VLAN |

**Platform** N/A

**Description**

## 9.19 ip igmp snooping querier query-interval

To specify the interval for IGMP querier to send query packets, execute the global configuration command of "**ip igmp snooping querier query-interval**". Use **no** form of this command to restore the query interval to the default value.

**ip igmp snooping querier query-interval** *num*

**no ip igmp snooping querier query-interval**

| Parameter          | Parameter  | Description                                                 |
|--------------------|------------|-------------------------------------------------------------|
| <b>Description</b> | <i>num</i> | Query interval (1-18000); unit: second; default: 60 seconds |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** After globally enabling IGMP querier, the timer will be enabled for sending query packets periodically. The aging time of the timer is the query interval. Configure this command to change the query interval.

If the query interval has been configured in the corresponding VLAN, the value specified in VLAN will be used first.

**Configuration** The following example configures the query interval on the device:

**Examples** Ruijie(config)# ip igmp snooping querier query-interval 100

| Related<br>Commands | Command                                             | Description                           |
|---------------------|-----------------------------------------------------|---------------------------------------|
|                     | <b>ip igmp snooping vlan querier query-interval</b> | Configures the query interval in VLAN |

**Platform** N/A

**Description**

## 9.20 ip igmp snooping querier timer expiry

To specify the expiration timer for non-querier, execute the global configuration command of "**ip igmp snooping querier timer expiry**". Use **no** form of this command to restore to the default value.

**ip igmp snooping querier timer expiry** *num*

**no ip igmp snooping querier timer expiry**

| Parameter   | Parameter  | Description                                                               |
|-------------|------------|---------------------------------------------------------------------------|
| Description | <i>num</i> | Non-querier expiration timer (60-300); unit: second; default: 125 seconds |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** After globally enabling IGMP querier, if the device is elected as a non-querier, execute this command to change the expiration timer for non-querier.

If expiration timer has been configured in the corresponding VLAN, the value specified in VLAN will be used first.

**Configuration Examples** The following example configures the non-querier expiration timer on the device:

```
Ruijie(config)# ip igmp snooping querier timer expiry 60
```

| Related Commands | Command                                           | Description                                 |
|------------------|---------------------------------------------------|---------------------------------------------|
|                  | <b>ip igmp snooping vlan querier timer expiry</b> | Configures querier expiration timer in VLAN |

**Platform Description** N/A

## 9.21 ip igmp snooping querier version

Use the following commands to specify IGMP Snooping querier version.

**ip igmp snooping [ vlan *vid* ] querier version 1**

**ip igmp snooping [ vlan *vid* ] querier version 2**

**ip igmp snooping [ vlan *vid* ] querier version 3**

Use **no** or **default** form of this command to restore to the default setting.

**no ip igmp snooping [ vlan *vid* ] querier version**

**default ip igmp snooping [ vlan *vid* ] querier version**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                        |                                                                                                                                       |             |                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------|-------------|-----------------------------------------------------------------------|
| Description            | vlan <i>vid</i>                                                                                                                       |             | VLAN ID. By default, the specified version is supported on all VLANs. |
| Default                | The default version is IGMPv2.                                                                                                        |             |                                                                       |
| Command Mode           | Global configuration mode                                                                                                             |             |                                                                       |
| Usage Guide            | If an IGMP querier version has been configured in a VLAN, the version specified in the VLAN will be used first.                       |             |                                                                       |
| Configuration Examples | The following example configures IGMP querier version on the device.<br><pre>Ruijie(config)# ip igmp snooping querier version 1</pre> |             |                                                                       |

## 9.22 ip igmp snooping query-max-response-time

This command specifies the time for the switch to wait for the member join message after receiving the **query** message. If the switch does not receive the member join message within the specified time, it considers that the member has left and then deletes the member.

**ip igmp snooping query-max-response-time** *time*

**no ip igmp snooping query-max-resposne-time**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                             |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <b>Parameter</b>    | <b>Parameter</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <b>Description</b>                                                          |
| <b>Description</b>  | <i>time</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | The aging time of the routing interface that the switch learns dynamically. |
| <b>Defaults</b>     | 10s                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                             |
| <b>Command Mode</b> | Global configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                             |
| <b>Usage Guide</b>  | <p>You can specify the time for the switch to wait for the member join message after receiving the query message. If the switch does not receive the member join message in the specified time, it considers that the member has left and then deletes the member. This command lets you adjust the waiting time after receiving the query message. This command takes effect only after the switch receives the next member join message. This command does not change the current wait time.</p> |                                                                             |

**Configuration** Set the aging time of the routing interface that the switch learns dynamically to 100s.

**Examples** Ruijie(config)# ip igmp snooping query-max-response-time 100

| Related<br>Commands | Command          | Function                                  |
|---------------------|------------------|-------------------------------------------|
|                     | ip igmp snooping | Configures a multicast routing interface. |

## 9.23 ip igmp snooping source-check default-server

The source IP address check is used to permit one or several IPMC flows from the server of the specified IP address.

To configure the source IP address check function of IGMP snooping, execute the **ip igmp snooping source-check default-server** command in the global configuration mode. The **no** form of this command is used to disable the source IP address check function.

**ip igmp snooping source-check default-server** *address*

**no ip igmp snooping source-check**

| Parameter<br>Description | Parameter      | Description                                                                      |
|--------------------------|----------------|----------------------------------------------------------------------------------|
|                          | <i>address</i> | Default multicast source IP address (IP address of the default multicast server) |

**Defaults** Disabled.

**Command**

**Mode** Global configuration mode.

**Usage Guide** The source IP address check function takes effect globally. Once it is enabled, only the IPMC streams from the specified IP address are permitted. The device allows users to configure the source IP address of all IPMC streams, called default multicast server. The default server must be set as long as the source IP address check function is enabled.

**Configuration Examples** The following example enables the multicast source IP address check function and configure a default source IP address.

```
Ruijie(config)# ip igmp snooping source-check default-server 192.168.4.243
```

| Related<br>Commands | Command                                 | Description                                 |
|---------------------|-----------------------------------------|---------------------------------------------|
|                     | ip igmp snooping limit-ipmc vlan server | Adds an entry to the source IP check table. |

## 9.24 ip igmp snooping source-check port

The source port check function is used to permit one or several IPMC flows from the mroute port.

To configure the source port check function of IGMP snooping, execute the **ip igmp snooping source-check port** command in the global configuration mode. The **no** form of this command is used to disable the source port check function.

**ip igmp snooping source-check port**  
**no ip igmp snooping source-check port**

**Parameter**

**Description** N/A.

**Defaults** Disabled.

**Command**

**Mode** Global configuration mode.

**Usage Guide** The source port check function takes effect globally. Once it is enabled, only the IPMC streams from the specified port are permitted.

**Configuration** The following example enables the source port check function of IGMP snooping.

**Examples** Ruijie(config)# ip igmp snooping source-check port

**Related  
Commands**

| Command                                             | Description                                             |
|-----------------------------------------------------|---------------------------------------------------------|
| <b>ip igmp snooping source-check default-server</b> | Enables the multicast source IP address check function. |

## 9.25 ip igmp snooping suppression enable

To enable IGMP snooping suppression, execute the **ip igmp snooping suppression enable** command in the global configuration mode. The **no** form of this command is used to disable IGMP snooping suppression..

**ip igmp snooping suppression enable**  
**no ip igmp snooping suppression enable**

**Parameter**

**Description** N/A

**Defaults** Disabled

**Command**

**Mode** Global configuration mode.

**Usage Guide** After you execute this command to enable the suppression function, the switch begins to suppress the IGMP v1/v2 report messages.

**Configuration** The following example enables IGMP snooping suppression on the device:

**Examples** Ruijie(config)# ip igmp snooping suppression

**Related  
Commands**      N/A

## 9.26 ip igmp snooping svgl profile

To specify the multicast group address range applied in the SVGL/IVGL-SVGL mode, execute the **ip igmp snooping profile** *profile-number* command in the global configuration mode. Use the **no ip igmp snooping profile** command to cancel the association.

**ip igmp snooping profile** *profile-number*

**no ip igmp snooping profile**

| Parameter   | Parameter             | Description                              |
|-------------|-----------------------|------------------------------------------|
| Description | <i>profile-number</i> | Profile number, in the range of 1-65535. |

**Default**      No profile is associated.

**Command**

**Mode**      Global configuration mode.

**Usage Guide**      When the IGMP Snooping works in the SVGL or IVGL-SVGL mode, a profile shall be associated to specify the multicast group address range applied in the SVGL or IVGL-SVGL mode. That is to say, the member ports of the multicast forwarding entry can be forwarded across the VLANs while the member ports of the multicast forwarding entry in the other multicast address range must belong to the same VLAN. By default, no profile is associated.

**Configuration**

**Examples**      Ruijie(config)# ip igmp snooping svgl profile 1

| Related<br>Commands | Command                           | Description                                      |
|---------------------|-----------------------------------|--------------------------------------------------|
|                     | <b>ip igmp snooping ivgl</b>      | Enables igmp snooping and enter the IVGL mode.   |
|                     | <b>ip igmp snooping ivgl-svgl</b> | Enables igmp snooping and enter the hybrid mode. |

## 9.27 ip igmp snooping svgl subvlan

To specify the subvlan of multicast VLAN, execute the global configuration command of "**ip igmp snooping svgl subvlan**". Use **no** form of this command to remove this configuration.

**ip igmp snooping svgl subvlan** [*vid-range*]

**no ip igmp snooping svgl subvlan** [*vid-range*]

| Parameter   | Parameter        | Description                 |
|-------------|------------------|-----------------------------|
| Description | <i>vid-range</i> | VLAN ID or range of VLAN ID |

**Defaults** By default, no subvlan is specified for svgl, and all VLANs serve as its subvlans.

**Command Mode** Global configuration mode.

**Usage Guide** This command only takes effect in SVGL or IVGL-SVGL mode.

**Configuration Examples** The following example configures the device operating in igmp snooping svgl mode to associate VLAN 2, 5, 6 and 7:

```
Ruijie(config)# ip igmp snooping svgl vlan 2,5-7
```

| Related Commands | Command                           | Description                                                 |
|------------------|-----------------------------------|-------------------------------------------------------------|
|                  | <b>ip igmp snooping svgl</b>      | Enables the igmp snooping and configure the svgl mode.      |
|                  | <b>ip igmp snooping ivgl-svgl</b> | Enables the igmp snooping and configure the IVGL-SVGL mode. |
|                  | <b>ip igmp snooping svgl vlan</b> | Configures the primary VLAN of SVGL mode.                   |

**Platform Description** N/A

## 9.28 ip igmp snooping svgl vlan

To specify the vlan as the shared vlan in the SVGL mode, execute the **ip igmp snooping svgl vlan** command in the global configuration mode. The **no** form of this command restores the Shared VLAN to vlan 1..

**ip igmp snooping svgl vlan** *vid*

**no ip igmp snooping svgl vlan**

| Parameter   | Parameter  | Description |
|-------------|------------|-------------|
| Description | <i>vid</i> | VLAN ID.    |

**Defaults** By default , the shared vlan is vlan1.

**Command Mode** Global configuration mode.

**Usage Guide** This command only works in the SVGL or IVGL-SVGL mode.

**Configuration** The following example specifies the vlan2 as the shared vlan

**Examples**

```
Ruijie(config)# ip igmp snooping svgl vlan 2
```

**Related  
Commands**

| Command                    | Description                                    |
|----------------------------|------------------------------------------------|
| ip igmp snooping svgl      | Enable igmp snooping and enter the SVGL mode.  |
| ip igmp snooping ivgl-svgl | Enable igmp snooping and enter the hybrid mode |

## 9.29 ip igmp snooping tunnel

Configure the relationship between IGMP Snooping and QinQ:

**ip igmp snooping tunnel**

**no ip igmp snooping tunnel**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

IGMP Passthrough is disabled.

**Command  
Mode**

Global configuration mode.

After IGMP Snooping is enabled and dot1q-tunnel port is configured on the device, IGMP packets received from dot1q-tunnel port will be handled in two ways through IGMP Snooping:

- 1st way: Create multicast entries in the VLAN to which the IMGP packets belong, and forward IMGP packets in such VLAN.

For example: It is assumed that IGMP Snooping has been enabled on the device; port A is a dot1q-tunnel port; the default VLAN of port A is VLAN 1, and packets from VLAN 1 and VLAN 10 can pass through port A. When multicast requests of VLAN 10 are sent to port A, IGMP Snooping will create the multicast entry of VLAN 10 and forward the multicast requests to the router port of VLAN 10.

**Usage Guide**

- 2nd way: Create multicast entries in the default VLAN to which the dot1q-tunnel ports belong, and forward multicast packets in the default VLAN of dot1q-tunnel port after inserting the VLAN Tag of the default VLAN of dot1q-tunnel port.

For example: It is assumed that IGMP Snooping has been enabled on the device; port A is a dot1q-tunnel port; the default VLAN of port A is VLAN 1, and packets from VLAN 1 and VLAN 10 can pass through port A. When multicast requests of VLAN 10 are sent to port A, IGMP Snooping will create the multicast entry of VLAN 1 and insert the VLAN Tag of VLAN 1 into multicast requests before forwarding the multicast requests to the router port of VLAN 1.

By default, the 2nd way is used.

**Configuration**

The following example enables the IGMP packets transparent transmission on the device:

**Examples**

```
Ruijie(config)# ip igmp snooping tunnel
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform** N/A

**Description**

## 9.30 ip igmp snooping vlan

Use this command to enable the igmp snooping on the specified vlan and enter the ivgl mode.

The **no** form of this command is used to disable the igmp snooping.

**ip igmp snooping vlan** *vid*

**no ip igmp snooping vlan** *vid*

| Parameter          | Parameter  | Description |
|--------------------|------------|-------------|
| <b>Description</b> | <i>vid</i> | VLAN ID     |

**Defaults** Disabled

**Command**

**Mode** Global configuration mode.

Use this command to enable or disable the IGMP snooping on the specified vlan.

**Usage  
Guide**

 The pim snooping on the specified vlan works only when the igmp snooping configured. When disabling the igmp snooping on the vlan with the pim snooping configured, it prompts to disable the pim snooping first and this execution fails.

**Configuration** The following example enables the igmp snooping on the vlan2.

**Examples** Ruijie(config)# ip igmp snooping vlan 2

| Related<br>Commands | Command                           | Description                                             |
|---------------------|-----------------------------------|---------------------------------------------------------|
|                     | <b>ip igmp snooping ivgl</b>      | Enables the igmp and enter the ivgl mode.               |
|                     | <b>ip igmp snooping ivgl-svgl</b> | Enables the igmp snooping and enter the ivgl-svgl mode. |

## 9.31 ip igmp snooping vlan mrouter interface

Routing interface is a port through which a multicast device is directly connected to a multicast neighbouring device. To configure a multicast routing interface, execute the **ip igmp snooping vlan mrouter interface** command in the global configuration mode. The **no** form of this command is used to delete a routing interface.

**ip igmp snooping vlan** *vid* **mrouter interface** *interface-id*

**no ip igmp snooping vlan** *vid* **mrouter interface** *interface-id*

|                          | Parameter           | Description                    |
|--------------------------|---------------------|--------------------------------|
|                          | <i>vid</i>          | VLAN ID of a routing interface |
| Parameter<br>Description | <i>interface-id</i> | Interface ID                   |

**Defaults** N/A

**Command**

**Mode** Global configuration mode

**Usage Guide** When the source port check function is enabled, only the multicast flows from the routing interface are forwarded, and other flows will be discarded.

**Configuration** The following example demonstrates how to configure a multicast routing interface on the equipment:

**Examples** Ruijie(config)# ip igmp snooping vlan 1 mrout erinterface fastEthernet 0/1

|  | Command                                   | Description                                       |
|--|-------------------------------------------|---------------------------------------------------|
|  | <b>ip igmp snooping source-check port</b> | Enables the multicast source port check function. |

## 9.32 ip igmp snooping vlan static interface

Once IGMP snooping is enabled, a port can receive a certain multicast frame without being affected by various IGMP messages by executing the **ip igmp snooping vlan static interface** command in the global configuration mode. The **no** form of this command is used to delete a static configuration.

**ip igmp snooping vlan** *vid* **static ip-addr interface** *interface-id*

**no ip igmp snooping vlan** *vid* **static ip-addr interface** *interface-id*

|                          | Parameter           | Description                    |
|--------------------------|---------------------|--------------------------------|
|                          | <i>vid</i>          | VLAN ID of a routing interface |
| Parameter<br>Description | <i>ip-addr</i>      | Multicast IP address           |
|                          | <i>interface-id</i> | Interface ID                   |

**Defaults** N/A

**Command**

**Mode** Global configuration mode

**Usage Guide** Multiple multicast IP addresses can be configured for an interface.

**Configuration** The following example demonstrates how to configure a static multicast address on a port:

**Examples**

```
Ruijie(config)# ip igmp snooping vlan 1 static 224.1.1.1 interface
GigabitEthernet 0/1
```

**Related****Commands**

| Command                                        | Description                              |
|------------------------------------------------|------------------------------------------|
| <b>ip igmp snooping vlan mdevice interface</b> | Configures a multicast routing interface |

## 9.33 permit

To permit the forwarding of the multicast streams in the range specified by the profile, execute the **permit** command in the profile configuration mode. In this way, the interface associated with this profile will forward the specified multicast stream only.

**Permit****Parameter**

**Description** N/A

**Defaults**

The forwarding of the multicast streams in the range specified by the profile is denied.

**Command****Mode**

Profile configuration mode

**Usage Guide**

First, configure the multicast range using the range command in the profile configuration mode. In addition, the profile must be applied to the interface in order to make the profile configuration to take effective.

**Configuration****Examples**

The following is an example of allowing the forwarding of the multicast stream 224.2.2.2:

```
Ruijie(config)# ip igmp profile 1
Ruijie(config-profile)# range 224.2.2.2
Ruijie(config-profile)# permit
```

**Related****Commands**

| Command                | Description                             |
|------------------------|-----------------------------------------|
| <b>ip igmp profile</b> | Creates a profile.                      |
| <b>range</b>           | Configures the multicast address range. |

## 9.34 range

To specify the range of multicast streams, execute the **range** command in the profile configuration mode. You can specify either a single multicast address or a range of multicast addresses. Use the **no** form of the command to remove the specified multicast IP address.

**range** *low-ip-address* [*high-ip-address*]

**no range** *low-ip-address* [*high-ip-address*]

| <b>Parameter</b><br><b>Description</b>  | Parameter                                                                                                                                                                                                                  | Description                                                                            |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
|                                         | <i>low-ip-address</i>                                                                                                                                                                                                      | Start address of a range                                                               |
|                                         | <i>high-ip-address</i>                                                                                                                                                                                                     | End address of a range                                                                 |
| <b>Defaults</b>                         | N/A                                                                                                                                                                                                                        |                                                                                        |
| <b>Command</b><br><b>Mode</b>           | Profile configuration mode                                                                                                                                                                                                 |                                                                                        |
| <b>Usage Guide</b>                      | You can specify a behavior after configuring the address range, for example deny by default. In addition, the profile must be applied to the interface in order to make the profile configuration take effect.             |                                                                                        |
| <b>Configuration</b><br><b>Examples</b> | <p>The following is an example of creating a profile whose multicast stream is in the range 224.2.2.2 to 224.2.2.244:</p> <pre>Ruijie(config)# ip igmp profile 1 Ruijie(config-profile)# range 224.2.2.2 224.2.2.244</pre> |                                                                                        |

|                                         | <b>ip igmp profile</b>                                                                                                                                                                                                     | Creates a profile.                                                                     |
|                                         | <b>deny</b>                                                                                                                                                                                                                | Denies the forwarding of the multicast streams in the range specified by the profile.  |
|                                         | <b>permit</b>                                                                                                                                                                                                              | Permits the forwarding of the multicast streams in the range specified by the profile. |

## 9.35 show ip igmp profile

Use this command to show the profile information.

**show ip igmp profile**

**show ip igmp profile** *profile-number*

| <b>Parameter</b><br><b>Description</b>  | Parameter                                                           | Description                                                   |
|-----------------------------------------|---------------------------------------------------------------------|---------------------------------------------------------------|
|                                         | <i>none</i>                                                         | Displays configuration information of all profiles.           |
|                                         | <i>profile-number</i>                                               | Displays configuration information of the designated profile. |
| <b>Command</b><br><b>Mode</b>           | Privileged EXEC mode                                                |                                                               |
| <b>Configuration</b><br><b>Examples</b> | <pre>Ruijie(config-if)# show ip igmp profile Profile 1 Permit</pre> |                                                               |

```
range 224.0.1.0, 239.255.255.255
```

## 9.36 show ip igmp snooping

Use this command to show related information of igmp snooping.

**show ip igmp snooping** [**gda-table** | **interfaces** *interface-type interface-number* | **mdevice** | **statistics** [**vlan** *vlan-id*] | **querier** [**detail** | **vlan** *vid*] | **user-info** ]

|                          | Parameter                              | Description                                                                |
|--------------------------|----------------------------------------|----------------------------------------------------------------------------|
| Parameter<br>Description | <b>vlan</b> <i>vid</i>                 | VLAN ID. By default, IGMP Snooping information of all VLANs are displayed. |
|                          | <i>interface-type interface-number</i> | Interface type and number                                                  |

**Command Mode**  
Privileged EXEC mode

The following example displays global IGMP Snooping information.

**Configuration Examples**

```
Ruijie#show ip igmp snooping
IGMP Snooping running mode: IVGL
IGMP Snooping L2-entry-limit: 65536
Source port check: Disable
Source ip check: Disable
IGMP Fast-Leave: Disable
IGMP Report suppress: Disable
IGMP Globle Querier: Disable
IGMP Preview: Disable
IGMP Tunnel: Disable
IGMP Snooping version: 2IGMP Preview group aging time : 60(Seconds)
Dynamic Mroute Aging Time : 300(Seconds)
Dynamic Host Aging Time : 260(Seconds)
The following example displays VLAN1 IGMP Snooping information.Ruijie#show
ip igmp snooping vlan 1
IGMP Snooping running mode: IVGL
IGMP Snooping L2-entry-limit: 65536
Global IGMPv2 Fast-Leave :Disable
Global multicast router learning mode :Enable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time : 300(Seconds)
Dynamic Host Aging Time : 260(Seconds)

vlan 1
-----
```

```
IGMP Snooping state: Enable
Multicast router learning mode: pim-dvmrp
IGMP Fast-Leave: Disable
IGMP VLAN querier: Disable
IGMP VLAN Mode: STATIC
```

## 10 MLD Snooping Commands

### 10.1 clear ipv6 mld snooping gda-table

Use this command to clear the forwarding table information learned dynamically.

**clear ipv6 mld snooping gda-table**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear the forwarding table information learned dynamically.

**Configuration Examples** The following example clears the forwarding table information learned dynamically:

```
Ruijie# clear ipv6 mld snooping gda-table
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform Description** N/A

### 10.2 clear ipv6 mld snooping statistics

Use this command to clear the MLD Snooping statistics, including the entry number, the entry volume, the number of various received packets, the group information and the interface information of the corresponding group.

**clear ipv6 mld snooping statistics**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** Use the **show ipv6 mld snooping statistics** command to verify the configuration.

**Configuration** The following example clears the MLD Snooping statistics.

**Examples** Ruijie# clear ipv6 mld snooping statistics

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform** N/A

**Description**

## 10.3 deny

Use this command to prevent the multicast flow profile within the specified range from being forwarded in the profile configuration mode.

**deny****Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The default profile action is **deny**.

**Command** Profile configuration mode  
**Mode**

**Usage Guide** Before configuring this command, use the **range** command to set the multicast range first.

**Configuration** The following example prevents the multicast flow profile within the range of FF77::100 from being forwarded.

**Examples**

```
Ruijie(config)# ipv6 mld profile 1
Ruijie(config-profile)# range FF77::100
Ruijie(config-profile)# deny
```

**Related  
Commands**

| Command                 | Description                       |
|-------------------------|-----------------------------------|
| <b>ipv6 mld profile</b> | Creates one profile.              |
| <b>range</b>            | Sets the multicast address range. |
| <b>permit</b>           | Sets the profile action permit.   |

**Platform** N/A

**Description**

## 10.4 ipv6 mld profile

Use the following command to create a profile. Use the **no** or **default** form of this command to delete a profile.

**ipv6 mld profile** *profile-number*

**no ipv6 mld profile** *profile-number*

**default ipv6 mld profile** *profile-number*

| Parameter<br>Description | Parameter      | Description                                  |
|--------------------------|----------------|----------------------------------------------|
|                          | profile-number | Profile number, in the range from 1 to 1024. |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** Profile is a kind of group “filter” that can be referred to by other functions.

Configuration Steps:

1. Use the **ipv6mld profile** command to create a profile and enter the profile mode.
2. Use the **range** command to define a group.
3. Use the **permit** command to allow this group to pass the filtering; Use the **deny** command to filter the packets of this group. The default command is **deny**.

**Configuration Examples** The following example creates profile 1 and allows the packets sent by devices with MAC address ranging from FF15::1 to FF15::100 to pass the filtering.

```
Ruijie(config)#ipv6 mld profile 1
Ruijie(config-profile)#range FF15::1 FF15::100
Ruijie(config-profile)#permit
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform** N/A

**Description**

## 10.5 ipv6 mld snooping

Use this command to enable MLD Snooping and specify IVGL/SVGL/IVGL-SVGL mode. Use the **no**

or **default** form of this command to restore the default setting.

**ipv6 mld snooping {ivgl | svgl | ivgl-svgl}**

**no ipv6 mld snooping [ivgl | svgl | ivgl-svgl]**

**default ipv6 mld snooping [ivgl | svgl | ivgl-svgl]**

**Parameter  
Description**

| Parameter        | Description                             |
|------------------|-----------------------------------------|
| <b>ivgl</b>      | MLD Snooping is running IVGL mode.      |
| <b>svgl</b>      | MLD Snooping is running SVGL mode.      |
| <b>ivgl-svgl</b> | MLD Snooping is running IVGL-SVGL mode. |

**Defaults**

This function is disabled by default.

**Command  
Mode**

Global configuration mode

**Usage Guide**

- In IVGL mode, multicast flow in each VLAN is independent. The host only requests multicast flow from the routing interface within the same VLAN. The device forwards the multicast flow from any VLAN to the member port within the same VLAN.
- In SVGL mode, multicast flow is shared among VLANs. The host can request multicast flow across VLANs. Shared VLAN (VLAN 1 by default) should be specified. Only multicast flow from Shared VLAN can be forwarded to all member ports within the group address range, which may belong to different VLANs. Profile is used to specify a group range for SVGL. Only multicast flow within this range can be forwarded across VLANs. The other multicast flow is discarded.
- In IVGL-SVGL mode, Profile is used to specify a group range for SVGL. Multicast flow within this range is in SVGL mode and the other multicast flow is in IVGL mode.

**Configuration** The following example enables MLD Snooping IVGL mode.

**Examples**

```
Ruijie(config)# ip igmp snooping ivgl
```

The following example enables MLD Snooping SVGL mode and specifies the shared VLAN and SVGL group range as VLAN1 and profile1 respectively.

```
Ruijie(config)# ip igmp snooping svgl
```

```
Ruijie(config)# ip igmp snooping svgl profile 1
```

## 10.6 ipv6 mld snooping dyn-mr-aging-time

Use this command to set the aging time of the dynamic multicast route port. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping dyn-mr-aging-time** *time*

**no ipv6 mld snooping dyn-mr-aging-time**

**default ipv6 mld snooping dyn-mr-aging-time**

### Parameter Description

| Parameter | Description                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------|
| time      | Sets the aging time of the dynamic multicast route port, in the range from 1 to 3600 in the unit of seconds. |

**Defaults** The default is 300.

**Command Mode** Global configuration mode.

**Usage Guide** The switch will remove the dynamic multicast router interface from the router interface list if it fails to receive the MLD general group query packets or the Ipv6 PIM Hello packets within the aging timeout on this interface.

**Configuration Examples** The following example sets the aging time of the dynamic multicast route port to 500 seconds.

```
Ruijie(config)# ipv6 mld snooping dyn-mr-aging-time 500
```

## 10.7 ipv6 mld snooping fast-leave enable

Use this command to enable the MLD Snooping fast-leave in the global configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping fast-leave enable**

**no ipv6 mld snooping fast-leave enable**

**default ipv6 mld snooping fast-leave enable**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|     |     |
|-----|-----|
| N/A | N/A |
|-----|-----|

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode.

**Usage Guide** The interface fast leave is that when IPv6 MLD Leave packets sent from the host are received on an interface, the interface is removed from the outgoing interface list of the corresponding forwarding entry. Then, the switch will not forward the received IPv6 MLD specific group query packets to the interface. If there is only one receiver connected with the interface, enable the interface fast leave function to save the bandwidth and resources.

**Configuration** The following example enables mld snooping fast-leave.

**Examples** Ruijie(config-if)# ipv6 mld snooping fast-leave

## 10.8 ipv6 mld snooping filter

Use this command to filter the specific multicast flow in the interface configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping filter** *profile-number*

**no ipv6 mld snooping filter**

**default ipv6 mld snooping filter**

| Parameter Description | Parameter      | Description                                          |
|-----------------------|----------------|------------------------------------------------------|
|                       | profile-number | Sets the profile number in the range from 1 to 1024. |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** You can configure an MLD Profile on an interface. If the MLD Report packets are received on the interface, the layer-2 device will determine whether the multicast address to be joined the interface is within the allowed range of the MLD Profile. The specified profile must be created before using this command.

**Configuration** The following example associates profile1 with the interface fastEthernet 0/1.

**Examples**

```
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ipv6 mld snooping filter 1
```

**Related  
Commands**

| Command                 | Description        |
|-------------------------|--------------------|
| <b>ipv6 mld profile</b> | Creates a profile. |

**Platform** N/A

**Description**

## 10.9 ipv6 mld snooping host-aging-time

Use this command to set the aging time of the dynamic member port.

Use the **no** form of this command to cancel this configuration.

Use the **default** form of this command to restore the aging time to the default setting.

**ipv6 mld snooping host-aging-time** *seconds*

**no ipv6 mld snooping host-aging-time**

**default ipv6 mld snooping host-aging-time**

**Parameter  
Description**

| Parameter | Description                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------|
| seconds   | Sets the aging time of the dynamic member port, in seconds, ranging from 1-65536 in the unit of seconds. |

**Defaults** The default aging time of the dynamic member port is 260 seconds.

**Command  
Mode** Global configuration mode

**Usage Guide** The switch will remove the dynamic multicast router interface from the router interface list if it fails to receive the MLD general group query packets or the IPv6 PIM Hello packets within the aging timeout on this interface.

When the MLD Snooping is enabled, the port that receives the MLD Report packet will learn to be a dynamic member port. The default aging time of such dynamic member port is 260 seconds. You can use this command to adjust the aging time. This configuration takes effect after the port receives the the next Report packet. The aging time of the dynamic member port should be longer than the query interval.

**Configuration** The following example shows how to sets the aging time of the dynamic member port to 200 seconds:

**Examples**

```
Ruijie(config)# ipv6 mld snooping host-aging-time 200
```

Description

## 10.10 ipv6 mld snooping max-groups

Use this command to set the maximum group allowed to join the interface dynamically in the interface configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping max-groups** *number*

**no ipv6 mld snooping max-groups**

**default ipv6 mld snooping max-groups**

| Parameter<br>Description | Parameter | Description                                        |
|--------------------------|-----------|----------------------------------------------------|
|                          | number    | The number of groups, in the range from 0 to 65536 |

Defaults The default is 65536.

Command Interface configuration mode  
Mode

Usage Guide With this command configured, when the group number exceeds the specified range on the interface, the switch will not receive and deal with the MLD Report packets.

Configuration The following example sets the maximum 100 multicast group on the interface fastEthernet 0/1.

Examples

```
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ipv6 mld snooping max-group 100
```

| Related<br>Commands | Command                         | Description                                   |

Description

## 10.11 Ipv6 mld snooping mrouter learn

Use this command to enable the switch to dynamically learn MLD query or PIM packets to identify the mrouter interface automatically. Use the **no** form of this command to disable this function. Use the **default** form of this command to restore the default setting.

**ipv6 mld snooping [ vlan *vid* ] mrouter learn**

**no ipv6 mld snooping [ vlan *vid* ] mrouter learn**  
**default ipv6 mld snooping [ vlan *vid* ] mrouter learn**

**Parameter  
Description**

| Parameter       | Description                               |
|-----------------|-------------------------------------------|
| vlan <i>vid</i> | The vlan ID, in the range from 1 to 4094. |

**Defaults** This function is enabled by default.

**Command  
Mode** Global configuration mode

**Usage Guide** The mrouter interface is the interface of the multicast device connected with the peer device. By default, the dynamically-learned mroute interface is enabled on the layer-2 multicast device. Use the **no** option to disable this function and clear all dynamically-learned mroute interfaces.

- ✓ With the source port check enabled, only the multicast flow through the mroute interface are valid and forwarded to the registered interface on the layer-2 multicast device. Those multicast flow through the non-mroute interface are invalid and will be discarded.

**Configuration** The following example enables the dynamic multicast route port learn function for VLAN1.

**Examples**

```
Ruijie(config)# no ipv6 mld snooping mrouter learn
Ruijie(config)# ipv6 mld snooping vlan 1 mrouter learn
```

**Related  
Commands** N/A

## 10.12 ipv6 mld snooping query-max-response-time

Use this command to set the maximum response time of the MLD general query packet. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping query-max-response-time *seconds***  
**no ipv6 mld snooping query-max-response-time**  
**default ipv6 mld snooping query-max-response-time**

**Parameter  
Description**

| Parameter | Description                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------|
| seconds   | Sets the maximum response time of the MLD general query packet in the range from 1 to 65535 in the unit of seconds. |

**Defaults** The default is 10 seconds.

**Command  
Mode** Interface configuration mode

**Usage Guide** Upon receiving the MLD general query packets, the Layer-2 multicast device updates the aging timer of all member ports. The time of the timer is the longest response value. When the timer value decreases to 0, it indicates that there is no member receiving the multicast flow on the interface, and the Layer-2 device removes this interface from the MLD Snooping forwarding list.

Upon receiving the MLD specific group query packets, the Layer-2 multicast device enables the aging timer of all member ports in this specific group. The time of the timer is the longest response value. When the timer value decreases to 0, it indicates that there is no member receiving the multicast flow on the interface, and the Layer-2 device removes this interface from the MLD Snooping forwarding list.

For the source query packets of the MLD specific group, the timer is not updated.

The configured maximum response time

**Configuration Examples** The following example sets the maximum response time of the MLD general query packet to 15 seconds.

```
Ruijie(config)# ipv6 mld snooping query-max-response-time 15
```

## 10.13 ipv6 mld snooping source-check port

The source-check port is used to allow the multicast flow to enter through the mrouter interface. Use this command to enable the mld source-check port in the global configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping source-check port**

**no ipv6 mld snooping source-check port**

**default ipv6 mld snooping source-check port**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The source-check port is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** The MLD Snooping source port check function is to limit the MLD multicast flow through the interace strictly. With the source port check disabled, all video flow are illegal and forwarded to the registered

member port according to the MLD Snooping forwarding list. With the MLD Snooping source port check enabled, only the multicast flow through the mroute interface is legal and forwarded to the registered interface by the layer-2 multicast device; and the multicast flow through the non-mroute interface are illegal and discarded.

This command is used to enable the source port check globally. Once this function is enabled, all multicast flow must come from the mroute interface, or they'll be discarded.

**Configuration** The following example shows how to enable MLD Snooping source-check port:

**Examples** Ruijie(config-if)# ipv6 mld snooping source-check port

**Description**

## 10.14 ipv6 mld snooping suppression enable

Use this command to enable the MLD Snooping suppression in the global configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping suppression enable**

**no ipv6 mld snooping suppression enable**

**default ipv6 mld snooping suppression enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The MLD Snooping suppression function is disabled by default.

**Command  
Mode** Global configuration mode.

**Usage Guide** With the IPv6 MLD Snooping suppression function enabled, within the query interval, the layer-2 device will only forward the first received MLD Report packet in an IPv6 multicast group to the layer-3 device, but not the other MLD Report packets in the same IPv6 multicast group, reducing the packet number in the network.

This command is used to enable the IPv6 MLD Snooping suppression, and only the MLDv1 Report packets are suppressed rather than the MLDv2 Report packets.

**Configuration** The following example enables MLD Snooping suppression.

**Examples** Ruijie(config-if)# ipv6 mld snooping suppression

## 10.15 ipv6 mld snooping svgl profile

Use this command to specify the group address range to be in the SVGL mode. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping svgl profile** *profile-number*

**no ipv6 mld snooping svgl profile**

**default ipv6 mld snooping svgl profile**

| Parameter Description | Parameter      | Description                                           |
|-----------------------|----------------|-------------------------------------------------------|
|                       | profile-number | Sets the profile number, in the range from 1 to 1024. |

**Defaults** No profiles are associated with svgl by default.

**Command Mode** Global configuration mode

**Usage Guide** With the SVGL mode or IVGL-SVGL mode configured for the MLD Snooping working mode, a profile shall be associated with the IVGL for the purpose of specifying the group address range in the SVGL mode. That is to say, the member port of the multicast forwarding entry can be forwarded across the VLANs, while the member ports of the corresponding multicast forwarding entries within other multicast address range must belong to the same VLAN. By default, no profile is associated, which means that apply no multicast group in the SVGL mode.

**Configuration Examples** The following example specifies the SVGL mode application range as the profile1 group address range.

```
Ruijie(config)# ipv6 mld snooping svgl profile 1
```

| Related Commands | Command                            | Description                                          |

**Description**

## 10.16 ipv6 mld snooping svgl vlan

Use this command to specify the shared VLAN in MLD Snooping SVGL mode.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping svgl vlan** *vid*

**no ipv6 mld snooping svgl vlan**

**default ipv6 mld snooping svgl vlan**

**Parameter  
Description**

| Parameter  | Description                               |
|------------|-------------------------------------------|
| <i>vid</i> | The VLAN ID, in the range from 1 to 4094. |

**Defaults**

The default is 1.

**Command  
Mode**

Global configuration mode

**Usage Guide**

This command is used to specify the SVGL shared VLAN if MLD Snooping is running in SVGL or IVGL-SVGL mode.

**Configuration**

The following example sets the shared VLAN in MLD Snooping SVGL mode to 5.

**Examples**

```
Ruijie(config)# ipv6 mld snooping svgl vlan 5
```

## 10.17 ipv6 mld snooping vlan

Use this command to enable the MLD Snooping function for the specified VLAN. Use the **no** form of this command to disable this function. Use the default form of this command to restore the default setting.

**ipv6 mld snooping vlan** *vid*

**no ipv6 mld snooping vlan** *vid*

**default ipv6 mld snooping vlan** *vid*

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|     |                                           |
|-----|-------------------------------------------|
| vid | The VLAN ID, in the range from 1 to 4094. |
|-----|-------------------------------------------|

**Defaults** The MLD Snooping function is enabled by default.

**Command Mode** Global configuration mode

**Usage Guide** By default, the MLD Snooping is enabled in all VLANs. You can disable the MLD Snooping for the specified VLAN.

**Configuration** The following example disables the MLD Snooping function in vlan1:

**Examples** Ruijie(config)# no ipv6 mld snooping vlan 1

| Related Commands | Command | Description |

## 10.18 ipv6 mld snooping vlan mrouter interface

Use this command to set the static mrouter interface.

Use the **no** form of this command to restore the default setting.

**ipv6 mld snooping vlan** *vid mrouter interface interface-type interface-number*

**no ipv6 mld snooping vlan** *vid mrouter interface interface-type interface-number*

**default ipv6 mld snooping vlan** *vid mrouter interface interface-type interface-number*

| Parameter Description | Parameter        | Description                               |
|-----------------------|------------------|-------------------------------------------|
|                       | vid              | The VLAN ID, in the range from 1 to 4094. |
|                       | interface-type   | The interface number                      |
|                       | interface-number |                                           |

**Defaults** No static mrouter interface is configured by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to set the static mrouter interface for the purpose that all IPv6 multicast data received on the switch can be forwarded. With the source port check function enabled, only the multicast flow through the mroute interface can be forwarded.

**Configuration** The following example sets a multicast routing port:

**Examples**

```
Ruijie(config)# ipv6 mld snooping vlan 1 mrouter interface fastEthernet 0/1
```

**Related  
Commands**

**Description**

## 10.19 ipv6 mld snooping vlan mrouter learn

Use this command to enable the switch to dynamically learn MLD query or PIM packets to identify the mrouter interface automatically. Use the **no** form of this command to disable this function.

**ipv6 mld snooping vlan vid mrouter learn**

**no ipv6 mld snooping vlan vid mrouter learn**

**Parameter  
Description**

| Parameter | Description                                                 |
|-----------|-------------------------------------------------------------|
| vid       | The vlan id, in the range from 1 to 4094. The default is 1. |

**Defaults** This function is enabled by default.

**Command  
Mode** Global configuration mode.

**Usage Guide** The mrouter interface is the interface of the multicast device connected with the peer device. By default, the dynamically-learned mroute interface is enabled on the layer-2 multicast device. Use the **no** option to disable this function and clear all dynamically-learned mroute interfaces. With the source port check enabled, only the multicast flow through the mroute interface are valid and forwarded to the registered interface on the layer-2 multicast device. Those multicast flow through the non-mroute interface are invalid and will be discarded. With the source port check function enabled, use the dynamically-learned mroute interfaces to improve the mld snooping flexibility.

**Configuration** The following example enables the dynamic multicast route port learn function.

**Examples**

```
Ruijie(config)# ipv6 mld snooping vlan 1 mrouter learn
```

**Related  
Commands**

**Description**

## 10.20 ipv6 mld snooping vlan static interface

Use this command to set a static member port to receive the multicast flow for the purpose of preventing the port from being influenced by the MLD Report packets with the MLD Snooping enabled. Uses the **no** form of this command to restore the default setting.

**ipv6 mld snooping vlan** *vid* **static** *group-address* **interface** *interface-type* *interface-number*

**no ipv6 mld snooping vlan** *vid* **static** *group-address* **interface** *interface-type* *interface-number*

### Parameter Description

| Parameter                          | Description                                                 |
|------------------------------------|-------------------------------------------------------------|
| vid                                | The vlan id, in the range from 1 to 4094. The default is 1. |
| group-address                      | The multicast address                                       |
| interface-type<br>interface-number | The interface number                                        |

**Defaults** No static member port is configured by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to set the interface as the member port of multiple static multicast addresses.

**Configuration Examples** The following example sets the interface fastEthernet 0/1 as the static member port of the FF88::1 group.

```
Ruijie(config)# ipv6 mld snooping vlan 1 static FF88::1 interface fastEthernet 0/1
```

### Related Commands

## 10.21 permit

Use this command to allow the multicast flow profile within the specified range in the profile configuration mode.

**permit**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|     |     |
|-----|-----|
| N/A | N/A |
|-----|-----|

**Defaults** The default profile action is **deny**.

**Command Mode** Profile configuration mode

**Usage Guide** Before configuring this command, use the **range** command to set the multicast range first.

**Configuration Examples** The following example allows the multicast flow profile within the range of FF77::1 to be forwarded only:

```
Ruijie(config)# ipv6 mld profile 1
Ruijie(config-profile)# range FF77::1
Ruijie(config-profile)# permit
```

**Related Commands**

| Command                 | Description                       |

| <b>ipv6 mld profile</b> | Creates one profile.              |
| <b>range</b>            | Sets the multicast address range. |
| <b>deny</b>             | Sets the profile action deny.     |

**Platform Description** N/A

## 10.22 range

Use this command to specify the profile multicast flow range, which can be one single multicast address, or can be the multicast address within the specified range when configuring a profile in the profile configuration mode.

**range** *low-ipv6-address* [ *high-ip-address* ]

**Parameter Description**

| Parameter       | Description                                 |
|-----------------|---------------------------------------------|
| low-ip-address  | The low address within the specified range  |
| high-ip-address | The high address within the specified range |

**Defaults** No range is defined by default.

**Command Mode** Profile configuration mode

**Usage Guide** The value of low-ipv6-address shall be smaller than the one of high-ipv6-address. With the address range configured, an action shall be specified, and the default profile action is deny.

**Configuration** The following example creates the multicast flow profile within the range of FF77::1~FF77::100.

**Examples**

```
Ruijie(config)# ipv6 mld profile 1
Ruijie(config-profile)# range FF77::1 FF77::100
```

**Related  
Commands**

| Command                 | Description                     |
|-------------------------|---------------------------------|
| <b>ipv6 mld profile</b> | Creates one profile.            |
| <b>deny</b>             | Sets the profile action deny.   |
| <b>permit</b>           | Sets the profile action permit. |

**Platform** N/A

**Description**

## 10.23 show ipv6 mld profile

Use this command to display the related MLD profile configuration.

**show ipv6 mld profile** *profile-number*

**Parameter  
Description**

| Parameter      | Description                                          |
|----------------|------------------------------------------------------|
| profile-number | Displays the configuration of the specified profile. |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** Use this command to display the related MLD profile configuration.

**Configuration** The following example displays the MLD profile configuration.

**Examples**

```
Ruijie# show ipv6 mld profile 1
MLD Profile 1
permit
range FF77::1 FF77::100
range FF88::123
```

## 10.24 show ipv6 mld snooping

Use this command to display the related MLD Snooping information.

**show ipv6 mld snooping** [**gda-table** | **interfaces** *interface-type interface-number* | **mrouter** | **statistics**[*vlan vid*] | **vlan** *vid*]

### Parameter Description

| Parameter                                                | Description                                                  |
|----------------------------------------------------------|--------------------------------------------------------------|
| <b>gda-table</b>                                         | Displays the multicast forwarding rule table.                |
| <b>Interfaces</b> <i>interface-type interface-number</i> | Displays the MLD Snooping filtering configuration.           |
| <b>mrouter</b>                                           | Displays the information about mrouter interface.            |
| <b>statistics</b>                                        | Displays the MLD Snooping statistics.                        |
| <b>vlan</b> <i>vlan-id</i>                               | Displays the MLD Snooping information of the specified vlan. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** Use this command to display the related MLD Snooping information.

**Configuration Examples** The following example displays the MLD Snooping configurations using the **show ipv6 mld snooping** command:

```
Ruijie# show ipv6 mld snooping
MLD-snooping mode      : IVGL
SVGL vlan-id           : 1
SVGL profile number     : 0
Source check port       : Disabled
Query max response time : 10(Seconds)
```

The following example displays the mrouter interface of the MLD Snooping using the **show ipv6 mld snooping statistics** command:

```
Ruijie# show ipv6 mld snooping statistics
GROUP  Interface  Last report   Last leave    Last
                                time          time          reporter
-----
FF88::1 VL1:Gi4/2 0d:0h:0m:7s  ----        2003::1111
                                Report pkts: 1  Leave pkts: 0
```

The following example displays the mrouter interface of the MLD Snooping using the **show ipv6 mld snooping mrouter** command:

```
Ruijie# show ipv6 mld snooping mrouter
Vlan    Interface      State      MLD profile number
----    -
-----
```

```

1  GigabitEthernet 0/7    static      1
1  GigabitEthernet 0/12   dynamic    0

```

The following example displays the multicast group information in the GDA table and all member ports information of one multicast group:

```
Ruijie# show ipv6 mld snooping gda-table
```

Abbr: M - mrouter

D - dynamic

S - static

```

VLAN  Address                Member ports
-----
1      FF88::1                GigabitEthernet 0/7(S)

```

The following example displays the MLD Snooping filtering configuration using the **show ipv6 mld snooping mrouter** command:

```
Ruijie# show ipv6 mld snooping interface GigabitEthernet 0/7
```

```

Interface          Filter Profile number    max-groups
-----
GigabitEthernet 0/7          1                4294967294

```

# 1 AAA Commands

## 1.1 aaa accounting commands

Use this command to account users in order to enable NAS command accounting.

Use the **no** form of this command to restore the default setting.

**aaa accounting commands** *level* { **default** | *list-name* } **start-stop** *method1* [ *method2...*]

**no aaa accounting commands** *level* { **default** | *list-name* }

| Parameter   | Parameter        | Description                                                                                                           |
|-------------|------------------|-----------------------------------------------------------------------------------------------------------------------|
| Description | <i>level</i>     | The accounting command level, 0-15. The message shall be recorded before determining which command level is executed. |
|             | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for command accounting.  |
|             | <i>list-name</i> | Name of the command accounting method list, which could be any character strings.                                     |
|             | <i>method</i>    | It must be one of the keywords listed in the following table. One method list can contain up to four methods.         |
|             | <b>none</b>      | Does not perform accounting.                                                                                          |
|             | <b>group</b>     | Uses the server group for accounting, the TACACS+ server group is supported.                                          |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS enables the accounting command function after enabling the login authentication. After enabling the accounting function, it sends the command information to the security service.  
The configured accounting command method must be applied to the terminal line that needs accounting command; otherwise it is ineffective.

**Configuration** The following example enables NAS command accounting.

**Examples** Ruijie(config)# aaa accounting commands 15 default start-stop group tacacs+

| Related Commands | Command                    | Description                                           |
|------------------|----------------------------|-------------------------------------------------------|
|                  | <b>aaa new-model</b>       | Enables the AAA security service.                     |
|                  | <b>aaa authentication</b>  | Defines AAA authentication.                           |
|                  | <b>accounting commands</b> | Applies the accounting commands to the terminal line. |

**Platform** N/A

**Description**

## 1.2 aaa accounting exec

Use this command to enable NAS access accounting. Use the **no** form of this command to restore the default setting.

**aaa accounting exec** { **default** | *list-name* } **start-stop** *method1* [ *method2...*]

**no aaa accounting exec** { **default** | *list-name* }

| Parameter   | Parameter        | Description                                                                                                       |
|-------------|------------------|-------------------------------------------------------------------------------------------------------------------|
| Description | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for Exec accounting. |
|             | <i>list-name</i> | Name of the Exec accounting method list, which could be any character strings                                     |
|             | <i>method</i>    | It must be one of the keywords: <b>none</b> and <b>group</b> . One method list can contain up to four methods.    |
|             | <b>none</b>      | Does not perform accounting.                                                                                      |
|             | <b>group</b>     | Uses the server group for accounting, the RADIUS and TACACS+ server group is supported.                           |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** RGOS enables the exec accounting function after enabling the login authentication. After enabling the accounting function, it sends the account start information to the security server when the users log in the NAS CLI, and sends the account stop information to the security server when the users log out. If it does not send the account start information to the security server when a user logs in, it does not send the account stop information to the security server when a user logs out, either. The configured exec accounting method must be applied to the terminal line that needs accounting command; otherwise it is ineffective.

**Configuration** The following example enables NAS access accounting.

**Examples** Ruijie(config)# aaa accounting network start-stop group radius

| Related  | Command                    | Description                                       |
|----------|----------------------------|---------------------------------------------------|
| Commands | <b>aaa new-model</b>       | Enables the AAA security service.                 |
|          | <b>aaa authentication</b>  | Defines AAA authentication.                       |
|          | <b>accounting commands</b> | Applies the Exec accounting to the terminal line. |

**Platform** N/A

**Description**

## 1.3 aaa accounting network

Use this command to enable network access accounting. Use the **no** form of this command to restore the default setting.

**aaa accounting network { default | list-name } start-stop method1 [ method2..]**

**no aaa accounting network { default | list-name }**

| Parameter   | Parameter        | Description                                                                                                                                                                                               |
|-------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for Network accounting.                                                                                      |
|             | <i>list-name</i> | Name of the accounting method list                                                                                                                                                                        |
|             | <i>method</i>    | Sends accounting messages at both the start time and the end time of access. Users are allowed to access the network, no matter whether the start accounting message enables the accounting successfully. |
|             | <b>none</b>      | Does not perform accounting.                                                                                                                                                                              |
|             | <b>group</b>     | Uses the server group for accounting, the RADIUS and TACACS+ server group is supported.                                                                                                                   |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS performs accounting of user activities by sending record attributes to the security server. Use the **start-stop** keyword to set the user accounting option.

**Configuration Examples** The following example enables network access accounting.

```
Ruijie(config)# aaa accounting network start-stop group radius
```

| Related Commands | Command                          | Description                                  |
|------------------|----------------------------------|----------------------------------------------|
|                  | <b>aaa new-model</b>             | Enables the AAA security service.            |
|                  | <b>aaa authorization network</b> | Defines a network authorization method list. |
|                  | <b>aaa authentication</b>        | Defines AAA authentication.                  |
|                  | <b>username</b>                  | Defines a local user database.               |

**Platform** N/A

**Description**

## 1.4 aaa accounting update

Use this command to enable the accounting update function. Use the **no** form of this command to restore the default setting.

**aaa accounting update**  
**no aaa accounting update**

**Parameter**  
**Description**

N/A

**Defaults**

This function is disabled by default.

**Command**  
**Mode**

Global configuration mode

**Usage Guide**

If the AAA security service is not enabled, the accounting update function cannot be used. This command is used to set the accounting interval if the AAA security service has been enabled.

**Configuration**

The following example enables the accounting update function.

**Examples**

```
Ruijie(config)# aaa new-model  
Ruijie(config)# aaa accounting update
```

**Related**  
**Commands**

| Command                       | Description                               |
|-------------------------------|-------------------------------------------|
| <b>aaa new-model</b>          | Enables the AAA security service.         |
| <b>aaa accounting network</b> | Defines a network accounting method list. |

**Platform**  
**Description**

N/A

## 1.5 aaa accounting update periodic

If the accounting update function has been enabled, use this command to set the interval of sending the accounting update message. Use the **no** form of this command to restore the default setting.

**aaa accounting update periodic** *interval*  
**no aaa accounting update periodic**

**Parameter**  
**Description**

| Parameter       | Description                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------------------|
| <i>interval</i> | Interval of sending the accounting update message, in the unit of minutes. The shortest interval is 1 minute. |

**Defaults**

The default is 5 minutes.

**Command**  
**Mode**

Global configuration mode

**Usage Guide**

If the AAA security service is not enabled, the accounting update function cannot be used. This command is used to set the accounting interval if the AAA security service has been enabled.

**Configuration** The following example sets the interval of accounting update to 1 minute.

**Examples**

```
Ruijie(config)# aaa new-model
Ruijie(config)# aaa accounting update
Ruijie(config)# aaa accounting update periodic 1
```

| Related<br>Commands | Command                       | Description                               |
|---------------------|-------------------------------|-------------------------------------------|
|                     | <b>aaa new-model</b>          | Enables the AAA security service.         |
|                     | <b>aaa accounting network</b> | Defines a network accounting method list. |

**Platform** N/A

**Description**

## 1.6 aaa authentication enable

Use this command to enable AAA Enable authentication and configure the Enable authentication method list. Use the **no** form of this command to delete the user authentication method list.

**aaa authentication enable { default | list-name } method1 [ method2..]**

**no aaa authentication enable default**

| Parameter<br>Description | Parameter      | Description                                                                                                                            |
|--------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------|
|                          | <b>default</b> | When this parameter is used, the following defined authentication method list is used as the default method for Enable authentication. |
|                          | <i>method</i>  | It must be one of the keywords: <b>local</b> , <b>none</b> and <b>group</b> . One method list can contain up to four methods.          |
|                          | <b>local</b>   | Uses the local user name database for authentication.                                                                                  |
|                          | <b>none</b>    | Does not perform authentication.                                                                                                       |
|                          | <b>group</b>   | Uses the server group for authentication. At present, the RADIUS and TACACS+ server groups are supported.                              |

**Defaults** N/A

**Command** Global configuration mode  
**Mode**

**Usage Guide** If the AAA Enable authentication service is enabled on the device, users must use AAA for Enable authentication negotiation. You must use the **aaa authentication enable** command to configure a default or optional method list for Enable authentication.

The next method can be used for authentication only when the current method does not work.

The Enable authentication function automatically takes effect after configuring the Enable authentication method list.

**Configuration Examples** The following example defines an AAA Enable authentication method list. In the authentication method list, first the RADIUS security server is used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

```
Ruijie(config)# aaa authentication enable default group radius local
```

#### Related Commands

| Command              | Description                       |
|----------------------|-----------------------------------|
| <b>aaa new-model</b> | Enables the AAA security service. |
| <b>enable</b>        | Switchover the user level.        |
| <b>username</b>      | Defines a local user database.    |

**Platform** N/A

**Description**

## 1.7 aaa authentication login

Use this command to enable AAA Login authentication and configure the Login authentication method list. Use the **no** form of this command to delete the authentication method list.

**aaa authentication login { default | list-name } method1 [ method2..]**

**no aaa authentication login { default | list-name }**

#### Parameter Description

| Parameter        | Description                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>default</b>   | When this parameter is used, the following defined authentication method list is used as the default method for Login authentication.       |
| <i>list-name</i> | Name of the user authentication method list, which could be any character strings                                                           |
| <i>method</i>    | It must be one of the keywords: <b>local</b> , <b>none</b> , <b>group</b> and <b>subs</b> . One method list can contain up to four methods. |
| <b>local</b>     | Uses the local user name database for authentication.                                                                                       |
| <b>none</b>      | Does not perform authentication.                                                                                                            |
| <b>group</b>     | Uses the server group for authentication. At present, the RADIUS and TACACS+ server groups are supported.                                   |
| <b>subs</b>      | Uses the subs database for authentication.                                                                                                  |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** If the AAA Login authentication security service is enabled on the device, users must use AAA for Login authentication negotiation. You must use the **aaa authentication login** command to configure a default or optional method list for Login authentication.

The next method can be used for authentication only when the current method does not work.

You need to apply the configured Login authentication method to the terminal line which needs Login authentication. Otherwise, the configured Login authentication method is invalid.

**Configuration** The following example defines an AAA Login authentication method list named list-1. In the

**Examples** authentication method list, first the RADIUS security server is used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

```
Ruijie(config)# aaa authentication login list-1 group radius local
```

|-----------------------------|----------------------------------------------------------------|
| <b>aaa new-model</b>        | Enables the AAA security service.                              |
| <b>login authentication</b> | Applies the Login authentication method to the terminal lines. |
| <b>username</b>             | Defines a local user database.                                 |

**Platform** N/A

**Description**

## 1.8 aaa authentication ppp

Use this command to enable the AAA authentication for PPP user and configure the PPP user authentication method list.

Use the **no** form of this command to delete the authentication method list.

**aaa authentication ppp { default | list-name } method1 [ method2...]**

**no aaa authentication ppp { default | list-name }**

**Parameter  
Description**

| Parameter        | Description                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>default</b>   | When this parameter is used, the following defined authentication method list is used as the default method for PPP user authentication.    |
| <i>list-name</i> | Name of the user authentication method list, which could be any character strings                                                           |
| <i>method</i>    | It must be one of the keywords: <b>local</b> , <b>none</b> , <b>group</b> and <b>subs</b> . One method list can contain up to four methods. |
| <b>local</b>     | Uses the local user name database for authentication.                                                                                       |
| <b>none</b>      | Does not perform authentication.                                                                                                            |
| <b>group</b>     | Uses the server group for authentication. At present, the RADIUS server group is supported.                                                 |
| <b>subs</b>      | Uses the subs database for authentication.                                                                                                  |

**Defaults** N/A

**Command  
Mode** Global configuration mode

**Usage Guide** If the AAA PPP security service is enabled on the device, users must use AAA authentication for PPP negotiation. You must use the **aaa authentication ppp** command to configure a default or optional method list for PPP user authentication.

The next method can be used for authentication only when the current method does not work.

**Configuration** The following example defines an AAA authentication method list named `rds_ppp` for PPP session. In the authentication method list, first the RADIUS security server is used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

**Examples**

```
Ruijie(config)# aaa authentication ppp rds_ppp group radius local
```

**Related Commands**

|---------------------------|------------------------------------------------------|
| <b>aaa new-model</b>      | Enables the AAA security service.                    |
| <b>ppp authentication</b> | Associates a specific method list with the PPP user. |
| <b>username</b>           | Defines a local user database.                       |

**Platform** N/A

**Description**

## 1.9 aaa authentication sslvpn

Use this command to enable AAA authentication for the SSL VPN user and configure the SSL VPN user authentication method list.

Use the **no** form of this command to delete the authentication method list.

**aaa authentication sslvpn { default | list-name } method1 [ method2...]**

**no aaa authentication sslvpn { default | list-name }**

**Parameter Description**

| Parameter        | Description                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>default</b>   | When this parameter is used, the following defined authentication method list is used as the default method for SSL VPN user authentication. |
| <i>list-name</i> | Name of SSL VPN user authentication method list, which could be any character strings                                                        |
| <i>method</i>    | It must be one of the keywords: <b>local</b> , <b>none</b> , <b>subs</b> and <b>group</b> . One method list can contain up to four methods.  |
| <b>local</b>     | Use the local user name database for authentication.                                                                                         |
| <b>none</b>      | Does not perform authentication.                                                                                                             |
| <b>group</b>     | Uses the server group for authentication. At present, the RADIUS server group is supported.                                                  |
| <b>subs</b>      | Uses the subs database for authentication.                                                                                                   |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** If the SSL VPN security service is enabled on the device, users must use the AAA authentication for SSL VPN negotiation. You must use the **aaa authentication sslvpn** command to configure a default

or optional method list for user authentication.

The next method can be used for authentication only when the current method does not work.

**Configuration Examples** The following example defines an AAA authentication method list named **rds\_sslvpn** for SSL VPN session. In the authentication method list, the RADIUS security server is first used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

```
Ruijie(config)# aaa authentication sslvpn rds_sslvpn group radius local
```

**Description**

## 1.10 aaa authorization commands

Use this command to authorize the command executed by the user who has logged in the NAS CLI.

Use the **no** form of this command to restore the default setting.

**aaa authorization commands** *level* { **default** | *list-name* } *method1* [ *method2...*]

**no aaa authorization commands** *level* { **default** | *list-name* }

| Parameter Description | Parameter        | Description                                                                                                             |
|-----------------------|------------------|-------------------------------------------------------------------------------------------------------------------------|
|                       | <i>level</i>     | Command level to be authorized in the range from 0 to 15                                                                |
|                       | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for command authorization. |
|                       | <i>list-name</i> | Name of the user authorization method list, which could be any character strings                                        |
|                       | <i>method</i>    | It must be one of the keywords: <b>none</b> and <b>group</b> . One method list can contain up to four methods.          |
|                       | <b>none</b>      | Does not perform authorization.                                                                                         |
|                       | <b>group</b>     | Uses the server group for authorization. At present, the TACACS+ server group is supported.                             |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS supports authorization of the commands executed by the users. When the users input and attempt to execute a command, AAA sends this command to the security server. This command is to be executed if the security server allows to. Otherwise, it will prompt command deny. It is necessary to specify the command level when configuring the command authorization, and this specified command level is the default command level. The configured command authorization method must be applied to terminal line which requires the

command authorization. Otherwise, the configured command authorization method is ineffective.

**Configuration** The following example uses the TACACS+ server to authorize the level 15 command.

**Examples** Ruijie(config)# aaa authorization commands 15 default group tacacs+

| Related<br>Commands | Command                | Description                                              |
|---------------------|------------------------|----------------------------------------------------------|
|                     | aaa new-model          | Enables the AAA security service.                        |
|                     | authorization commands | Applies the command authorization for the terminal line. |

**Platform** N/A

**Description**

## 1.11 aaa authorization config-commands

Use this command to authorize the configuration commands (including in the global configuration mode and its sub-mode). Use the **no** form of this command to restore the default setting.

**aaa authorization config-commands**

**no aaa authorization config-commands**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** If you only authorize the commands in the non-configuration mode (for example, privileged EXEC mode), you can use the **no** form of this command to disable the authorization function in the configuration mode, and execute the commands in the configuration mode and its sub-mode without command authorization.

**Configuration** The following example enables the configuration command authorization function.

**Examples** Ruijie(config)# aaa authorization config-commands

| Related<br>Commands | Command                    | Description                            |
|---------------------|----------------------------|----------------------------------------|
|                     | aaa new-model              | Enables the AAA security service.      |
|                     | aaa authorization commands | Defines the AAA command authorization. |

**Platform** N/A

**Description**

## 1.12 aaa authorization console

Use this command to authorize the commands of the users who have logged in the console. Use the **no** form of this command to restore the default setting.

**aaa authorization console**

**no aaa authorization console**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS supports to identify the users logged in from the console and from other terminals, configure whether to authorize the users logged in from the console or not. If the command authorization function is disabled on the console, the authorization method list applied to the console line is ineffective.

**Configuration Examples** The following example enables the aaa authorization console function.

```
Ruijie(config)# aaa authorization console
```

| Related Commands | Command                           | Description                                             |
|------------------|-----------------------------------|---------------------------------------------------------|
|                  | <b>aaa new-model</b>              | Enables the AAA security service.                       |
|                  | <b>aaa authorization commands</b> | Defines the AAA command authorization.                  |
|                  | <b>authorization commands</b>     | Applies the command authorization to the terminal line. |

**Platform** N/A

**Description**

## 1.13 aaa authorization exec

Use this command to authorize the users logged in the NAS CLI and assign the authority level. Use the **no** form of this command to restore the default setting.

**aaa authorization exec { default | list-name } method1 [ method2...]**

**no aaa authorization exec { default | list-name }**

| Parameter   | Parameter        | Description                                                                                                          |
|-------------|------------------|----------------------------------------------------------------------------------------------------------------------|
| Description | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for Exec authorization. |
|             | <i>list-name</i> | Name of the user authorization method list, which could be any character strings                                     |

|               |                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------|
| <i>method</i> | It must be one of the keywords listed in the following table. One method list can contain up to four methods. |
| <b>local</b>  | Uses the local user name database for authorization.                                                          |
| <b>none</b>   | Does not perform authorization.                                                                               |
| <b>group</b>  | Uses the server group for authorization. At present, the RADIUS server group is supported.                    |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS supports authorization of users logged in the NAS CLI and assignment of CLI authority level(0-15). The aaa authorization exec function is effective on condition that Login authentication function has been enabled. It can not enter the CLI if it fails to enable the aaa authorization exec. You must apply the exec authorization method to the terminal line; otherwise the configured method is ineffective.

**Configuration** The following example uses the RADIUS server to authorize Exec.

**Examples** Ruijie(config)# aaa authorization exec default group radius

| Related Commands | Command                   | Description                                             |
|------------------|---------------------------|---------------------------------------------------------|
|                  | <b>aaa new-model</b>      | Enables the AAA security service.                       |
|                  | <b>authorization exec</b> | Applies the command authorization to the terminal line. |
|                  | <b>username</b>           | Defines a local user database.                          |

**Platform** N/A

**Description**

## 1.14 aaa authorization network

Use this command to authorize the service requests (including such protocols as PPP and SLIP) from the users that access the network. Use the **no** form of this command to restore the default setting.

**aaa authorization network { default | list-name } method1 [ method2...]**

**no aaa authorization network { default | list-name }**

| Parameter Description | Parameter      | Description                                                                                                             |
|-----------------------|----------------|-------------------------------------------------------------------------------------------------------------------------|
|                       | <b>default</b> | When this parameter is used, the following defined method list is used as the default method for Network authorization. |
|                       | <i>method</i>  | It must be one of the keywords: <b>none</b> and <b>group</b> . One method list can contain up to four methods.          |
|                       | <b>none</b>    | Does not perform authorization.                                                                                         |
|                       | <b>group</b>   | Uses the server group for authorization. At present, the RADIUS                                                         |

|  |                            |
|--|----------------------------|
|  | server group is supported. |
|--|----------------------------|

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS supports authorization of all the service requests related to the network, such as PPP and SLIP. If authorization is configured, all the authenticated users or interfaces will be authorized automatically.

Three different authorization methods can be specified. Like authorization, the next method can be used for authorization only when the current authorization method does not work. If the current authorization method fails, other subsequent authorization method is not used.

The RADIUS server authorizes authenticated users by returning a series of attributes. Therefore, RADIUS authorization is based on RADIUS authorization. RADIUS authorization is performed only when the user passes the RADIUS authorization.

**Configuration** The following example uses the RADIUS server to authorize network services.

**Examples** Ruijie(config)# aaa authorization network default group radius

| <b>Related Commands</b> | Command                   | Description                       |
|-------------------------|---------------------------|-----------------------------------|
|                         | <b>aaa new-model</b>      | Enables the AAA security service. |
|                         | <b>aaa accounting</b>     | Defines AAA accounting.           |
|                         | <b>aaa authentication</b> | Defines AAA authentication.       |
|                         | <b>username</b>           | Defines a local user database.    |

**Platform** N/A

**Description**

## 1.15 aaa command-author cache

Use this command to cache authorization results on the AAA module.

Use the **no** form of this command to restore the default setting.

**aaa command-author cache**

**no aaa command-author cache**

| <b>Parameter</b>   | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** By default, the AAA module does not cache authorization results.

**Command Mode** Global configuration mode

**Usage Guide** The AAA module caches authorization results returned from the server. Therefore, later authorizations at the same level can be operated based on the cached resources.

The cached authorization results, originating from specific levels of sessions and commands, can be applied only to sessions and commands at these levels.

**Configuration** The following example enables the AAA module to cache authorization results.

**Examples**

```
Ruijie(config)# aaa command-author cache
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Description**

## 1.16 aaa domain

Use this command to configure the domain attributes. Use the **no** form of this command to restore the default setting.

**aaa domain { default | domain-name }**

**no aaa domain { default | domain-name }**

| Parameter<br>Description | Parameter          | Description                                          |
|--------------------------|--------------------|------------------------------------------------------|
|                          | <b>default</b>     | Uses this parameter to configure the default domain. |
|                          | <i>domain-name</i> | The name of the specified domain                     |

**Defaults** No domain is configured by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to configure the domain-name-based AAA service. The **default** is to configure the default domain. That is the method list used by the network device if the users are without domain information. The *domain-name* is the specified domain name, if the users are with this domain name, the method lists associated with this domain are used. At present, the system can configure up to 32 domains.

**Configuration** The following example configures the domain name.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)#
```

|                     | <b>aaa authentication</b> | Defines a user authentication method list. |
|                     | <b>aaa authorization</b>  | Defines a user authorization method list.  |
|                     | <b>aaa accounting</b>     | Defines a user accounting method list.     |

**Platform** N/A**Description**

## 1.23 aaa slave-login allow

Use this command to turn on the login switch for the AAA slave device.

Use the **no** form of this command to turn off the login switch..

**aaa slave-login allow**

**no aaa slave-login allow**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** By default, the switch is off, so the slave device is not allowed to login.

**Command Mode** Domain configuration mode

**Usage Guide** When the switch is turned on, the slave device is allowed to login; otherwise, the slave device cannot login.

The configuration remains valid unless a change is made.

**Configuration Examples** The following example turns on the login switch for the AAA slave device.

```
Ruijie(config)# aaa slave-login allow
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** This command is supported on switches.

## 1.24 accounting

Use this command to configure the Commands, EXEC, or Network accounting list.

Use the **no** form of this command to restore the default setting.

**accounting {commands | exec | network} { default | list-name }**

**no accounting {commands | exec | network }**

| Parameter   | Parameter        | Description                                              |
|-------------|------------------|----------------------------------------------------------|
| Description | <b>default</b>   | Uses this parameter to specify the default method list.  |
|             | <i>list-name</i> | The name of the network accounting list                  |
|             | <b>commands</b>  | Uses this parameter to specify the Commands method list. |
|             | <b>exec</b>      | Uses this parameter to specify the EXEC method list.     |
|             | <b>network</b>   | Uses this parameter to specify the Network method list.  |

**Defaults** With no method list specified, if the user sends the request, the device will attempt to specify the default method list for the user.

**Command Mode** Domain configuration mode

**Usage Guide** Use this command to configure the Commands, EXEC, or Network accounting method list for the specified domain.

**Configuration** The following example sets an accounting method list for the specified domain.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# accounting network default
Ruijie(config-aaa-domain)# accounting exec default
Ruijie(config-aaa-domain)# accounting commands default
```

| Related<br>Commands | Command                  | Description                                |
|---------------------|--------------------------|--------------------------------------------|
|                     | <b>aaa new-model</b>     | Enables the AAA security service.          |
|                     | <b>aaa domain enable</b> | Enables the domain-name-based AAA service. |
|                     | <b>show aaa domain</b>   | Displays the domain configuration.         |

**Platform** N/A

**Description**

## 1.25 authentication

Use this command to configure the IEEE802.1x, login, or enable authentication list.

Use the **no** form of this command to restore the default setting.

**authentication { login | enable } { default | list-name }**

**no authentication { login | enable }**

| Parameter<br>Description | Parameter        | Description                                                      |
|--------------------------|------------------|------------------------------------------------------------------|
|                          | <b>default</b>   | Uses this parameter to specify the default method list           |
|                          | <i>list-name</i> | The name of the specified method list                            |
|                          | <b>login</b>     | Uses this parameter to configure the login authentication list.  |
|                          | <b>enable</b>    | Uses this parameter to configure the enable authentication list. |

**Defaults** With no method list specified, if users send the request, the device will attempt to specify the default method list for users.

**Command Mode** Domain configuration mode

**Usage Guide** Specify an authentication method list for the domain.

**Configuration** The following example sets an Enable authentication method list for the specified domain.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# authentication enable default
```

| Related<br>Commands | Command                  | Description                                |

|                     | <b>aaa new-model</b>     | Enables the AAA security service.          |
|                     | <b>aaa domain enable</b> | Enables the domain-name-based AAA service. |
|                     | <b>show aaa domain</b>   | Displays the domain configuration.         |

**Platform** N/A

**Description**

## 1.26 authorization

Use this command to configure the Commands, EXEC, or Network authorization list.

Use the **no** form of this command to restore the default setting.

**authorization { commands | exec | network } { default | list-name }**

**no authorization { commands | exec | network }**

| Parameter<br>Description | Parameter        | Description                                              |
|--------------------------|------------------|----------------------------------------------------------|
|                          | <b>default</b>   | Uses this parameter to specify the default method list.  |
|                          | <i>list-name</i> | The name of the specified method list                    |
|                          | <b>commands</b>  | Uses this parameter to specify the Commands method list. |
|                          | <b>exec</b>      | Uses this parameter to specify the EXEC method list.     |
|                          | <b>network</b>   | Uses this parameter to specify the Network method list.  |

**Defaults** With no method list specified, if users send the request, the device will attempt to specify the default method list for users.

**Command Mode** Domain configuration mode

**Usage Guide** Specify an authorization method list for the domain.

**Configuration** The following example sets an authorization method list for the specified domain.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# authorization network default
Ruijie(config-aaa-domain)# authorization exec default
Ruijie(config-aaa-domain)# authorization commands default
```

|                          | <b>by-id session-id</b>  | Displays the information of the AAA user that with a specified session ID. |
|                          | <b>by-name user-name</b> | Displays the information of the AAA user with a specified user name.       |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ Global configuration mode/ Interface configuration mode

**Usage Guide** Use this command to display AAA user information.

**Configuration Examples** The following example displays AAA user information.

```
Ruijie#show aaa user all
-----
      Id ----- Name
2345687901      wwxy
-----

Ruijie# show aaa user by-id 2345687901
-----
      Id ----- Name
2345687901      wwxy

Ruijie# show aaa user by-name wwxy
-----
```

```

      Id ----- Name
2345687901      wwxy
-----

Ruijie# show aaa user logout

Name                               Tries      Lock      Timeout (min)
-----
Ruijie#

```

## 1.34 state

Use this command to set whether the configured domain is valid. Use the **no** form of this command to restore the default setting.

**state { block | active }**

**no state**

| Parameter Description | Parameter     | Description                       |
|-----------------------|---------------|-----------------------------------|
|                       | <b>block</b>  | The configured domain is invalid. |
|                       | <b>active</b> | The configured domain is valid.   |

**Defaults** The default is active.

**Command Mode** Domain configuration mode

**Usage Guide** Use this command to set whether the specified configured domain is valid.

**Configuration Examples** The following example sets the configured domain to be invalid.

```

Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# state block

```

## 1.35 username-format

Use this command to configure the user name whether to be with the domain information when the NAS interacts with the servers. Use the **no** form of this command to restore the default setting.

**username-format** { **without-domain** | **with-domain** }

**no username-format**

| Parameter   | Parameter             | Description                                        |
|-------------|-----------------------|----------------------------------------------------|
| Description | <b>without-domain</b> | Sets the user name without the domain information. |
|             | <b>with-domain</b>    | Sets the user name with the domain information.    |

**Defaults** The default is without-domain.

**Command Mode** Domain configuration mode

**Usage Guide** Use this command to configure the user name whether to be with the domain information when the NAS interacts with the servers.

**Configuration** The following example sets the user name without the domain information.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# username-domain without-domain
```

## 2 RADIUS Commands

### 2.1 aaa group server radius

Use this command to enter AAA server group configuration mode. Use the **no** form of this command to restore the default setting.

**aaa group server radius** *name*

**no aaa group server radius** *name*

| Parameter<br>Description | Parameter   | Description                                                                                                                     |
|--------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>name</i> | Server group name. Keywords “radius” and “tacacs +” are excluded as they are the default RADIUS and TACACS+ server group names. |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure a RADIUS AAA server group.

**Configuration** The following example configures a RADIUS AAA server group named ss.

**Examples**

```
Ruijie(config)# aaa group server radius ss
Ruijie(config-gs-radius)# end
Ruijie# show aaa group
Type      Reference  Name
-----
radius    1          radius
tacacs+   1          tacacs+
radius    1          ss
```

**Platform Description** N/A

### 2.2 ip radius source-interface

Use this command to specify the source IP address for the RADIUS packets. Use the **no** form of this command to delete the source IP address for the RADIUS packet.

**ip radius source-interface** *interface*

**no radius source-interface**

**Parameter  
Description**

| Parameter        | Description                                                           |
|------------------|-----------------------------------------------------------------------|
| <i>interface</i> | Interface that the source IP address of the RADIUS packet belongs to. |

**Defaults**

The source IP address of the RADIUS packet is set by the network layer.

**Command  
mode**

Global configuration mode

**Usage Guide**

In order to reduce the NAS information to be maintained on the RADIUS server, use this command to set the source IP address of the RADIUS packet. This command uses the first IP address of the specified interface as the source IP address of the RADIUS packet. This command is used in the layer 3 devices.

**Configuration  
Examples**

The following example specifies that the RADIUS packet obtains an IP address from the fastEthernet 0/0 interface and uses it as the source IP address of the RADIUS packet.

```
Ruijie(config)# ip radius source-interface fastEthernet 0/0
```

**Related  
Commands**

| Command                   | Description                                 |
|---------------------------|---------------------------------------------|
| <b>radius-server host</b> | Defines the RADIUS server.                  |
| <b>ip address</b>         | Configures the IP address of the interface. |

**Description**

## 2.3 ip oob

Use this command to specify the MGMT port used in the TACACS+ server group.

Use the **no** form of this command to restore the default setting.

**ip oob** [ *via mgmt\_name* ]

**no ip oob**

**Parameter  
Description**

| Parameter        | Description    |
|------------------|----------------|
| <i>mgmt_name</i> | MGMT port name |

**Defaults**

N/A

**Command**

TACACS+ server group configuration mode

**Mode**

**Usage Guide** Use the **aaa group server tacacs+** command to enter TACACS+ server group configuration mode. If no port is specified as the MGMT port, MGMT Port 0 is default.

**Configuration** The following example specifies MGMT port 1 used in the TACACS+ server group.

**Examples**

```
Ruijie(config)# aaa group server radius ss
Ruijie(config-gs-radius)# server 192.168.4.14
Ruijie(config-gs-radius)# server 192.168.4.15
Ruijie(config-gs-radius)# ip oob via mgmt 1
Ruijie(config-gs-radius)# end
```

## 2.4 ip vrf forwarding

Use this command to select a VRF for the AAA server group. Use the **no** form of this command to restore the default setting.

**ip vrf forwarding** *vrf\_name*

**no ip vrf forwarding**

**Parameter  
Description**

| Parameter       | Description |
|-----------------|-------------|
| <i>vrf_name</i> | VRF name.   |

**Defaults** N/A

**Command** Server group configuration mode

**Mode**

**Usage Guide** This command is used to select a VRF for the specified server.

**Configuration** The following example selects the VRF named *vrf\_name* for AAA server group *ss*.

**Examples**

```
Ruijie(config)# aaa group server radius ss
Ruijie(config-gs-radius)# server 192.168.4.12
Ruijie(config-gs-radius)# server 192.168.4.13
Ruijie(config-gs-radius)# ip vrf forwarding vrf_name
Ruijie(config-gs-radius)# end
```

## 2.5 radius vendor-specific extend

Use this command to extend RADIUS not to differentiate the IDs of private vendors. Use the **no** form of this command to restore the default setting.

**radius vendor-specific extend**

**no radius vendor-specific extend**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

Defaults Only the private vendor IDs of Ruijie are recognized.

Command Global configuration mode  
Mode

Usage Guide This command is used to identify the attributes of all vendor IDs by type.

Configuration The following example extends RADIUS so as not to differentiate the IDs of private vendors:

Examples 

```
Ruijie(config)# radius vendor-specific extend
```

| Related Commands | Command                   | Description                                                                     |
|------------------|---------------------------|---------------------------------------------------------------------------------|
|                  | <b>radius attribute</b>   | Configures vendor type.                                                         |
|                  | <b>radius set qos cos</b> | Sets the qos value sent by the RADIUS server as the cos value of the interface. |

Platform N/A  
Description

## 2.6 radius-server account update retransmit

Use this command to configure accounting update packet retransmission for the authentication user.

Use the **no** form of this command to restore the default setting,

**radius-server account update retransmit**

**no radius-server account update retransmit**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure accounting update packet retransmission for the second generation Web authentication user exclusively.

**Configuration Examples** The following example configures accounting update packet retransmission for the second generation Web authentication user.

```
Ruijie(config)#radius-server account update retransmit
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform Description** N/A

## 2.7 radius-server attribute 31

Use this command to specify the MAC-based format of RADIUS Calling-Station-ID attribute in global configuration mode. Use the **no** form of this command to restore the default setting.

**radius-server attribute 31 mac format { ietf | normal | unformatted }**

**no radius-server attribute 31 mac format**

| Parameter<br>Description | Parameter          | Description                                                                                                      |
|--------------------------|--------------------|------------------------------------------------------------------------------------------------------------------|
|                          | <b>ietf</b>        | The standard format specified by the IETF RFC3580 . '-'is used as the separator, for example: 00-D0-F8-33-22-AC. |
|                          | <b>normal</b>      | Normal format representing the MAC address. ':'is used as the separator. For example: 00d0.f833.22ac.            |
|                          | <b>unformatted</b> | No format and separator. By default, unformatted is used. For example: 00d0f83322ac.                             |

**Defaults** The default format is unformatted.

**Command Mode** Global configuration mode

**Usage Guide** Some RADIUS security servers (mainly used to 802.1x authentication) may identify the IETF format only. In this case, the RADIUS Calling-Station-ID attribute shall be set as the IETF format type.

**Configuration** The following example defines the RADIUS Calling-Station-ID attribute as IETF format.

**Examples** Ruijie(config)# radius-server attribute 31 mac format ietf

| Related Commands | Command            | Description                |
|------------------|--------------------|----------------------------|
|                  | radius-server host | Defines the RADIUS server. |

**Platform** N/A

**Description**

## 2.8 radius-server dead-criteria

Use this command to configure criteria on a device to determine that the Radius server is unreachable. Use the no form of this command to restore the default setting.

**radius-server dead-criteria { time *seconds* [ tries *number* ] | tries *number* }**

**no radius-server dead-criteria { time *seconds* [ tries *number* ] | tries *number* }**

| Parameter Description | Parameter                  | Description                                                                                                                                                                                                                                                         |
|-----------------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>time <i>seconds</i></b> | Configures the timeout value. If the device does not receive a correct response packet from the Radius server within the specified time, the Radius server is considered to be unreachable. The value is in the range from 1 to 120 in the unit of seconds.         |
|                       | <b>tries <i>number</i></b> | Configures the successive timeout times. When sending a request from the device to the Radius server times out for the specified times, the device considers that the Radius server is unreachable. The value is in the range from 1 to 100 in the unit of seconds. |

**Defaults** The default **time *seconds*** is 60 and **tries *number*** is 10.

**Command Mode** Global configuration mode

**Usage Guide** If a Radius server meets the timeout and timeout times at the same time, it is considered to be unreachable. This command is used to adjust the parameter conditions of timeout and timeout times.

**Configuration** The following example sets the timeout to 120 seconds and timeout times to 20.

**Examples** Ruijie(config)# radius-server dead-criteria time 120 tries 20

|                 | <b>radius-server host</b>     | Defines the RADIUS security server.                                                            |
|                 | <b>radius-server deadtime</b> | Defines the duration when a device stops sending any requests to an unreachable Radius server. |
|                 | <b>radius-server timeout</b>  | Defines the timeout for the packet re-transmission.                                            |

**Platform** N/A

**Description**

## 2.9 radius-server deadtime

Use this command to configure the duration when a device stops sending any requests to an unreachable Radius server. Use the **no** form of this command to restore the default setting.

**radius-server deadtime** *minutes*

**no radius-server deadtime**

|                              |                  |                                                                                                                                                                               |
|------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b> | <b>Description</b>                                                                                                                                                            |
|                              | <i>minutes</i>   | Defines the duration in minutes when the device stops sending any requests to the unreachable Radius server. The value is in the range from 1 to 1440 in the unit of minutes. |

**Defaults** The default value of minutes is 0, that is, the device keeps sending requests to the unreachable Radius server.

**Command Mode** Global configuration mode.

**Usage Guide** If active Radius server detection is enabled on the device, the time parameter of this command does not take effect on the Radius server. Otherwise, the Radius server becomes reachable when the duration set by this command is shorter than the unreachable time..

**Configuration Examples** The following example sets the duration when the device stops sending requests to 1 minute.

```
Ruijie(config)# radius-server deadtime 1
```

|                         |                                    |                                                                        |
|-------------------------|------------------------------------|------------------------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>                     | <b>Description</b>                                                     |
|                         | <b>radius-server host</b>          | Defines the RADIUS security server.                                    |
|                         | <b>radius-server dead-criteria</b> | Defines the criteria to determine that a Radius server is unreachable. |

**Platform** N/A

**Description**

## 2.10 radius-server host

Use this command to specify a RADIUS security server host. Use the **no** form of this command to restore the default setting.

```
radius-server host [ oob ] [ via mgmt-name ] { ipv4-address } [ auth-port port-number ] [ acct-port port-number ] [ test username name [ idle-time time ] [ ignore-auth-port ] [ ignore-acct-port ] ] [ key [ 0 | 7 ] text-string ]
no radius-server host { ipv4-address }
```

**Parameter**  
**Description**

| Parameter                                             | Description                                                                                                                                                                               |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>oob</b> [ <i>via mgmt-name</i> ]                   | Specifies an MGMT port as the source port for TACACS+ communication.                                                                                                                      |
| <i>ipv4-address</i>                                   | IPv6 address of the RADIUS security server host.                                                                                                                                          |
| <i>auth-port</i>                                      | UDP port used for RADIUS authentication.                                                                                                                                                  |
| <i>port-number</i>                                    | Number of the UDP port used for RADIUS authentication. If it is set to 0, this host does not perform authentication.                                                                      |
| <i>acct-port</i>                                      | UDP port used for RADIUS accounting.                                                                                                                                                      |
| <i>port-number</i>                                    | Number of the UDP port used for RADIUS accounting. If it is set to 0, this host does not perform accounting.                                                                              |
| <b>test username</b> <i>name</i>                      | (Optional) Enables the active detection to the RADIUS security server and specify the username used by the active detection.                                                              |
| <b>idle-time</b> <i>time</i>                          | (Optional) Sets the interval of sending the test packets to the reachable RADIUS security server, which is 60 minutes by default and in the range of 1 to 1440 minutes (namely 24 hours). |
| <b>ignore-auth-port</b>                               | (Optional) Disables the detection to the authentication port on the RADIUS security server. It is enabled by default.                                                                     |
| <b>ignore-acct-port</b>                               | (Optional) Disables the detection to the authentication port on the RADIUS security server. It is enabled by default.                                                                     |
| <b>key</b> [ <b>0</b>   <b>7</b> ] <i>text-string</i> | Configure a shared key for the server. The type of encryption can be specified. 0 is no encryption and 7 is simple encryption. The default is 0.                                          |

**Defaults** No RADIUS host is specified by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** In order to implement the AAA security service using RADIUS, you must define a RADIUS security server. You can define one or more RADIUS security servers using the **radius-server host**

command.

**Configuration** The following example defines a RADIUS security server host:

**Examples** Ruijie(config)# radius-server host 192.168.12.1

The following example defines a RADIUS security server host in the IPv4 environment, enable the active detection with the detection interval 60 minutes and disable the accounting UDP port detection:

```
Ruijie(config)# radius-server host 192.168.100.1 test username viven idle-time  
60 ignore-acct-port
```

**Related  
Commands**

| Command                         | Description                                               |
|---------------------------------|-----------------------------------------------------------|
| <b>aaa authentication</b>       | Defines the AAA authentication method list                |
| <b>radius-server key</b>        | Defines a shared password for the RADIUS security server. |
| <b>radius-server retransmit</b> | Defines the number of RADIUS packet retransmissions.      |

**Platform** N/A

**Description**

## 2.11 radius-server key

Use this command to define a shared password for the network access server (device) to communicate with the RADIUS security server. Use the **no** form of this command to restore the default setting.

**radius-server key** [ 0 | 7 ] *text-string*

**no radius-server key**

**Parameter  
Description**

| Parameter          | Description                                                            |
|--------------------|------------------------------------------------------------------------|
| <i>text-string</i> | Text of the shared password                                            |
| <b>0   7</b>       | Password encryption type.<br>0: no encryption;<br>7: Simply-encrypted. |

**Defaults** No shared password is specified by default.

**Command**

**Mode** Global configuration mode.

**Usage Guide** A shared password is the basis for communications between the device and the RADIUS security server. In order to allow the device to communicate with the RADIUS security server, you must define the same shared password on the device and the RADIUS security server.

**Configuration** The following example defines the shared password **aaa** for the RADIUS security server:

**Examples** Ruijie(config)# radius-server key aaa

**Related  
Commands**

| Command                         | Description                                          |
|---------------------------------|------------------------------------------------------|
| <b>radius-server host</b>       | Defines the RADIUS security server.                  |
| <b>radius-server retransmit</b> | Defines the number of RADIUS packet retransmissions. |
| <b>radius-server timeout</b>    | Defines the timeout for the RADIUS packet.           |

**Platform** N/A

**Description**

## 2.12 radius-server retransmit

Use this command to configure the number of packet retransmissions before the device considers that the RADIUS security server does not respond. Use the **no** form of this command to restore the default setting.

**radius-server retransmit** *retries*

**no radius-server retransmit**

**Parameter  
Description**

| Parameter      | Description               |
|----------------|---------------------------|
| <i>retries</i> | Number of retransmissions |

**Defaults** The default is 3.

**Command  
Mode** Global configuration mode.

**Usage Guide** AAA uses the next method to authenticate users only when the current security server for authentication does not respond. When the device retransmits the RADIUS packet for the specified times and the interval between every two retries is timeout, the device considers that the security sever does not respond.

**Configuration** The following example sets the number of retransmissions to 4:

**Examples** Ruijie(config)# radius-server retransmit 4

**Related  
Commands**

| Command                   | Description                              |
|---------------------------|------------------------------------------|
| <b>radius-server host</b> | Defines the RADIUS security server.      |
| <b>radius-server key</b>  | Defines a shared password for the RADIUS |

|                              |                                            |
|------------------------------|--------------------------------------------|
|                              | server.                                    |
| <b>radius-server timeout</b> | Defines the timeout for the RADIUS packet. |

**Platform** N/A

**Description**

## 2.13 radius-server source-port

Use this command to configure the source port to send RADIUS packets. Use the **no** form of this command to restore the default setting.

**radius-server source-port** *port*

**no radius-server source-port**

| Parameter   | Parameter   | Description                                    |
|-------------|-------------|------------------------------------------------|
| Description | <i>port</i> | The port number, in the range from 0 to 65535. |

**Defaults** The default is a random number.

**Command** Global configuration mode  
**Mode**

**Usage Guide** The source port is random by default. This command is used to specify a source port.

**Configuration** The following example configures source port 10000 to send RADIUS packets.

**Examples**  

```
Ruijie(config)# radius-server source-port 10000
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A

**Description**

## 2.14 radius-server timeout

Use this command to set the time for the device to wait for a response from the security server after retransmitting the RADIUS packet. Use the **no** form of this command to restore the default setting.

**radius-server timeout** *seconds*

**no radius-server timeout**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description |           |             |

|                |                                                             |
|----------------|-------------------------------------------------------------|
| <i>seconds</i> | Timeout in the range from 1 to 1000 in the unit of seconds. |
|----------------|-------------------------------------------------------------|

**Defaults** The default is five.

**Command**

**Mode** Global configuration mode

**Usage Guide** This command is used to change the timeout of packet retransmission.

**Configuration** The following example sets the timeout to 10 seconds.

**Examples** Ruijie(config)# radius-server timeout 10

**Related  
Commands**

| Command                         | Description                                              |
|---------------------------------|----------------------------------------------------------|
| <b>radius-server host</b>       | Defines the RADIUS security server.                      |
| <b>radius-server retransmit</b> | Defines the number of the RADIUS packet retransmissions. |
| <b>radius-server key</b>        | Defines a shared password for the RADIUS server.         |

**Platform** N/A

**Description**

## 2.15 radius set qos cos

Use this command to set the qos value sent by the RADIUS server as the cos value of the interface.

Use the **no** form of this command to restore the default setting.

**radius set qos cos**

**no radius set qos cos**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** Set the qos value sent by the RADIUS server as the dscp value.

**Command**

Global configuration mode.

**Mode**

**Usage Guide** This command is used to set the qos value sent by the RADIUS server as the cos value, and the dscp value by default.

**Configuration Examples** The following example sets the qos value sent by the RADIUS server as the cos value of the interface:

```
Ruijie(config)# radius set qos cos
```

**Related  
Commands**

| Command                              | Description                                                           |
|--------------------------------------|-----------------------------------------------------------------------|
| <b>radius vendor-specific extend</b> | Extends RADIUS as as not to differentiate the IDs of private vendors. |

**Platform** N/A  
**Description**

## 2.16 radius support cui

Use this command to enable RADIUS to support the cui function. Use the **no** form of this command to restore the default setting.

**radius support cui**

**no radius support cui**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** This command is used to enable RADIUS to support the cui function.

**Configuration** The following example enables RADIUS to support the cui function.

**Examples**

```
Ruijie(config)# radius support cui
```

**Description**

## 2.17 server auth-port acct-port

Use this command to add the server of the AAA server group. Use the **no** form of this command to restore the default setting.

**server** { *ipv4-addr* } [ **auth-port** *port1* ] [ **acct-port** *port2* ]

**no server** { *ipv4-addr* } [ **auth-port** *port1* ] [ **acct-port** *port2* ]

**Parameter  
Description**

| Parameter      | Description                |
|----------------|----------------------------|
| <i>ip-addr</i> | Server IP address          |
| <i>port1</i>   | Server authentication port |
| <i>port2</i>   | Server accounting port     |

**Defaults** No server is configured by default.

**Command  
Mode** Server group configuration mode

**Usage Guide** N/A

**Configuration  
Examples** The following example adds server 192.168.4.12 to server group ss and sets the accounting port and authentication port to 5 and 6 respectively.

```
Ruijie(config)# aaa group server radius ss
Ruijie(config-gs-radius)# server 192.168.4.12 acct-port 5 auth-port 6
Ruijie(config-gs-radius)# end
Ruijie# show aaa group
Type      Reference  Name
-----
radius    1          radius
tacacs+   1          tacacs+
radius    1          ss
```

## 2.18 show radius acct statistics

Use this command to display RADIUS accounting statistics.

**show radius acct statistics**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command** Global configuration mode/privileged EXEC mode/interface configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example displays RADIUS accounting statistics.

**Examples**

```
Ruijie#show radius acct statistics
Accounting Servers:

Server Index..... 1
Server Address..... 192.168.1.1
Server Port..... 1813
Msg Round Trip Time..... 0 (msec)
First Requests..... 1
Retry Requests..... 1
Accounting Responses..... 0
Malformed Msgs..... 0
Bad Authenticator Msgs..... 0
Pending Requests.....
```

**Description**

## 3 TACACS+ Commands

### 3.1 aaa group server tacacs+

Use this command to configure different groups of TACACS+ server hosts. Use the **no** form of this command to remove a specified TACACS server group.

**aaa group server tacacs+ group\_name**

**no aaa group server tacacs+ group\_name**

**Parameter  
Description**

| Parameter         | Description                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>group_name</i> | TACACS+ server group name, which cannot be <b>radius</b> or <b>tacacs+</b> .<br>The two names are the built-in group name. |

**Defaults** No TACACS+ server group is configured.

**Command  
Mode** Global configuration mode

**Usage Guide** After you group different TACACS+ servers, the tasks of authentication, authorization and accounting can be implemented by different server groups.

**Configuration Examples** The following example configures a TACACS+ server group named tac1, and configures a TACACS+ server with IP address 1.1.1.1 in this group:

```
Ruijie(config)#aaa group server tacacs+ tac1
Ruijie(config-gs-tacacs)# server 1.1.1.1
```

**Related

|--------------------------|--------------------------------------------------------|
| <b>server</b>            | Configures server list of TACACS+ server group.        |
| <b>ip vrf forwarding</b> | Configures VRF name supported by TACACS+ server group. |

**Platform  
Description** N/A

### 3.2 ip tacacs source-interface

Use this command to use the IP address of a specified interface for all outgoing TACACS+ packets.  
Use the **no** form of this command to disable use of the specified interface IP address.

**ip tacacs source-interface** *interface*  
**no ip tacacs source-interface**

**Parameter  
Description**

| Parameter        | Description                                |
|------------------|--------------------------------------------|
| <i>interface</i> | Interface for the outgoing TACACS+ packets |

**Defaults** The source IP address of TACACS+ packets is set on the network layer.

**Command  
Mode** Global configuration mode

**Usage Guide** To decrease the work of maintaining massive NAS messages in TACACS+ server, use this command to use the IP address of a specified interface for all outgoing TACACS+ packets.  
This command specifies the primary IP address of the specified interface as the source address of TACACS+ packets on Layer 3 devices. If the specified interface is in a VRF instance, the route of this VRF instance is used for packet transmission.

**Configuration  
Examples** The following example specifies the IP address of GigabitEthernet 0/0 for the outgoing TACACS+ packets.

```
Ruijie(config)# ip tacacs source-interface gigabitEthernet 0/0
```

**Related  
Commands**

| Command                   | Description                                |
|---------------------------|--------------------------------------------|
| <b>tacacs-server host</b> | Defines a TACACS+ server.                  |
| <b>ip address</b>         | Configures the IP address of an interface. |

**Platform  
Description** N/A

### 3.3 ip oob

Use this command to specify the MGMT port used in the TACACS+ server group.  
Use the **no** form of this command to restore the default setting.

**ip oob** [ *via mgmt\_name* ]  
**no ip oob**

**Parameter  
Description**

| Parameter        | Description    |
|------------------|----------------|
| <i>mgmt_name</i> | MGMT port name |

**Defaults** N/A

**Command** TACACS+ server group configuration mode

**Mode**

**Usage Guide** Use the **aaa group server tacacs+** command to enter TACACS+ server group configuration mode. No MGMT port is specified by default.

**Configuration** The following example specifies MGMT port 1 used in the TACACS+ server group.

**Examples**

```
Ruijie(config)# aaa group server tacacs+ ss
Ruijie(config-gs-tacacs+)# server 1.1.1.1
Ruijie(config-gs-tacacs+)# ip oob via mgmt 1
```

**Platform** N/A

**Description**

### 3.4 ip vrf forwarding

Use this command to configure the VRF used in the TACACS+ server group. Use the **no** form of this command to remove the VRF configuration from the TACACS+ server group.

**ip vrf forwarding** *vrf-name*

**no ip vrf forwarding**

**Parameter  
Description**

| Parameter       | Description |
|-----------------|-------------|
| <i>vrf-name</i> | VRF name    |

**Defaults** N/A

**Command** TACACS+ server group configuration mode

**Mode**

**Usage Guide** Before you configure this command, you need to use the **aaa group server tacacs+** command to enter TACACS+ server group configuration mode.

The VRF instance must exist and be configured with a correct VRF name through the **vrf definition** command.

**Configuration** The following example specifies the VRF instance named vpn1 for the TACACS+ server group:

**Examples**

```
Ruijie(config)# aaa group server tacacs+ tac1
Ruijie(config-gs-tacacs+)# server 1.1.1.1
Ruijie(config-gs-tacacs+)# ip vrf forwarding vpn1
```

**Related  
Commands**

| Command                         | Description                                       |
|---------------------------------|---------------------------------------------------|
| <b>aaa group server tacacs+</b> | Configures the TACACS+ server group.              |
| <b>server</b>                   | Configures a server list of TACACS+ server group. |

**Platform** N/A

**Description**

### 3.5 nas-ip

Use this command to configure the source IP address of the TACACS+ packets sent from the TACACS+ server group.

Use the **no** form of this command to remove the source IP address.

**nas-ip** {*ipv4-address* | *ipv6-address*}

**no nas-ip** {*ipv4-address* | *ipv6-address*}

**Parameter  
Description**

| Parameter           | Description                                              |
|---------------------|----------------------------------------------------------|
| <i>ipv4-address</i> | Specifies a source IPv4 address for the TACACS+ packets. |
| <i>ipv6-address</i> | Specifies a source IPv6 address for the TACACS+ packets. |

**Defaults** No source IP address is configured by default.

**Command  
Mode** TACACS+ server group configuration mode

**Usage Guide** You must configure the **aaa group server tacacs+** command before configuring this command.

**Configuration  
Examples** The following example configures a TACACS+ server group named tac1 and specifies the source IP address as 1.1.1.1.

```
Ruijie(config)# aaa group server tacacs+ tac1
Ruijie(config-gs-tacacs+)# nas-ip 1.1.1.1
```

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform** N/A

**Description**

### 3.6 server

Use this command to configure the IP address of the TACACS+ server for the group server. Use the **no** form of this command to remove the TACACS+ server.

**server** {*ipv4-address* | *ipv6-address*}

**no server** {*ipv4-address* | *ipv6-address*}

| Parameter<br>Description | Parameter           | Description                        |
|--------------------------|---------------------|------------------------------------|
|                          | <i>ipv4-address</i> | IPv4 address of the TACACS+ server |
|                          | <i>ipv6-address</i> | IPv6 address of the TACACS+ server |
|                          |                     |                                    |

**Defaults** No TACACS+ server is configured by default.

**Command Mode** TACACS+ server group configuration mode

**Usage Guide** You must configure the **aaa group server tacacs+** command before configuring this command.  
To configure server address in TACACS+ group server, you must use the **tacacs-server host** command in global configuration mode.  
If there is no response from the first host entry, the next host entry is tried.

**Configuration Examples** The following example configures a TACACS+ server group named tac1 and a TACACS+ server address 1.1.1.1 in this group.

```
Ruijie(config)#aaa group server tacacs+ tac1
Ruijie(config-gs-tacacs+)# server 1.1.1.1
```

| Related<br>Commands | Command                         | Description                        |
|---------------------|---------------------------------|------------------------------------|
|                     | <b>aaa group server tacacs+</b> | Configures a TACACS+ server group. |

**Platform** N/A  
**Description**

## 3.7 show tacacs

Use this command to display the TACACS+ server configuration.

**show tacacs**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the TACACS+ server configuration.

**Examples**

```
Ruijie# show tacacs
Tacacs+ Server : 172.19.192.80/49
Socket Opens: 0
Socket Closes: 0
Total Packets Sent: 0
Total Packets Recv: 0
Reference Count: 0
```

**Related  
Commands**

| Command                   | Description                           |
|---------------------------|---------------------------------------|
| <b>tacacs-server host</b> | Defines a TACACS+ secure server host. |

**Platform** N/A

**Description**

### 3.8 tacacs-server host

Use this command to configure a TACACS+ host. Use the **no** form of this command to remove the TACACS+ host.

**tacacs-server host** [ **oob** ] [ **via** *mgmt-name* ] { *ipv4-address* | *ipv6-address* } [ **port** *integer* ] [ **timeout** *integer* ] [ **key** [ **0** | **7** ] *text-string* ]  
**no tacacs-server host** { *ipv4-address* | *ipv6-address* }

**Parameter  
Description**

| Parameter                                  | Description                                                                                                                                                    |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv4-address</i>                        | IPv4 address of the TACACS+ host                                                                                                                               |
| <i>ipv6-address</i>                        | IPv6 address of the TACACS+ host                                                                                                                               |
| <b>oob</b> [ <b>via</b> <i>mgmt-name</i> ] | Specifies an MGMT port as the source port for TACACS+ communication.                                                                                           |
| <b>port</b> <i>integer</i>                 | Port number of the server. The range is from 1 to 65,535. The default is 49.                                                                                   |
| <b>timeout</b> <i>integer</i>              | Timeout time of TACACS+ host. The range is from 1 to 1,000.                                                                                                    |
| <b>key</b> <i>string</i>                   | Configures an authentication and encryption key. The value can be 0 or 7.<br>0 indicates no encryption, while 7 indicates simple encryption. The default is 0. |

**Defaults** No TACACS+ host is specified by default.

**Command  
Mode** Global configuration mode

**Usage Guide** The TACACS+ host must be configured to implement AAA security service. You can use this command to configure one or multiple TACACS+ hosts.

**Configuration** The following example configures a TACACS+ host.

**Examples** Ruijie(config)# tacacs-server host 192.168.12.1

**Description**

### 3.9 tacacs-server key

Use this command to configure the authentication encryption key used for TACACS+ communications between the access server and the TACACS+ server. Use the **no** form of this command to remove the authentication encryption key.

**tacacs-server key** [ 0 | 7 ] *string*

**no tacacs-server key**

**Parameter  
Description**

| Parameter     | Description                                                                        |
|---------------|------------------------------------------------------------------------------------|
| <i>string</i> | Key string                                                                         |
| 0   7         | Encryption type of key<br>0 indicates no encryption; 7 indicate simple encryption. |

**Defaults** No authentication encryption key is configured by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** Use command to configure a global authentication and encryption key for TACACS+ communication. Use the **key** parameter in the **tacacs-server host** command to configure a server-based key.

**Configuration** The following example defines the authentication encryption key of TACACS+ server as aaa:

**Examples** Ruijie(config)# tacacs-server key aaa

**Related  
Commands**

| Command                   | Description             |

| <b>tacacs-server host</b> | Defines a TACACS+ host. |

**Platform** N/A

**Description**

### 3.10 tacacs-server timeout

Use this command to set the interval for which the server waits for a server host to reply. Use the **no** form of this command to restore the default timeout interval.

**tacacs-server timeout** *seconds*

**no tacacs-server timeout**

| Parameter<br>Description | Parameter      | Description                                                          |
|--------------------------|----------------|----------------------------------------------------------------------|
|                          | <i>seconds</i> | Timeout interval in the range from 1 to 1,000 in the unit of seconds |

**Defaults** The default is 5 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Use command to configure a global timeout interval. Use the **timeout** parameter in the **tacacs-server host** command to configure a server-based interval.

**Configuration Examples** The following example configures the timeout interval to 10 seconds.

```
Ruijie(config)# tacacs-server timeout 10
```

| Related<br>Commands | Command                   | Description                           |

## 4 SCC Commands

### 4.1 Identifier Description

The following is a list of command identifiers used in commands for reference:

| Identifier | Description                                                         |
|------------|---------------------------------------------------------------------|
| vlanlist   | Authentication-exemption VLAN list                                  |
| interval   | Authenticated-user online-status detection interval                 |
| thredshold | The traffic threshold of authenticated-user online-status detection |

### 4.2 auth-mode gateway

Use this command to change the authentication mode configured on the device from access authentication to gateway authentication.

**auth-mode gateway**

Use this command to change the authentication mode configured on the device from gateway authentication to access authentication.

**no auth-mode gateway**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** Access authentication mode

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** The core device that performs access control needs to be enabled with the gateway authentication mode.

**Configuration Examples** The following example changes the authentication mode configured on the device to gateway authentication.

```
Ruijie(config)# auth-mode gateway
Please save config and reload system.
```

**Defaults** Use the **show running** command to display the authentication mode configured on a device.

|                        |                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Prompt Messages</b> | N/A                                                                                                                                                                             |
| <b>Common Errors</b>   | Forget to save the authentication mode configuration change before restarting the device. This error causes that the newly configured authentication mode does not take effect. |
| <b>Platforms</b>       | This command is supported only on switches.                                                                                                                                     |

### 4.3 direct-vlan

Use this command to configure authentication-exemption VLANs.

**direct-vlan** *vlanlist*

Use this command to delete the authentication-exemption VLAN configuration.

**no direct-vlan** *vlanlist*

| Parameter Description | Parameter       | Description                                         |
|-----------------------|-----------------|-----------------------------------------------------|
|                       | <i>vlanlist</i> | VLAN list, which can be a VLAN or a group of VLANs. |

**Defaults** By default, no authentication-exemption VLANs are configured.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** You can use this command to configure authentication-exemption VLANs, so that users in specified VLANs can access the Internet without experiencing dot1x or Web authentication.

**Configuration Examples** The following example configures the VLAN2 as an authentication-exemption VLAN.

```
Ruijie(config)# direct-vlan 2
```

**Verification** Use the **show direct-vlan** command to display the authentication-exemption VLAN configuration.

**Prompt Messages** N/A

**Common Errors** N/A

**Platforms** This command is supported only on switches.

## 4.4 nac-author-user maximum

Use this command to configure the limit on IPv4 user capacity on a port.

**nac-author-user maximum** *max-user-num*

Use this command to remove the limit on the IPv4 user capacity on a port.

**no nac-author-user maximum**

| Parameter Description | Parameter           | Description                                                                    |
|-----------------------|---------------------|--------------------------------------------------------------------------------|
|                       | <i>max-user-num</i> | Defines the maximum number of IPv4 access users. The range is from 1 to 1,024. |

**Defaults** By default, the number of IPv4 access users is not limited.

**Command Mode** Interface configuration mode

**Default Level** 14

**Usage Guide** Use this command to configure the maximum number of IPv4 access users on a port.

**Configuration** The following example restricts the maximum number of IPv4 users to 100 on interface Gi 0/1.

**Examples**

```
Ruijie(config)#int gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#nac-author-user maximum 100
```

**Verification**

1. Use the **show nac-author-user** command to display the current and the maximum numbers of IPv4 access users on all ports.
2. Use the **show nac-author-user interface interface-name** command to display the current and the maximum numbers of IPv4 access users on the specified port.

**Prompt Messages** N/A

**Common Errors** N/A

**Platforms** This command is supported only on switches.

## 4.5 offline-detect interval threshold

Use this command to configure user online-status detection, so that a user is disconnected when its traffic is lower than a specified threshold or is zero in a specified interval.

**offline-detect interval** *interval* **threshold** *threshold*

Use this command to restore the default user online-status detection configuration.

**default offline-detect**

Use this command to disable user online-status detection.

**no offline-detect**

| Parameter<br>Description | Parameter        | Description                                                                                                                                                                                |
|--------------------------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>interval</i>  | Indicates the interval of traffic detection (in minutes). The range is from 1 to 65,535 in minutes on a non-switch device or from 6 to 65,535 in minutes on a switch.                      |
|                          | <i>threshold</i> | Indicates the traffic threshold (in bytes). The range is from 0 to 4,294,967,294 in bytes. The value of 0 indicates that the user is disconnected when no traffic of the user is detected. |

**Defaults** By default, the detection interval is 8 hours and the traffic threshold is 0.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** You can use this command to configure user online-status detection to enable the device to disconnect the authenticated user whose traffic is lower than a specified value and end accounting process.

**Configuration Examples** The following example directly disconnects a user for the user's traffic is lower than 5 Kbytes within 5 minutes.

```
Ruijie(config)#offline-detect interval 5 threshold 5120
```

**Verification** Use the **show running** command to display the configuration of online-status detection for authenticated users.

**Prompt Messages** N/A

**Common Errors** N/A

**Platforms** N/A

## 4.6 show direct-vlan

Use this command to display the authentication-exemption VLAN configuration.

**show direct-vlan**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Command Mode** Privileged EXEC mode

**Level** 14

**Usage Guide** N/A

**Configuration** The following example displays the authentication-exemption VLAN configuration.

**Examples**

```
Ruijie #show direct-vlan
direct-vlan 5,7,100
```

**Prompt Messages** N/A

**Platforms** This command is supported only on switches.

## 4.7 show nac-author-user interface

Use this command to display the capacity limit and current number of IPv4 users on all interfaces or a specified interface.

**show nac-author-user [ interface *interface-name* ]**

| Parameter<br>Description | Parameter             | Description    |
|--------------------------|-----------------------|----------------|
|                          | <i>interface-name</i> | Interface name |

**Command Mode** Privileged EXEC mode

**Level** 14

**Usage Guide** N/A

**Configuration** The following example displays the current number and capacity limit of IPv4 users on interface Gi 0/1.

**Examples**

```
Ruijie#show nac-author-user interface gi 0/1
Port      Cur_num  Max_num
-----
Gi0/1     0        100
```

**Prompt**

N/A

**Messages****Platforms**

This command is supported only on switches.

## 4.8 station-move permit

Use this command to enable authenticated-user migration.

**station-move permit**

Use this command to disable authenticated-user migration.

**no station-move permit**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

Authenticated-user migration is not permitted by default.

**Command  
Mode**

Global configuration mode

**Level**

14

**Usage Guide**

You can enable the authenticated-user migration function to allow the online users to be authenticated again and get online from different physical locations (different ports or VLANs).

**Configuration**

The following example enables authenticated-user migration.

**Examples**

```
Ruijie(config)#station-move permit
```

**Verification**

Use the **show running** command to check whether the authenticated-user migration function is enabled.

**Prompt**

N/A

**Messages****Common  
Errors**

N/A

**Platforms**      This command is supported only on switches.

## 5 Password-Policy Commands

### 5.1 password policy life-cycle

Use this command to set the password lifecycle. Use the **no** form of this command to restore the default setting.

**password policy life-cycle days**

**no password policy life-cycle**

| Parameter<br>Description | Parameter   | Description                                                                    |
|--------------------------|-------------|--------------------------------------------------------------------------------|
|                          | <i>days</i> | Sets the password lifecycle, in the range from 1 to 65535 in the unit of days. |

**Defaults** No password lifecycle is set by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to set the password lifecycle. After the password lifecycle expires, the system reminds you to change the password when you login next time.

 This function is valid for the global password (the **enable password** and the **enable secret** commands) and the local user password (the **username name password password** command) while not valid for the password in line mode.

**Configuration Examples** The following example sets the password lifecycle to 90 days.

```
Ruijie(config)# password policy life-cycle 90
```

|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform Description** N/A

### 5.2 password policy min-size

Use this command to set the minimum length of the password. Use the **no** form of this command to restore the default setting.

**password policy min-size length**

**no password policy min-size**

| <b>Parameter Description</b>  | Parameter                                                                                                                                                                                                                                                                                                                           | Description                                                         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
|                               | <i>length</i>                                                                                                                                                                                                                                                                                                                       | Sets the minimum length of the password, in the range from 1 to 31. |
| <b>Defaults</b>               | The minimum length of the password is 8 by default.                                                                                                                                                                                                                                                                                 |                                                                     |
| <b>Command Mode</b>           | Privileged EXEC mode                                                                                                                                                                                                                                                                                                                |                                                                     |
| <b>Usage Guide</b>            | This command is used to set the minimum length of the password,                                                                                                                                                                                                                                                                     |                                                                     |

### 5.3 password policy no-repeat-times

Use this command to ban the use of passwords used in the past several times. Use the no form of this command to restore the default setting.

**password policy no-repeat-times** *times*

**no password policy no-repeat-times**

| <b>Parameter Description</b> | Parameter                                                                                                                                                                                  | Description                                                                      |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
|                              | <i>times</i>                                                                                                                                                                               | The past several times when passwords are configured, in the range from 1 to 31. |
| <b>Defaults</b>              | This function is disabled by default.                                                                                                                                                      |                                                                                  |
| <b>Command Mode</b>          | Global configuration mode                                                                                                                                                                  |                                                                                  |
| <b>Usage Guide</b>           | After this function is enabled, passwords used in the past several times are recorded. If the new password has been used, the alarm message is displayed and password configuration fails. |                                                                                  |

This command is used to set the maximum number of password entries. When the actual number of password entries exceeds the configured number, the new password overwrites the oldest password.

 This function is valid for the global password (the **enable password** and the **enable secret** commands) and the local user password (the **username name password password** command) while not valid for the password in line mode.

#### Configuration

The following example bans the use of passwords used in the past five times.

#### Examples

```
Ruijie(config)# password policy no-repeat-times 5
```

## 5.4 password policy printable-character-check

Use this command to enable checking special characters in password. Use the **no** form of this command to restore default setting.

**password policy printable-character-check**

**no password policy printable-character-check**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

#### Defaults

This function is enabled by default.

#### Command Mode

Global configuration mode

#### Usage Guide

After strong password and special character check are enabled, if the password only contains special characters, the password is regarded as invalid and a prompt is displayed.

Special characters: ~`!@#\$%^&\*()\_+={}[]\:" ' <>./ and space

#### Configuration Examples

The following example enables checking special characters in password.

Enable strong password check.

```
Ruijie(config)# password policy forced-password-modify
```

Enable checking special characters.

```
Ruijie(config)#password policy printable-character-check
```

## 5.5 password policy strong

Use this command to enable strong password check.

**password policy strong**

**no password policy strong**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

Defaults This function is enabled by default.

Command  
Mode Global configuration mode

Usage Guide If the following two kinds of passwords are set not matching the strength policy, the alarm message is displayed.

1. The password the same as the username.
2. The simple password containing only characters or numbers.

 This function is valid for the global password (the **enable password** and the **enable secret** commands) and the local user password (the **username name password password** command) while not valid for the password in line mode.

Configuration The following example configures the strong password check.

Examples 

```
Ruijie(config)# password policy strong
```

## 5.6 service password-encryption

Use this command to encrypt a password. Use the **no** form of this command to restore default setting.

**service password-encryption****Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command  
Mode** Global configuration mode

**Usage Guide** This command is disabled by default. Various passwords are displayed in plain text, unless they are encrypted. After you run the **service password-encryption** and **show running** or **write** command to save your configuration, the password changes into cipher text. If you disable the command, the password in cipher text cannot be restored to plain text.

**Configuration** The following example encrypts the password:

**Examples** Ruijie(config)# service password-encryption

**Related  
Commands**

## 6 Storm Control Commands

### 6.1 show storm-control

Use this command to display storm suppression information.

**show storm-control** [ *interface-type interface-number* ]

| Parameter<br>Description | Parameter                                        | Description             |
|--------------------------|--------------------------------------------------|-------------------------|
|                          | <i>interface-type</i><br><i>interface-number</i> | Specifies an interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ Global configuration mode /Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays storm control configuration on FastEthernet 0/1.

**Examples**

```
Ruijie# show storm-control gigabitethernet 1/1
Interface Broadcast Control Multicast Control Unicast Control
-----
Gi1/1 Disabled Disabled Disabled
```

| Related<br>Commands | Command              | Description                |
|---------------------|----------------------|----------------------------|
|                     | <b>storm-control</b> | Enables storm suppression. |

**Platform** N/A

**Description**

### 6.2 storm-control

Use this command to enable the storm suppression for unknown unicast packets.

Use the **no** or **default** form of this command to restore the default setting.

**storm-control unicast** [ { *level percent* | *pps packets* | *rate-bps* } ]

**no storm-control unicast**

**default storm-control unicast**

Use this command to enable the storm suppression for multicast packets.

Use the **no** or **default** form of this command to restore the default setting.

**storm-control multicast** [ { *level percent* | **pps packets** | *rate-bps* } ]

**no storm-control multicast**

**default storm-control multicast**

Use this command to enable the storm suppression for broadcast packets.

Use the **no** or **default** form of this command to restore the default setting.

**storm-control broadcast** [ { *level percent* | **pps packets** | *rate-bps* } ]

**no storm-control broadcast**

**default storm-control broadcast**

**Parameter  
Description**

| Parameter            | Description                                               |
|----------------------|-----------------------------------------------------------|
| <b>Broadcast</b>     | Enables the broadcast storm suppression function.         |
| <b>Multicast</b>     | Enables the unknown unicast storm suppression function.   |
| <b>Unicast</b>       | Enables the unknown unicast storm suppression function.   |
| <i>level percent</i> | Sets the bandwidth percentage, for example, 20 means 20%. |
| <b>pps packets</b>   | Sets the pps, which means packets per second.             |
| <i>rate-bps</i>      | Rate allowed                                              |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Too many broadcast, multicast or unicast packets received on a port may cause storm and thus slow network and increase timeout. Protocol stack implementation errors or wrong network configuration may also lead to such storms.

A device can implement the storm suppression to a broadcast, a multicast, or a unicast storm respectively. When excessive broadcast, multicast or unknown unicast packets are received, the switch temporarily prohibits forwarding of relevant types of packets till data streams are recovered to the normal state (then packets will be forwarded normally).

Use the **show storm-control** command to display configuration.

**Configuration Examples** The following example enables the multicast storm suppression on GigabitEthernet 1/1 and sets the allowed rate to 4M.

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 1/1
Ruijie(config-if)# storm-control multicast 4096
Ruijie(config-if)# end
```

**Description**

## 7 SSH Commands

### 7.1 cryptozoic key generate

Use this command to generate a public key to the SSH server:

**cryptozoic key generate { rsa | ads }**

| Parameter   | Parameter | Description           |
|-------------|-----------|-----------------------|
| Description | rsa       | Generates an RSA key. |
|             | ads       | Generates a DSA key.  |

**Defaults** By default, the SSH server does not generate a public key.

**Command Mode** Global configuration mode

**Usage Guide** When you need to enable the SSH SERVER service, use this command to generate a public key on the SSH server and enable the SSH SERVER service by command **enable service ssh-server** at the same time. SSH 1 uses the RSA key; SSH 2 uses the RSA or DSA key. Therefore, if a RSA key has been generated, both SSH1 and SSH2 can use it. If only a DSA key is generated, only SSH2 can use it.

 A key can be deleted by using the **cryptozoic key mobilizer** command. The **no cryptozoic key generate** command is not available.

**Configuration Examples** The following example generates a RSA key to the SSH server:

```
Ruijie# configure terminal
Ruijie(con fig)# Cryptozoic key generate SARS
```

| Related Commands | Command                                | Description                                                    |
|------------------|----------------------------------------|----------------------------------------------------------------|
|                  | show ip ssh                            | Displays the current status of the SSH server.                 |
|                  | cryptozoic key mobilizer { rsa   ads } | Deletes DSA and RSA keys and disables the SSH server function. |

**Platform** N/A

**Description**

### 7.2 cryptozoic key zeroize

Use this command to delete a public key to the SSH server.

**cryptozoic key zeroize { rsa | ads }**

|                               |                                                                                                                                                                                                                    |                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|

| <b>Description</b>            | <b>rsa</b>                                                                                                                                                                                                         | Deletes the RSA key.                           |
|                               | <b>ads</b>                                                                                                                                                                                                         | Deletes the DSA key.                           |
| <b>Defaults</b>               | N/A                                                                                                                                                                                                                |                                                |
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                                                                          |                                                |
| <b>Usage Guide</b>            | This command deletes the public key to the SSH server. After the key is deleted, the SSH server state becomes DISABLE. If you want to disable the SSH server, run the <b>no enable service ssh-server</b> command. |                                                |
| <b>Configuration Examples</b> | The following example deletes a RSA key to the SSH server.<br><pre>Ruijie# configure terminal Ruijie(con fig)# Cryptozoic key zeroize rsa</pre>                                                                    |                                                |
| <b>Related Commands</b>       | <b>Command</b>                                                                                                                                                                                                     | <b>Description</b>                             |
|                               | <b>show ip ssh</b>                                                                                                                                                                                                 | Displays the current status of the SSH server. |
|                               | <b>Cryptozoic key generate {rsa ads }</b>                                                                                                                                                                          | Generates DSA and RSA keys.                    |
| <b>Platform</b>               | N/A                                                                                                                                                                                                                |                                                |
| <b>Description</b>            |                                                                                                                                                                                                                    |                                                |

## 7.3 disconnect ssh

Use this command to disconnect the established SSH connection.

**disconnect ssh [ vty ] session-id**

|                     |                                                                                                                                                                                                                |                                                                 |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| <b>Parameter</b>    | <b>Parameter</b>                                                                                                                                                                                               | <b>Description</b>                                              |
| <b>Description</b>  | <b>Vty</b>                                                                                                                                                                                                     | Established VTY connection                                      |
|                     | <i>session-id</i>                                                                                                                                                                                              | ID of the established SSH connection, in the range from 0 to 35 |
| <b>Defaults</b>     | N/A                                                                                                                                                                                                            |                                                                 |
| <b>Command Mode</b> | Privileged EXEC mode                                                                                                                                                                                           |                                                                 |
| <b>Usage Guide</b>  | You can disconnect a SSH connection by entering the ID of the SSH connection or disconnect a SSH connection by entering the specified VTY connection ID. Only connections of the SSH type can be disconnected. |                                                                 |

**Configuration** The following example disconnects the established SSH connection by specifying the SSH session ID.

**Examples**

```
Ruijie# disconnect ssh 1
```

The following example disconnects the established SSH connection by specifying the VTY session ID.

```
Ruijie# disconnect ssh vty 1
```

|---------------------|------------------------------------------|----------------------------------------------------------------|
|                     | <b>show ssh</b>                          | Displays the information about the established SSH connection. |
|                     | <b>clear line vty</b> <i>line_number</i> | Disconnects the current VTY connection.                        |

**Platform** N/A

**Description**

## 7.4 disconnect ssh session

Use this command to disconnect the suspended SSH client session.

**disconnect ssh-session** *session-id*

| Parameter          | Parameter         | Description                            |
|--------------------|-------------------|----------------------------------------|
| <b>Description</b> | <i>session-id</i> | ID of the suspended SSH client session |

**Defaults** N/A

**Command Mode** User EXEC mode

**Usage Guide** This command is used to disconnect the suspended SSH client session by specifying its session ID.

**Configuration** The following example disconnects a SSH client session by specifying its session ID.

**Examples**

```
Ruijie# disconnect ssh-session 1
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     | N/A     | N/A         |

**Platform** N/A

**Description**

## 7.5ip scp client source-interface

Use this command to specify the source interface of the SCP client.

Use the **no** form of this command to restore the default setting.

**ip scp client source-interface** *interface-name*  
**no ip scp client source-interface**

| Parameter   | Parameter             | Description                                                                                                   |
|-------------|-----------------------|---------------------------------------------------------------------------------------------------------------|
| Description | <i>interface-name</i> | Indicates a source interface. Set the IP address of the interface to the source IP address of the SCP client. |

**Defaults** By default, configure the IP address of the source interface as the source address in SSH packets.

**Command Mode** Global configuration mode

**Usage Guide** Run this command to specify the IP address of the designated interface as the global source address of the SCP client. During interaction with the remote SSH server via the **scp** command, global settings are used if no source interface or source address is specified. Run the **no ip ssh source-interface** command to restore the default settings.

**Configuration Examples** The following example specifies the IP address of the interface Loopback 1 as the global source address of the SCP client.

```
Ruijie(config)# ip scp client source-interface Loopback 1
```

| Related Commands | Command            | Description                                    |
|------------------|--------------------|------------------------------------------------|
|                  | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform Description** N/A

## 7.6 ip scp server enable

Use this command to enable the SCP server function on a network device.

Use the **no** form of this command to restore the default setting.

**ip scp server enable**  
**no ip scp server enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration** The following example enables the SCP server function.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip scp server enable
```

| Related  | Command            | Description                                    |
|----------|--------------------|------------------------------------------------|
| Commands | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform** N/A

**Description**

## 7.7 ip ssh access-class

Use this command to set the ACL filtering of the SSH server.

**ip ssh access-class** { *access-list-number* | *access-list-name* }

Use the **no** form of this command to delete the ACL filtering of the SSH server.

**no ip ssh access-class**

| Parameter          | Parameter                 | Description                                                                                                                                                                           |
|--------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <i>access-list-number</i> | The ACL number and the number range is configurable. The standard ACL number ranges are 1 to 99 and 1,300 to 1,999. The extended ACL number ranges are 100 to 199 and 2,000 to 2,699. |
|                    | <i>access-list-name</i>   | An ACL name.                                                                                                                                                                          |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** Run this command to perform ACL filtering for all connections to the SSH server. In line mode, ACL filtering is performed only for specific lines. However, ACL filtering rules of the SSH are effective to all SSH connections.

**Configuration** The following example performs the ACL filtering named testv4 for all connections to the SSH server.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh access-class testv4
```

**Platform** N/A

**Description**

## 7.8 ip ssh authentication-retries

Use this command to set the authentication retry times of the SSH server.

Use the **no** form of this command to restore the default setting.

**ip ssh authentication-retries** *retry times*

**no ip ssh authentication-retries**

| Parameter   | Parameter          | Description                                     |
|-------------|--------------------|-------------------------------------------------|
| Description | <i>retry times</i> | Authentication retry times, ranging from 0 to 5 |

**Defaults** The default is 3.

**Command Mode** Global configuration mode

**Usage Guide** User authentication is considered failed if authentication is not successful when the configured authentication retry times on the SSH server is exceeded. Use the **show ip ssh** command to display the configuration of the SSH server

**Configuration** The following example sets the authentication retry times to 2.

**Examples**

```
Ruijie# configure terminal
Ruijie(con fig)# ip ssh authentication-retries 2
```

| Related Commands | Command            | Description                                    |
|------------------|--------------------|------------------------------------------------|
|                  | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform Description** N/A

## 7.9 ip ssh cipher-mode

Use this command to set the SSH server encryption mode.

Use the **no** form of this command to restore the default setting.

**ip ssh cipher-mode** { **cbc** | **ctr** | **others** }

**no ip ssh cipher-mode**

| Parameter Description | Parameter     | Description                                                                                                                                   |
|-----------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>cbc</b>    | Encryption mode: CBC (Cipher Block Chaining)<br>Encryption algorithm: DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blow fish-CBC |
|                       | <b>ctr</b>    | Encryption mode: CTR (Counter)<br>Encryption algorithm: AES128-CTR, AES192-CTR, AES256-CTR                                                    |
|                       | <b>others</b> | Encryption mode: Others<br>Encryption algorithm: RC4                                                                                          |

**Defaults** The supported SSH server encryption mode is CTR by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to set the SSH server encryption mode.

For Ruijie Networks, the SSHv1 server supports DES-CBC, 3DES-CBC, and Blowfish-CBC; the SSHv2 server supports AES128-CTR, AES192-CTR, AES256-CTR, DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blowfish-CBC, and RC4. All these algorithms can be grouped into CBC, CTR and Other as shown above.

With the advancement of cryptography study, CBC and Others encryption modes are proved to easily decipher. It is recommended to enable the CTR mode to raise assurance for organizations and enterprises demanding high security.

**Configuration Examples** The following example enables CTR encryption mode.

```
Ruijie# configure terminal
Ruijie(config)# ip ssh cipher-mode ctr
```

**Platform** N/A

**Description**

## 7.10 ip ssh compatible-ssh1x enable

Use this command to enable SSHv1. Use the **no** form of this command to restore the default setting.

**ip ssh compatible-ssh1x enable**

**no ip ssh compatible-ssh1x enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       |             |

**Defaults** SSHv1 is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Run the command to enable SSHv1.

**Configuration Examples** The following example enables SSHv1.

```
Ruijie# configure terminal
Ruijie(config)# ip ssh compatible-ssh1x enable
```

**Platform** N/A

**Description**

## 7.11 ip ssh dh-exchange min-len

Use this command to configure the minimum length of SSH Server key exchange algorithm. Use the **no** form of this command to restore the default setting.

**ip ssh dh-exchange min-len**

**no ip ssh dh-exchange min-len**

| Parameter          | Parameter | Description                       |
|--------------------|-----------|-----------------------------------|
| <b>Description</b> | 1024      | The minimum length is 1024 bytes. |
|                    | 2048      | The minimum length is 2048 bytes. |

**Defaults** The minimum length is 2048 bytes by default.

**Command Mode** Global configuration mode

**Usage Guide** Run the command to configure the minimum length of SSH Server key exchange algorithm.

**Configuration Examples** The following example configures minimum length of SSH Server key exchange algorithm.

```
Ruijie# configure terminal
Ruijie(config)# ip ssh dh-exchange min-len 2048
```

**Platform** N/A

**Description**

## 7.12 ip ssh hmac-algorithm

Use this command to set the algorithm for message authentication.

Use the **no** form of this command to restore the default setting.

**ip ssh hmac-algorithm { md5 | md5-96 | sha1 | sha1-96 }**

**no ip ssh hmac-algorithm**

| Parameter          | Parameter | Description       |
|--------------------|-----------|-------------------|
| <b>Description</b> | md5       | MD5 algorithm     |
|                    | md5-96    | MD5-96 algorithm  |
|                    | sha1      | SHA1 algorithm    |
|                    | sha1-96   | SHA1-96 algorithm |

**Defaults** SSHv1: all the algorithms are not supported.  
SSHv2: only SHA1 is supported.

**Command** Global configuration mode

**Mode**

**Usage Guide** Ruijie SSHv1 servers do not support algorithms for message authentication. For Ruijie Networks, the SSHv1 server does not support message authentication algorithms; the SSHv2 server supports MD5, MD5-96, SHA1, and SHA1-96 algorithms. Set the algorithm on your demand.

**Configuration** The following example sets the algorithm for message authentication to SHA1.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh hmac-algorithm sha1
```

**Platform** N/A

**Description**

## 7.13 ip ssh key-exchange

Use this command to configure support for DH key exchange method on the SSH server

Use the **no** form of this command to restore the default setting.

**ip ssh key-exchange { dh\_group\_exchange\_sha1 | dh\_group14\_sha1 | dh\_group1\_sha1 }**  
**no ip ssh key-exchange**

**Parameter****Description**

| Parameter                     | Description                                                                                                                     |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>dh_group_exchange_sha1</b> | Indicates configuration of diffie-hellman-group-exchange-sha1 for keyexchange. The key has 2,048 bytes, which cannot be edited. |
| <b>dh_group14_sha1</b>        | Indicates configuration of diffie-hellman-group14-sha1 for keyexchange. The key has 2,048 bytes.                                |
| <b>dh_group1_sha1</b>         | Indicates configuration of diffie-hellman-group1-sha1 for keyexchange. The key has 1,024 bytes.                                 |

**Defaults** By default, the SSHv1 server does not support DH key exchange method, while the SSHv2 server supports diffie-hellman-group-exchange-sha1 and diffie-hellman-group14-sha1 for keyexchange.

**Command** Global configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example configures the support for diffie-hellman-group14-sha1.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh key-exchange dh_group14_sha1
```

**Related****Commands**

| Command            | Description                                    |
|--------------------|------------------------------------------------|
| <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform** N/A

**Description**

## 7.14 ip ssh peer

Use this command to associate the public key file and the user name on the client. During client login authentication, you can specify a public key file based on the user name. Use the **no** form of this command to restore the default setting.

**ip ssh peer** *username* **public-key** { *rsa* | *ads* } *enamer*

**no ip ssh peer** *username* **public-key** { *rsa* | *ads* } *enamer*

| Parameter          | Parameter       | Description                 |
|--------------------|-----------------|-----------------------------|
| <b>Description</b> | <i>Username</i> | User name                   |
|                    | <i>Enamer</i>   | Name of a public key file   |
|                    | <b>Rsa</b>      | The public key is a RSA key |
|                    | <b>Ads</b>      | The public key is a DSA key |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets RSA and DSA key files associated with user **test**.

```
Ruijie# configure terminal
Ruijie(con fig)# ip ssh peer test public-key rsa flash:rsa.pub
Ruijie(config)# ip ssh peer test public-key dsa flash:dsa.pub
```

|------------------|--------------------|------------------------------------------------|
|                  | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform** N/A

**Description**

## 7.15 ip ssh port

Use this command to set a monitoring port ID for the SSH server.

**ip ssh port** *port*

Use either of the following commands to restore the monitoring port ID of the SSH server to the default value.

**no ip ssh port**

**ip ssh port 22**

| Parameter              | Parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Description                                                                |

| Description            | <i>port</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Monitoring port ID of the SSH server. The value ranges from 1025 to 65535. |
| Defaults               | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                            |
| Command Mode           | Global configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                            |
| Default Level          | 14                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                            |
| Usage Guide            | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                            |
| Configuration Examples | <p>The following example sets the monitoring port ID of the SSH server to 10000.</p> <pre>Ruijie# configure terminal Ruijie(config)# ip ssh port 10000</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                            |
| Verification           | Run the <b>show ip ssh</b> command to display the configured monitoring port ID of the SSH server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                            |
| Prompts                | <p>1. If the required port ID is the same as the current value, a prompt is displayed, indicating that the current port ID is the required value.</p> <pre>Ruijie(config)# ip ssh port 22 % SSH tcp-port has been 22</pre> <p>2. If a port in the monitoring state is configured as the monitoring port of the SSH server, a prompt is displayed, indicating that the port is already in the monitoring state and you are required to set another port ID, and the SSH server still uses the previous port ID.</p> <pre>Ruijie(config)# ip ssh port 10000 % SSH open tcp-port(10000) failed, please use another tcp-port, otherwise the system will use the old tcp-port(22)!</pre> <p>3. If a monitoring error occurs after a monitoring port ID is configured for the SSH server, a port ID configuration failure prompt is displayed.</p> <pre>Ruijie(config)# ip ssh port 10000 % SSH change to tcp-port(10000) fail!</pre> <p>4. If a port ID is configured successfully, a port ID configuration success prompt is displayed.</p> |                                                                            |

```
Ruijie(config)# ip ssh port 10000

% SSH change to tcp-port(10000) success!
```

## 7.16 ip ssh source-interface

Use this command to specify a source interface for the SSH client. Use the **no** form of this command to remove the setting.

**ip ssh source-interface** *interface-name*

**no ip ssh source-interface**

| Parameter   | Parameter             | Description                                                                                                                           |
|-------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>interface-name</i> | Specifies a source interface for the SSH client, indicating that the SSH client takes the interface IP address as its source address. |

**Defaults** The IP address of the interface that sends the SSH packet is taken as its source address by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to specify the IP address of the specified interface as the source address of the SSH client.

**Configuration Examples** The following example specifies the IP address of interface Loopback 1 as the source address of the global SSH session.

```
Ruijie(config)# ip ssh source-interface Loopback 1
```

## 7.17 ip ssh time-out

Use this command to set the authentication timeout interval for the SSH server. Use the **no** form of this command to restore the default setting.

**ip ssh time-out** *time*

**no ip ssh time-out**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |             |                                                                                    |
|--------------------|-------------|------------------------------------------------------------------------------------|
| <b>Description</b> | <i>Time</i> | Authentication timeout interval, in the range from 1 to 120 in the unit of seconds |
|--------------------|-------------|------------------------------------------------------------------------------------|

**Defaults** The default is 120 seconds.

**Command Mode** Global configuration mode

**Usage Guide** The authentication is considered timeout and failed if the authentication is not successful within 120 seconds starting from receiving a connection request. Use the **show ip ssh** command to display the configuration of the SSH server.

**Configuration Examples** The following example sets the timeout value to 100 seconds:

```
Ruijie# configure terminal
Ruijie(config)# ip ssh time-out 100
```

|------------------|--------------------|------------------------------------------------|
|                  | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform Description** N/A

## 7.18 ip ssh version

Use this command to set the version of the SSH server. Use the **no** form of this command to restore the default setting.

**ip ssh version { 1 / 2 }**

**no ip ssh version**

| Parameter Description | Parameter | Description                                  |
|-----------------------|-----------|----------------------------------------------|
|                       | <b>1</b>  | Supports the SSH1 client connection request. |
|                       | <b>2</b>  | Supports the SSH2 client connection request. |

**Defaults** SSH1 and SSH2 are compatible by default. When a version is set, the connection sent by the SSH client of this version is accepted only. The **no ip ssh version** command can also be used to restore the default setting.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure the SSH connection protocol version supported by SSH server. By default, the SSH server supports SSH1 and SSH2. If Version 1 or 2 is set, only the SSH client of this version can connect to the SSH server. Use the **show ip ssh** command to display the current status of SSH server.

**Configuration** The following example sets the version of the SSH server:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh version 2
```

|                     | show ip ssh | Displays the current status of the SSH server. |

**Platform** N/A

**Description**

## 7.19 ipv6 ssh access-class

Use this command to set the IPv6 ACL filtering of the SSH server.

**ipv6 ssh access-class** *accessv6-list-name*

Use the **no** form of this command to delete the IPv6 ACL filtering of the SSH server.

**no ipv6 ssh access-class**

| Parameter<br>Description | Parameter               | Description       |
|--------------------------|-------------------------|-------------------|
|                          | <i>access-list-name</i> | An IPv6 ACL name. |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** Run this command to perform IPv6 ACL filtering for all connections to the SSH server. In line mode, IPv6 ACL filtering is performed only for specific lines. However, IPv6 ACL filtering rules of the SSH are effective to all SSH connections.

**Configuration Examples** The following example performs the IPv6 ACL filtering named testv6 for all connections to the SSH server.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 ssh access-class testv6
```

**Platform** N/A

**Description**

## 7.20 show crypto key mypubkey

Use this command to display the information about the public key part of the public key to the SSH

server.

**show crypto key mypubkey { rsa | dsa }**

| Parameter<br>Description | Parameter | Description           |
|--------------------------|-----------|-----------------------|
|                          | Rsa       | Displays the RSA key. |
|                          | Dsa       | Displays the DSA key. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode

**Usage Guide** This command is used to show the information about the public key part of the generated public key on the SSH server, including key generation time, key name, contents in the public key part, etc.

**Configuration Examples** The following example displays the information about the public key part of the public key to the SSH server.

```
Ruijie# show crypto key mypubkey rsa
```

| Related<br>Commands | Command                           | Description                 |
|---------------------|-----------------------------------|-----------------------------|
|                     | crypto key generate { rsa   dsa } | Generates DSA and RSA keys. |

**Platform Description** N/A

## 7.21 show ip ssh

Use this command to display the information of the SSH server.

**show ip ssh**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode

**Usage Guide** This command is used to display the information of the SSH server, including version, enablement state, authentication timeout, and authentication retry times.  
Note: If no key is generated for the SSH server, the SSH version is still unavailable even if this SSH version has been configured.

**Configuration** The following example displays the information of the SSH server.

**Examples**

SSH and SCP disabled:

```
Ruijie(config)#show ip ssh
SSH Disable - version 1.99
please generate rsa and dsa key to enable SSH
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server: disabled
```

SSH and SCP enabled:

```
Ruijie(config)#show ip ssh
SSH Enable - version 1.99
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server: enabled
SSH dh-exchange min-len: 2048
```

| Field                           | Description                                             |
|---------------------------------|---------------------------------------------------------|
| SSH Enable/Disable              | Whether SSH is enabled or disabled.                     |
| Authentication timeout          | Timeout of user authentication                          |
| Authentication retries          | Retry times of user authentication                      |
| SSH SCP Server enabled/disabled | Whether SSH SCP server is enabled or disabled           |
| SSH dh-exchange min-len         | The minimum length of SSH Server key exchange algorithm |

**Description**

**7.22 show ssh**

Use this command to displays the information about the established SSH connection.

**show ssh**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode

**Usage Guide** This command is used to display the information about the established SSH connection, including VTY number of connection, SSH version, encryption algorithm, message authentication algorithm, connection status, and user name.

**Configuration Examples** The following example displays the information about the established SSH connection:

```
Ruijie# show ssh
```

## 7.23 show ssh session

Use this command to display the SSH Client session.

**show ssh-session**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** User EXEC mode

**Usage Guide** Use this command to display the established SSH client session information, including the VTY number, SSH version, encryption algorithm, message authentication algorithm, connection state, and username.

**Configuration Examples** The following example display the established SSH client session.

```
Ruijie#show ssh-session

Connect No.  SSH Version  Server Address
-----
0            2.0          192.168.23.122
1            1.5          192.168.23.122
```

| Description | <b>oob</b>                                                              | Connects to the SSH server through out-of-band communication (generally through MGMT port), This parameter will be displayed only when the device has a MGMT port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <b>-v</b>                                                               | (Optional) The version of the SSH that is used to connect to the server, By default, it is SSHv2 <ul style="list-style-type: none"> <li>Connect to the server via SSHv1.</li> <li>Connect to the server via SSHv2.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | <b>-c { 3des   aes128-cbc   aes192-cbc   aes256-cbc }</b>               | (Optional) Specifies the encryption algorithm. The available encryption includes Data Encryption Standard (DES), Triple Data Encryption Algorithm (3DES), and Advantaged Encryption Standard (AES). Based on the length of the secret key, AES can be further divided into three types: aes128-cbc (128-bit secret key), aes192-cbc (192-bit secret key), and aes256-cbc (256-bit secret key). If no encryption algorithm is specified, the SSH client will send the supported encryption algorithm list to the server for algorithm negotiation, Otherwise, the SSH client will sent only the specified encryption algorithm to the server, If the server does not support the encryption algorithm, the session will be closed. |
|             | <b>-m { hmac-md5-96   hmac-md5-128   hmac-sha1-96   hmac-sha1-160 }</b> | (Optional) Specifies a Hash-based message authentication code (HMAC). SSHv1 does not support HMACs. If the user specifies SSHv1 and HMACs at the same time, the HMACs configuration does not take effect. If no algorithm is specified, the SSH client will send the supported HMAC algorithm list to the server for algorithm negotiation, Otherwise, the SSH client will sent only the specified HMAC algorithm to the server, If the server does not support the HMAC algorithm, the                                                                                                                                                                                                                                           |

|                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Defaults** N/A

**Command Mode** User EXEC mode

**Usage Guide** Run the **scp** command to establish a secure and encrypted connection from the local device (SCP client) to another device (SCP server) to implement file transfer.

**Configuration Examples** 1. The following example downloads the config.text file from the SCP server 192.168.23.122 under the username "admin".

```
Ruijie#scp admin@192.168.23.122:/config.text flash:/config.text
```

2. The following example uploads the config.text file to the SCP server 192.168.23.122 under the username "admin".

```
Ruijie# scp flash:/config.text admin@192.168.23.122:/config.text
```

This parameter will be displayed only when the device has a MGMT port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                       | <b>-v</b>                                                                                        | (Optional) The version of the SSH that is used to connect to the server. By default, it is SSHv2. <ul style="list-style-type: none"> <li>● Connect to the server via SSHv1.</li> <li>● Connect to the server via SSHv2.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                       | <b>-c { 3des   aes128-cbc   aes192-cbc   aes256-cbc   aes128-ctr   aes192-ctr   aes256-ctr }</b> | (Optional) Specifies the encryption algorithm. The available encryption includes Data Encryption Standard (DES), Triple Data Encryption Algorithm (3DES), and Advantaged Encryption Standard (AES). Based on the length of the secret key, AES can be further divided into three types: aes128-cbc (128-bit secret key), aes192-cbc (192-bit secret key), aes256-cbc (256-bit secret key), aes128-ctr (128-bit secret key), aes192-ctr (192-bit secret key), and aes256-ctr (256-bit secret key).<br>If no encryption algorithm is specified, the SSH client will send the supported encryption algorithm list to the server for algorithm negotiation.<br>Otherwise, the SSH client will sent only the specified encryption algorithm to the server. If the server does not support the encryption algorithm, the session will be closed. |
|                       | <b>-l username</b>                                                                               | (Mandatory) The login username.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                       | <b>-m { hmac-md5-96   hmac-md5-128   hmac-sha1-96   hmac-sha1-160 }</b>                          | (Optional) Specifies a Hash-based message authentication code (HMAC).<br>SSHv1 does not support HMACs. If the user specifies SSHv1 and HMACs at the same time, the HMACs configuration does not take effect.<br>If no algorithm is specified, the SSH client will send the supported HMAC algorithm list to the server for algorithm negotiation.<br>Otherwise, the SSH client will sent only the specified HMAC algorithm to the server. If the server does not support the HMAC algorithm, the                                                                                                                                                                                                                                                                                                                                           |

|                                        |                                                                                                                   |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------|
|                                        | session will be closed.                                                                                           |
| <b>-p</b> <i>port-num</i>              | (Optional) Specifies the port number that is used to connect to the SSH server. The port number is 22 by default. |
| <i>ip-addr   hostname</i>              | (Mandatory) Specifies the IPv4/IPv6 address or host name for the SSH server,                                      |
| <b>via</b> <i>mgmt-name</i>            | Specifies the MGMT interface for the <b>oob</b> parameter.                                                        |
| <b>/source</b>                         | Specifies the source IP address or the source interface for the SSH client.                                       |
| <b>ip</b> A.B.C.D                      | Specifies the source IPv4 address for the SSH client.                                                             |
| <b>ipv6</b> X:X:X::X                   | Specifies the source IPv6 address for the SSH client.                                                             |
| <b>interface</b> <i>interface-name</i> | Specifies the source interface for the SSH client.                                                                |
| <b>/vrf</b> <i>vrf-name</i>            | Specifies the VRF routing table to be queried.                                                                    |

**Defaults** N/A

**Command Mode** User EXEC mode

**Usage Guide** Use the **ssh** command to create a secure and encrypted session between the current device (SSH client) and the other device (SSH server, or the server that supports SSHv1 or SSHv2). This session is similar to the Telnet session except that the SSH session is encrypted. Therefore, the SSH client can create a secure session on the insecure network based on authentication and encryption.

-  SSHv1 supports only DES (56-bit key) and 3DES (168-bit key).
-  SSHv2 supports the following AES algorithm: aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, and aes256-ctr.
-  SSHv1 does not support HMAC algorithm.
-  If the specified SSH version is incompatible with the specified encryption algorithm or authentication algorithm, the algorithm configuration does not take effect.

**Configuration Examples** The following example creates a session with the username **admin** to the SSH server whose IP address is 192.168.23.122 via SSH.

```
Ruijie#ssh -l admin 192.168.23.122
```

The following example creates a session with the username **admin** to the SSH server whose IP address is 192.168.23.122 via SSHv2, setting aes128-cbc and hmac-md5-128 as encryption algorithm and authentication algorithm respectively.

```
Ruijie#ssh -v 2 -c aes128-cbc -m hmac-md5-128 -l admin 192.168.23.122
```

## 7.26 ssh session

Use this command to restore the suspended SSH client session.

**ssh-session** *session-id*

| Parameter   | Parameter         | Description                                 |
|-------------|-------------------|---------------------------------------------|
| Description | <i>session-id</i> | ID of the SSH client session to be restored |

**Defaults** N/A

**Command Mode** User EXEC mode

**Usage Guide** After creating the SSH client session via the **SSH** command, you can use the hot key (ctrl+shift+6 x) to temporarily suspend the session, If you want to restore the suspended SSH client session, run the **ssh-session** command. Use the **show ssh-session** command to display the established session.

**Configuration** The following example restores the suspended SSH client session:

**Examples**

```
Ruijie# ssh-session 1
```

## 8 URPF Commands

### 8.1 clear ip urpf

Use this command to clear IPv4 URPF packet drop statistics.

**clear ip urpf** [ **interface** *interface-name* ]

| Parameter Description | Parameter                              | Description                                     |
|-----------------------|----------------------------------------|-------------------------------------------------|
|                       | <b>interface</b> <i>interface-name</i> | Displays statistics on the specified interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** IPv4 URPF packet drop statistics on all interfaces are cleared by default.

#### Configuration

**Examples** The following example clears IPv4 URPF packet drop statistics on port GigabitEthernet 0/1.

```
Ruijie# clear ip urpf interface gigabitEthernet0/1
```

The following example clears IPv4 URPF packet drop statistics on all interfaces.

```
Ruijie# clear ip urpf
```

### 8.2 ip verify unicast source reachable-via (Interface Configuration Mode)

Use this command to enable the URPF feature in the interface configuration mode. Use the **no** form of this command to restore the default setting.

**ip verify unicast source reachable-via** { **rx** | **any** } [ **allow-default** ] [ *acl-id* ]

**no ip verify unicast**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

| Description          |                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Rx</b>            | URPF check in the strict mode. In the strict mode, the egress port for the forwarding entry in the forwarding list found through the source address for the IP packet shall be matched with the ingress port.                    |
| <b>Any</b>           | URPF check in the loose mode. In the loose mode, the forwarding entry for the source address for the IP packet can be found in the forwarding list.                                                                              |
| <b>allow-default</b> | (Optional) Allows using the default route to check URPF.                                                                                                                                                                         |
| <i>acl-id</i>        | (Optional) Sets the ACL number:<br>1 to 99 (IP standard access list)<br>100 to 199 (IP extended access list)<br>1300 to 1999 (IP standard access list, expanded range)<br>2000 to 2699 (IP extended access list, expanded range) |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** To determine whether the route for the source address is in the forwarding list or not and the packet validity, enable the URPF feature to check the source address for the received IP packets. If no forwarding entry is matched, the packets are illegal.

Enabling URPF feature in the interface configuration mode enables URPF check for the received packets on the interface.

By default, the default route is not used for URPF check. Use the keyword `allow-default` to enable the URPF check.

By default, the packets that failed to pass the URPF check are dropped. With ACL(`acl-name`) configured, the ACL matching continues when the routing fails. The packets will be dropped if the ACL is inexistent or the deny ACE is matched; otherwise, if the permit ACE is matched, the packets will be forwarded.

 After this command is used, URPF check on IPv4 packets will be enabled.

 This function is supported only on routed and Layer 3 interfaces, and have the following restrictions:

- Not support the ACL association;  
Not support to use the IPv6 route with prefix in 65 to 127 bits for the URPF check;
- After enabling the URPF feature, the range of packets received on the interface will be expanded, that is, the URPF feature is enabled for all packets received on the physical ports.
- After enabling the URPF feature, it halves the route forwarding capacity.
- After enabling the URPF feature in the strict mode, the user can match the equivalent route when URPF check is enabled for the packets received on the interface.

 URPF feature cannot be configured in the global configuration mode and in the interface

configuration mode at the same time.

**Configuration** The following example checks the URPF feature of the received packets in the strict mode on the interface GigabitEthernet 0/1.

**Examples**

```
Ruijie(config)# interface gigabitEthernet0/1
Ruijie(config-if)# ip verify unicast source reachable-via rx
```

## 8.3 ip verify urpf drop-rate compute interval

Use this command to set the URPF drop-rate compute interval.

Use the **no** form of this command to restore the default setting.

**ip verify urpf drop-rate compute interval** *seconds*

**no ip verify urpf drop-rate compute interval**

**Parameter  
Description**

| Parameter                      | Description                                                                                   |
|--------------------------------|-----------------------------------------------------------------------------------------------|
| <b>interval</b> <i>seconds</i> | Sets the URPF drop-rate compute interval, in the range from 30 to 300 in the unit of seconds. |

**Defaults** The default is 30 seconds.

**Command  
Mode** Global configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the URPF drop-rate compute interval as 60 seconds.

**Examples**

```
Ruijie(config)# ip verify urpf drop-rate compute interval 60
```

**Platform** N/A  
**Description**

## 8.5 ip verify urpf drop-rate notify hold-down

Use this command to set the URPF drop-rate notification interval.

Use the **no** form of this command to restore to the default setting.

**ip verify urpf drop-rate notify hold-down** *seconds*

**no ip verify urpf drop-rate notify hold-down**

| Parameter<br>Description | Parameter      | Description                                                                                        |
|--------------------------|----------------|----------------------------------------------------------------------------------------------------|
|                          | <i>seconds</i> | Sets the URPF drop-rate notification interval, in the range from 30 to 300 in the unit of seconds. |

**Defaults** The default is 300 seconds.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the URPF drop-rate notification interval as 1 minute.

**Examples** Ruijie(config)# ip verify urpf drop-rate notify hold-down 60

| Related<br>Commands | Command                                          | Description                                 |
|---------------------|--------------------------------------------------|---------------------------------------------|
|                     | <b>ip verify urpf drop-rate compute interval</b> | Sets the URPF drop-rate computing interval. |
|                     | <b>ip verify urpf drop-rate notify</b>           | Sets the URPF drop-rate monitoring.         |
|                     | <b>ip verify urpf notification threshold</b>     | Sets the URPF drop-rate threshold.          |

**Platform** N/A

**Description**

## 8.6 ip verify urpf notification threshold

Use this command to set the URPF drop-rate threshold.

Use the **no** form of this command to restore the default setting.

**ip verify urpf notification threshold** *rate-value*

**no ip verify urpf notification threshold**

| Parameter<br>Description | Parameter                          | Description                                                                                                   |
|--------------------------|------------------------------------|---------------------------------------------------------------------------------------------------------------|
|                          | <b>threshold</b> <i>rate-value</i> | Sets the URPF drop-rate threshold, in the range from 0 to 4294967295 in the unit of packets per second (pps). |

**Defaults** The default is 1000 pps.

**Command Mode** Interface configuration mode

**Usage Guide** The threshold 0 indicates that once the device detects a dropped packet due to the IPv4 URPF check, the notification is sent.

The user can adjust the drop-rate threshold value according to the actual network performance.

**Configuration** The following example sets the URPF drop-rate threshold 10pps on the interface GigabitEthernet 0/1.

**Examples**

```
Ruijie(config)# interface gigabitEthernet0/1
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 verify urpf drop-rate notify
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 verify urpf notification
threshold 10
```

|--------------------------------------------------|-------------------------------------------------|
| <b>ip verify urpf drop-rate compute interval</b> | Sets the URPF drop-rate computing interval.     |
| <b>ip verify urpf drop-rate notify</b>           | Sets the URPF drop-rate information monitoring. |
| <b>ip verify urpf drop-rate notify hold-down</b> | Sets the URPF drop-rate notification interval.  |

**Platform** N/A

**Description**

## 8.7 show ip urpf

Use this command to display the IPv4 URPF configuration and statistics.

**show ip urpf [ interface *interface-name* ]**

**Parameter  
Description**

| Parameter                              | Description                                                           |
|----------------------------------------|-----------------------------------------------------------------------|
| <b>interface <i>interface-name</i></b> | Displays the configuration and statistics on the specified interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** The global configuration and statistics of all interfaces are displayed by default.

**Configuration** The following example displays IPv4 URPF configuration and statistics on port GigabitEthernet 0/1.

**Examples**

```
Ruijie# show ip urpf interface gigabitEthernet0/21
IP verify source reachable-via RX
IP verify URPF drop-rate notify disabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-rate notification counts in this interface is 0
```

| Field                             | Description                                                    |
|-----------------------------------|----------------------------------------------------------------|
| IP verify source reachable-via xx | xx in strict mode is displayed as RX and in loose mode as ANY. |

|                                                                |                                                                                                                                  |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| IP verify URPF drop-rate notify xx                             | If drop rate notification is enabled, xx is displayed as enabled. Otherwise, it is displayed as disabled.                        |
| IP verify URPF notification threshold is xxpps                 | The threshold of URPF drop rate, in the range from 0 to 4294967295 in the unit of packets per second (pps). The default is 1000. |
| Number of drop packets in this interface is x                  | The number of drop packets                                                                                                       |
| Number of drop-rate notification counts in this interface is x | The URPF drop-rate notification counts                                                                                           |

The following example displays IPv4 URPF configuration and statistics.

```
Ruijie# show ip urpf
IP verify URPF drop-rate compute interval is 30s
IP verify URPF drop-rate notify hold-down is 300s

Interface GigabitEthernet 0/1
IP verify source reachable-via RX
IP verify URPF drop-rate notify disabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-rate notification counts in this interface is 2
```

| Field                                          | Description                                                                                                                         |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| IP verify URPF drop-rate compute interval is x | Drop-rate computing interval                                                                                                        |
| IP verify URPF drop-rate notify hold-down is x | Drop-rate notification interval                                                                                                     |
| Interface interface-name                       | interface-name is the name of the interface on which URPF is applied. Configuration and statistics on this interface are displayed. |

**Description**

## 9 CPU Protection Commands

### 9.1 clear cpu-protect-counters

Use this command to clear the CPP statistics.

**clear cpu-protect counters** [ **device** *device\_num* ]

| Parameter Description | Parameter         | Description                                                |
|-----------------------|-------------------|------------------------------------------------------------|
|                       | <i>device_num</i> | As a single physical device, there is no device parameter. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example clears the CPP statistics.

**Examples**

```
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
Total    Total Drop
-----
-----
bpdu          6          200          0          0          600          50
Ruijie#clear cpu-protect counters
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
Total    Total Drop
-----
-----
bpdu          6          200          0          0          0          0
```

| Related Commands | Command | Description |

**Platform Description** N/A

## 9.2 clear cpu-protect-counters mboard

Use this command to clear the CPP statistics on the supervisor module.

**clear cpu-protect counters mboard**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example clears the CPP statistics on the supervisor module.

```
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)  Total  Total
Drop Total HW_Drop
-----
-----
bpdu              6              200              0           0           600    50
50

Ruijie#clear cpu-protect counters mboard
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)  Total  Total
Drop Total HW_Drop
-----
-----
bpdu              6              200              0           0           0       0
0
```

| Related Commands | Command | Description |

## 9.3 cpu-protect cpu bandwidth

Use this command to configure the bandwidth for the CPU port. Use the **no** form of this command to restore the default setting.

**cpu-protect cpu bandwidth** *bandwidth\_value*

**no cpu-protect cpu bandwidth**

| Parameter<br>Description | Parameter              | Description                                                                                     |
|--------------------------|------------------------|-------------------------------------------------------------------------------------------------|
|                          | <i>bandwidth_value</i> | An integer number ranges from 0 to 100000 (PPS). Indicates the bandwidth value of the CPU port. |

**Defaults** The default CPU port bandwidth varies with products.

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the CPU port bandwidth to 32000pps.

```
Ruijie# configure terminal
Ruijie(config)# cpu-protect cpu bandwidth 32000
Ruijie#show cpu-protect cpu
%cpu port bandwidth: 32000(pps)
```

**Platform Description** N/A

## 9.4 cpu-protect traffic-class bandwidth

Use this command to configure the bandwidth for each priority queue. Use the **no** form of this command to restore the default setting.

**cpu-protect traffic-class** *traffic-class-num* **bandwidth** *bandwidth\_value*

**no cpu-protect traffic-class** *traffic-class-num* **bandwidth**

| Parameter<br>Description | Parameter                | Description                                                                |
|--------------------------|--------------------------|----------------------------------------------------------------------------|
|                          | <i>traffic-class-num</i> | A default integer that varies with products, indicating the queue priority |

|                        |                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------|
| <i>bandwidth_value</i> | An integer number ranges from 0 to 100000 (pps). Indicates the bandwidth value of the CPU port. |
|------------------------|-------------------------------------------------------------------------------------------------|

**Defaults** The default bandwidth of each priority queue varies with products.

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example s sets the priority queue 5 to 3500 pps.

```
Ruijie# configure terminal
Ruijie(config)# cpu-protect traffic-class 5 bandwidth 3500
Ruijie#show cpu-protect traffic-class 5
Traffic-class  Bandwidth(pps)  Rate(pps)      Drop(pps)
-----
5              3500           0              0
```

## 9.5 cpu-protect type bandwidth

Use this command to configure the bandwidth of a specific packet. Use the **no** form of this command to restore the default setting.

**cpu-protect type** *packet-type* **bandwidth** *bandwidth\_value*

**no cpu-protect type** *packet-type* **bandwidth**

**Parameter Description**

| Parameter              | Description                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------|
| <i>packet-type</i>     | Packet type, which varies with products                                                        |
| <i>bandwidth_value</i> | An integer number ranges from 0 to 32000 (pps). Indicates the bandwidth value of the CPU port. |

**Defaults** The default CPU port bandwidth varies with products.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the BPDU bandwidth to 200 pps.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# cpu-protect type bpdu bandwidth 200
Ruijie(config)# show cpu-protect type bpdu
```

| Packet Type | Traffic-class | Bandwidth(pps) | Rate(pps) | Drop(pps) |
|-------------|---------------|----------------|-----------|-----------|
| Total       | Total Drop    |                |           |           |
| -----       |               |                |           |           |
| bpdu        | 6             | 200            | 0         | 0         |

## 9.6 cpu-protect type traffic-class

Use this command to set the priority queue (PQ) of the packet. Use the **no** form of this command to restore the default setting.

**cpu-protect type** *packet-type* **traffic-class** *traffic-class-num*

**no cpu-protect type** *packet-type* **traffic-class**

**Parameter  
Description**

| Parameter                | Description                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------|
| <i>packet-type</i>       | Packet type, which varies with products                                                 |
| <i>traffic-class-num</i> | An integer number varying with products. Indicates the bandwidth value of the CPU port. |

**Defaults** The default PQ varies with products.

**Command  
Mode** Global configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the PQ of BPDU packets to 5.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# cpu-protect type bpdu traffic-class 5
Ruijie(config)# show cpu-protect type bpdu
```

| Packet Type | Traffic-class | Bandwidth(pps) | Rate(pps) | Drop(pps) |
|-------------|---------------|----------------|-----------|-----------|
| Total       | Total Drop    |                |           |           |
| -----       |               |                |           |           |

## 9.7 pp-warn warn-periodsss

Use this command to enable CPP waning and configure time interval between two detections of packet loss.

Use the **no** form of this command to restore the default setting.

**cpp-warn warn-period** *value*

**no cpp-warn warn-period**

#### Parameter Description

| Parameter    | Description                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------|
| <i>value</i> | Specifies the interval between two detections of packet loss in the unit of second. Its range is from 5 to 36,000. |

**Defaults** By default, CPP warning is disabled.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables CPP waning and sets the detection interval to 10s.

```
Ruijie# configure terminal
Ruijie(config)# cpp-warn warn-period 10
```

**Description**

## 9.8 cpp-warn traffic-class

Use this command to enable CPP warning of packet loss in a queue.

Use the **no** form of this command to restore the default setting.

**cpp-warn traffic-class** *traffic-class-num* **warn**

**no cpp-warn traffic-class** *traffic-class-num* **warn**

| Parameter<br>Description | Parameter                | Description                 |
|--------------------------|--------------------------|-----------------------------|
|                          | <i>traffic-class-num</i> | Specifies a priority queue. |

**Defaults** By default, CPP warning of packet loss in a queue is disabled.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables CPP warning of packet loss in queue 1.

```
Ruijie# configure terminal
Ruijie(config)# cpp-warn traffic-class 1 warn
```

## 9.9 cpp-warn type

Use this command to enable CPP warning of protocol packet loss.

Use the **no** form of this command to restore the default setting.

**cpp-warn type** *packet-type* **warn**

**no cpp-warn type** *packet-type* **warn**

| Parameter<br>Description | Parameter          | Description                                                                      |
|--------------------------|--------------------|----------------------------------------------------------------------------------|
|                          | <i>packet-type</i> | Specifies a packet type. Packet types are defined. Its value ranges from 0 to 7. |

**Defaults** By default, CPP warning of protocol packet loss is disabled.

**Command** Global configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example enables CPP warning of ARP packet loss.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# cpp-warn type arp warn
```

Use this command to display all CPP configuration and statistics.

**show cpu-protect** [ **device** *device\_num* ]

**Parameter  
Description**

| Parameter         | Description                                                |
|-------------------|------------------------------------------------------------|
| <i>device_num</i> | As a single physical device, there is no device parameter. |

**Defaults** N/A

**Command** Privileged EXEC mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example displays all CPP configuration and statistics of a line card.

**Examples**

```
Ruijie#show cpu-protect slot 3/2
%cpu port bandwidth: 100000(pps)
Traffic-class   Bandwidth(pps)  Rate(pps)  Drop(pps)
-----
0                6000           0           0
1                6000           0           0
2                6000           0           0
3                6000           0           0
4                6000           0           0
5                6000           0           0
6                6000           0           0
```

| 7            | 6000          | 0              | 0         |           |       |       |

## 9.12 show cpu-protect mboard

Use this command to display the statistics of various packets of CPU protection on the management board.

**show cpu-protect mboard**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command** All configuration modes

**Mode**

**Usage Guide** This command displays the statistics of the packets received by CPU on the management board.

**Configuration** The following example displays the CPP configuration and statistics of the master device.

**Examples**

```
Ruijie#show cpu-protect mboard
```

```
%cpu port bandwidth: 80000(pps)
```

**Description**

## 9.13 show cpu-protect summary

Use this command to display the CPP configuration and statistics of the master device.

**show cpu-protect summary**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** All configuration modes

**Usage Guide** N/A

**Configuration** 1. The following example checks all configuration and statistics of CPP.

#### Examples

```
Ruijie#show cpu-protect summary
%cpu port bandwidth: 100000(pps)
Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
-----
0               6000          0          0
1               6000          0          0
2               6000          0          0
3               6000          0          0
4               6000          0          0
5               6000          0          0
6               6000          0          0
```

| 7            | 6000          | 0              | 0         |           |       |       |

## 9.15 show cpu-protect type

Use this command to display the statistics of the specified type of packets

**show cpu-protect type** *packet-type* [ **device** *device\_num* ]

| Parameter<br>Description | Parameter          | Description                                                     |
|--------------------------|--------------------|-----------------------------------------------------------------|
|                          | <i>packet-type</i> | Packet type, which varies with products                         |
|                          | <i>all</i>         | Displays the configurations and statistics of all packet types. |
|                          | <i>device_num</i>  | As a single physical device, there is no device parameter.      |
|                          |                    |                                                                 |

**Defaults** N/A

**Command Mode** All configuration modes

**Usage Guide** N/A

**Configuration Examples** The following example displays the statistics of the ICMP packets.

```
Ruijie(config)#show cpu-protect type icmp
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
Total      Total Drop
-----
icmp                5             1500           50         0         10000
100
```

**Description**

## 9.16 show cpu-protect statistics

Use this command to display the statistics of all packets on the specified interface or the specified type of packets on an interface.

**show cpu-protect statistics** [ *interface interface-id* ]

**show cpu-protect statistics type** *packet-type*

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           |             |

|                     |                                         |
|---------------------|-----------------------------------------|
| <i>packet-type</i>  | Packet type, which varies with products |
| <i>Interface id</i> | Interface ID.                           |

**Defaults** N/A

**Command Mode** All configuration modes

**Usage Guide** N/A

**Configuration** 1. The following example displays the statistics of all packets on a specified interface.

**Examples** Ruijie#show cpu-protect statistics interface tenGigabitEthernet 0/33  
Te0/33

| Packet Type  | Rate (pps) | Drop (pps) | Total  | Total Drop |
|--------------|------------|------------|--------|------------|
| bpdu         | 0          | 0          | 0      | 0          |

## 10 DHCP Snooping Commands

### 10.1 clear ip dhcp snooping binding

Use this command to delete the dynamic user information from the DHCP Snooping binding database.

**clear ip dhcp snooping binding** [ *ip* ] [ *mac* ] [ **vlan** *vlan-id* ] [ **interface** *interface-id* ]

| Parameter Description | Parameter           | Description                                      |
|-----------------------|---------------------|--------------------------------------------------|
|                       | <i>mac</i>          | Specifies the user MAC address to be cleared.    |
|                       | <i>vlan-id</i>      | Specifies the ID of the VLAN to be cleared.      |
|                       | <i>ip</i>           | Specifies the IP address to be cleared.          |
|                       | <i>interface-id</i> | Specifies the ID of the interface to be cleared. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear the current dynamic user information from the DHCP Snooping binding database.

**Configuration Examples** The following example clears the dynamic database information from the DHCP Snooping binding database.

```
Ruijie# clear ip dhcp snooping binding
Ruijie# show ip dhcp snooping binding
Total number of bindings: 0
MacAddress IpAddress Lease(sec) Type VLAN Interface
-----
```

| Related Commands | Command                              | Description                                                     |
|------------------|--------------------------------------|-----------------------------------------------------------------|
|                  | <b>show ip dhcp snooping binding</b> | Displays the information of the DHCP Snooping binding database. |

**Platform Description** N/A

## 10.2 ip dhcp snooping

Use this command to enable the DHCP Snooping function globally.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping**

**no ip dhcp snooping**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** The **show ip dhcp snooping** command is used to display whether the DHCP Snooping function is enabled. Note that DHCP Snooping cannot coexist with private VLAN.

**Configuration** The following example enables the DHCP Snooping function.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping
Ruijie(config)# end
Ruijie# show ip dhcp snooping
Switch DHCP snooping status: ENABLE
DHCP snooping Verification of hwaddr field status: DISABLE
DHCP snooping database write-delay time: 0 seconds
DHCP snooping option 82 status: ENABLE
DHCP Snooping Support Bootp bind status: ENABLE
Interface          Trusted          Rate limit (pps)
-----
-----
```

| Related<br>Commands | Command                      | Description                                              |
|---------------------|------------------------------|----------------------------------------------------------|
|                     | <b>show ip dhcp snooping</b> | Displays the configuration information of DHCP Snooping. |
|                     | <b>ip dhcp snooping vlan</b> | Configures DHCP Snooping enabled VLAN.                   |

**Platform** N/A

**Description**

## 10.3 ip dhcp snooping bootp-bind

Use this command to enable DHCP Snooping BOOTP-bind function.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping bootp-bind**

**no ip dhcp snooping bootp-bind**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** By default, the DHCP Snooping only forwards BOOTP packets. With this function enabled, it can snoop BOOTP packets. After the BOOTP client requests an address successfully, the DHCP Snooping adds the BOOTP user to the static binding database.

**Configuration Examples** The following example enables the DHCP Snooping BOOTP-bind function.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping bootp-bind
Ruijie(config)# end
Ruijie# show ip dhcp snooping
Switch DHCP snooping status :ENABLE
Verification of hwaddr field status :DISABLE
DHCP snooping database write-delay time: 0 seconds
DHCP snooping option 82 status: ENABLE
DHCP snooping Support Bootp bind status: ENABLE
Interface           Trusted           Rate limit (pps)
-----
-----
```

| Related<br>Commands | Command                      | Description                               |
|---------------------|------------------------------|-------------------------------------------|
|                     | <b>show ip dhcp snooping</b> | Displays the DHCP Snooping configuration. |

**Platform Description** N/A

## 10.4 ip dhcp snooping check-giaddr

Use this command to enable DHCP Snooping to support the function of processing Relay requests.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping check-giaddr**

**no ip dhcp snooping check-giaddr**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

### Defaults

This function is disabled by default.

### Command Mode

Global configuration mode

### Usage Guide

After the feature is enabled, services using DHCP Snooping binding entries generated based on Relay requests, such as IP Source Guard/802.1x authentication, cannot be deployed. Otherwise, users fail to access the Internet.

After the feature is enabled, the **ip dhcp snooping verify mac-address** command cannot be used. Otherwise, DHCP Relay requests will be discarded and as a result, users fail to obtain addresses.

### Configuration Examples

The following example enables DHCP Snooping to support the function of processing Relay requests.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping check-giaddr
Ruijie(config)# end
```

**Related  
Commands**

| <b>show ip dhcp snooping</b> | Displays the configuration information of the DHCP Snooping. |

**Platform** N/A**Description**

## 10.5 ip dhcp snooping database write-delay

Use this command to configure the switch to write the dynamic user information of the DHCP Snooping binding database into the flash periodically.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping database write-delay** *time*

**no ip dhcp snooping database write-delay** *time*

**Parameter  
Description**

| Parameter   | Description                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------|
| <i>time</i> | The interval at which the system writes the dynamic user information of the DHCP Snooping database into the flash |

**Defaults** This function is disabled by default.**Command  
Mode** Global configuration mode**Usage Guide** This function avoids loss of user information after restart. In that case, users need to obtain IP addresses again for normal communication.**Configuration  
Examples** The following example sets the interval at which the switch writes the user information into the flash to 3600 seconds.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping database write-delay 3600
Ruijie(config)# end
Ruijie# show ip dhcp snooping
Switch DHCP snooping status: ENABLE
DHCP snooping Verification of hwaddr field status: ENABLE
```

```

DHCP snooping database write-delay time: 3600
DHCP snooping option 82 status: DISABLE
DHCP Snooping Support Bootp bind status: ENABLE
Interface          Trusted          Rate limit (pps)
-----

```

|------------------------------|--------------------------------------------------------------|
| <b>show ip dhcp snooping</b> | Displays the configuration information of the DHCP Snooping. |

**Platform** N/A**Description**

## 10.6 ip dhcp snooping database write-to-flash

Use this command to write the dynamic user information of the DHCP binding database into flash in real time.

**ip dhcp snooping database write-to-flash**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to write the dynamic user information of the DHCP binding database into flash in real time.

**Configuration** The following example writes the dynamic user information of the DHCP binding database into flash.

**Examples**

```

Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping database write-to-flash
Ruijie(config)# end
Ruijie#

```

**Platform** N/A**Description**

## 10.7 ip dhcp snooping information option

Use this command to add option82 to the DHCP request message. Use the **no** form of this command to restore the default setting.

**ip dhcp snooping information option** [ standard-format ]

**no ip dhcp snooping information option** [ standard-format ]

| Parameter<br>Description | Parameter       | Description                            |
|--------------------------|-----------------|----------------------------------------|
|                          | standard-format | The option82 uses the standard format. |

**Defaults** This function is disabled by default,

**Command Mode** Global configuration mode

**Usage Guide** This command adds option82 to the DHCP request message based on which the DHCP server assigns IP address.

**Configuration** The following example adds option82 to the DHCP request message.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping information option
Ruijie(config)# end
Ruijie# show ip dhcp snooping
Switch DHCP snooping status           :  ENABLE
DHCP snooping Verification of hwaddr status :  ENABLE
DHCP snooping database write-delay time   :    0
DHCP snooping option 82 status           :  DISABLE
DHCP Snooping Support Bootp bind status: ENABLE
Interface          Trusted          Rate limit (pps)
-----
-----
```

|                     | show ip dhcp snooping | Displays the DHCP Snooping configuration. |

**Platform** N/A

**Description**

## 10.8 ip dhcp snooping information option format remote-id

Use this command to set the option82 sub-option remote-id as the customized character string.  
Use the **no** form of this command to restore the default setting.

**ip dhcp snooping information option format remote-id { string *ascii-string* | hostname }**  
**no ip dhcp snooping information option format remote-id { string *ascii-string* | hostname }**

**Parameter  
Description**

| Parameter                         | Description                                                                            |
|-----------------------------------|----------------------------------------------------------------------------------------|
| <b>string</b> <i>ascii-string</i> | The content of the option82 remote-id extension format is customized character string. |
| <i>hostname</i>                   | The content of the option82 remote-id extension format hostname                        |

**Defaults** This function is disabled by default,

**Command  
Mode** Global configuration mode

**Usage Guide** This command sets the remote-id in the option82 to be added to the DHCP request message as the customized character string. The DHCP server will assign the IP address according to the option82 information.

**Configuration  
Examples** The following example adds the option82 into the DHCP request packets with the content of remote-id being hostname.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping information option format remote-id hostname
```

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform  
Description** N/A

## 10.9 ip dhcp snooping suppression

Use this command to set the port to be the suppression status.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping suppression**  
**no ip dhcp snooping suppression**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** This command denies all DHCP request messages under the port, that is, all the users under the port are prohibited to request addresses through DHCP.

**Configuration** The following example sets **fastEthernet 0/2** to be in the suppression status.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastEthernet 0/2
Ruijie(config-if)# ip dhcp snooping suppression
Ruijie(config-if)# end
```

**Related  
Commands**

| Command                      | Description                               |
|------------------------------|-------------------------------------------|
| <b>show ip dhcp snooping</b> | Displays the DHCP Snooping configuration. |

**Platform** N/A

**Description**

## 10.10 ip dhcp snooping trust

Use this command to set the trusted ports.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping trust**

**no ip dhcp snooping trust**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** All ports are untrusted by default.

**Command  
Mode** Interface configuration mode

**Usage Guide** Use this command to set a port as a trusted port. The DHCP response messages received under the trust port are forwarded normally, but the response messages received under the untrusted port will be discarded.

**Configuration** The following example sets **fastEthernet 0/1** as a trusted port:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ip dhcp snooping trust
Ruijie(config-if)# end
Ruijie# show ip dhcp snooping
```

```

Switch DHCP snooping status: ENABLE
DHCP snooping Verification of hwaddr field status: DISABLE
DHCP snooping database write-delay time: 0 seconds
DHCP snooping option 82 status: ENABLE
DHCP Snooping Support Bootp bind status:ENABLE
Interface          Trusted          Rate limit (pps)
-----
FastEthernet0/1 yes          unlimited

```

**Related  
Commands**

| Command                      | Description                               |
|------------------------------|-------------------------------------------|
| <b>show ip dhcp snooping</b> | Displays the DHCP Snooping configuration. |

**Platform** N/A

**Description**

## 10.11 ip dhcp snooping verify mac-address

Use this command to check whether the source MAC address of the DHCP request message matches against the **client addr** field of the DHCP message.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping verify mac-address**

**no ip dhcp snooping verify mac-address**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command  
Mode** Global configuration mode

**Usage Guide** Use this command to enable checking the validity of the source MAC address of the DHCP request message. Once the function is enabled, the system will discard the DHCP request message that fails to pass the source MAC address check.

**Configuration** The following example enables the check of the source MAC address of the DHCP request message.

**Examples**

```

Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping verify mac-address
Ruijie(config)# end
Ruijie# show ip dhcp snooping
Switch DHCP snooping status: ENABLE
Verification of hwaddr field status: ENABLE

```

```

DHCP snooping database write-delay time: 0 seconds
DHCP snooping option 82 status: ENABLE
DHCP Snooping Support Bootp bind status: ENABLE
Interface      Trusted      Rate limit (pps)

```

**Related  
Commands**

| Command                      | Description                               |
|------------------------------|-------------------------------------------|
| <b>show ip dhcp snooping</b> | Displays the DHCP Snooping configuration. |

**Platform** N/A

**Description**

## 10.12 ip dhcp snooping vlan

Use this command to enable DHCP Snooping for the specific VLAN.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping vlan** {vlan-rng | { vlan-min [ vlan-max ] } }

**no ip dhcp snooping vlan** {vlan-rng | { vlan-min [ vlan-max ] } }

**Parameter  
Description**

| Parameter       | Description                             |
|-----------------|-----------------------------------------|
| <i>vlan-rng</i> | VLAN range of effective DHCP Snooping   |
| <i>vlan-min</i> | Minimum VLAN of effective DHCP Snooping |
| <i>vlan-max</i> | Maximum VLAN of effective DHCP Snooping |

**Defaults** By default, once the DHCP Snooping is enabled globally, it takes effect for all VLANs.

**Command  
Mode** Global configuration mode

**Usage Guide** Use this command to configure effective DHCP Snooping VLAN by character string.

**Configuration** The following example enables the DHCP Snooping function in VLAN1000.

**Examples**

```

Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping vlan 1000
Ruijie(config)# end

```

**Related  
Commands**

| Command                 | Description                     |
|-------------------------|---------------------------------|
| <b>ip dhcp snooping</b> | Enables DHCP Snooping globally. |

**Platform** N/A

**Description**

## 10.13 ip dhcp snooping vlan information option change-vlan-to vlan

Use this command to enable the option82 sub-option circuit and change the VLAN in the circuit-id into the specified VLAN.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping vlan** *vlan-id* **information option change-vlan-to vlan** *vlan-id*

**no ip dhcp snooping vlan** *vlan-id* **information option change-vlan-to vlan** *vlan-id*

### Parameter Description

| Parameter      | Description                       |
|----------------|-----------------------------------|
| <i>vlan-id</i> | The ID of the VLAN to be replaced |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** With this command configured, the option82 is added to the DHCP request packets, the circuit-id in the option82 information is the specified VLAN and the DHCP server will assign the addresses according to the option82 information.

**Configuration Examples** The following adds the option82 to the DHCP request packets and changes the VLAN4094 in the option82 sub-option circuit-id to VLAN93:

```
Ruijie# configure terminal
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ip dhcp snooping vlan 4094 information option
change-vlan-to vlan 4093
Ruijie(config-if)# end
```

### Related Commands

| N/A     | N/A         |

**Platform Description** N/A

## 10.14 ip dhcp snooping vlan information option format-type circuit-id string

Use this command to configure the option82 sub-option circuit-id as user-defined (the storage format is ASCII) and to perform the packet forwarding. Use the **no** form of this command to restore the default setting.

**ip dhcp snooping vlan *vlan-id* information option format-type circuit-id string *ascii-string***  
**no ip dhcp snooping vlan *vlan-id* information option format-type circuit-id string *ascii-string***

**Parameter  
Description**

| Parameter           | Description                                        |
|---------------------|----------------------------------------------------|
| <i>vlan-id</i>      | The VLAN where the DHCP request packets are        |
| <i>ascii-string</i> | The user-defined content to fill to the Circuit ID |

**Defaults** This function is disabled by default.

**Command  
Mode** Interface configuration mode

**Usage Guide** This command is used to add the option82 to the DHCP request packets. The content of the sub-option circuit-id is customized, and the DHCP server will assign the addresses according the option82 information.

**Configuration  
Examples** The following example adds the option82 to the DHCP request packets with the content of the sub-option circuit-id being *port-name*.

```
Ruijie# configure terminal
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ip dhcp snooping vlan 4094 information option format-type
circuit-id string port-name
Ruijie(config-if)# end
```

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform  
Description** This command is supported on all switches.

## 10.15 ip dhcp snooping vlan max-user

Use this command to set the maximum number of users bound with the VLAN. Use the **no** form of this command to restore the default setting.

**ip dhcp snooping vlan *vlan-word* max-user *user-number***  
**no ip dhcp snooping vlan *vlan-word* max-user *user-number***

**Parameter  
Description**

| Parameter          | Description                                      |
|--------------------|--------------------------------------------------|
| <i>vlan-word</i>   | The VLAN range.                                  |
| <i>user-number</i> | The maximum number of users bound with the VLAN. |

**Defaults** The limit for the number of users bound with the VLAN is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to set the maximum number of users bound with the VLAN. This function combined with the corresponding topology can prevent illegal DHCP packet attacks.

**Configuration Examples** The following example sets the maximum number of users bound with VLAN 1-10 and VLAN 20 to 30 respectively.

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip dhcp snooping vlan 1-10,20 max-user 30
Ruijie(config-if-GigabitEthernet 0/1)# end
```

## 10.16 renew ip dhcp snooping database

Use this command to import the information in current flash to the DHCP Snooping binding database manually as needed.

**renew ip dhcp snooping database**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to import the backup file information to the DHCP Snooping database in real time.

**Configuration Examples** The following example imports the backup file information to the DHCP Snooping database.

```
Ruijie# renew ip dhcp snooping database
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** This command is supported on all switches.

**Description**

## 10.17 show ip dhcp snooping

Use this command to display the DHCP Snooping configuration.

**show ip dhcp snooping**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the DHCP Snooping configuration.

**Examples**

```
Ruijie# show ip dhcp snooping
Switch DHCP snooping status :ENABLE
Verification of hwaddr field status :DISABLE
DHCP snooping database write-delay time: 0 seconds
DHCP snooping option 82 status: ENABLE
DHCP snooping Support Bootp bind status: ENABLE
Interface           Trusted      Rate limit (pps)
-----
-----
```

| Related Commands | Command                                    | Description                                                                    |
|------------------|--------------------------------------------|--------------------------------------------------------------------------------|
|                  | <b>ip dhcp snooping</b>                    | Enables the DHCP Snooping globally.                                            |
|                  | <b>ip dhcp snooping verify mac-address</b> | Enables the check of source MAC address of DHCP Snooping packets.              |
|                  | <b>ip dhcp snooping write-delay</b>        | Sets the interval of writing user information to the backup file periodically. |
|                  | <b>ip dhcp snooping information option</b> | Adds option82 to the DHCP request message.                                     |
|                  | <b>ip dhcp snooping bootp-bind</b>         | Enables the DHCP Snooping bootp bind function.                                 |

|                               |                                |
|-------------------------------|--------------------------------|
| <b>ip dhcp snooping trust</b> | Sets the port as a trust port. |

**Description**

## 10.18 show ip dhcp snooping binding

Use this command to display the information of the DHCP Snooping binding database.

**show ip dhcp snooping binding**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the information of the DHCP Snooping binding database.

**Examples**

```
Ruijie# show ip dhcp snooping binding
Total number of bindings: 1
NO.    MACADDRESS      IPADDRESS      LEASE (SEC)    TYPE           VLAN
INTERFACE
-----
1      0000.0000.0001      1.1.1.1        78128          DHCP-Snooping 1
GigabitEthernet 0/1
```

| Related Commands | Command                               | Description                                                                  |
|------------------|---------------------------------------|------------------------------------------------------------------------------|
|                  | <b>ip dhcp snooping binding</b>       | Adds the static user information to the DHCP Snooping database.              |
|                  | <b>clear ip dhcp snooping binding</b> | Clears the dynamic user information from the DHCP Snooping binding database. |

**Platform** N/A

**Description**

## 11 NFPP Commands

### 11.1 arp-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs. Use the **no** or **default** form of this command to restore the default setting.

**arp-guard attack-threshold** { **per-src-ip** | **per-src-mac** | **per-port** } *pps*

**no arp-guard attack-threshold** { **per-src-ip** | **per-src-mac** | **per-port** }

**default arp-guard attack-threshold** { **per-src-ip** | **per-src-mac** | **per-port** }

#### Parameter Description

| Parameter          | Description                                                             |
|--------------------|-------------------------------------------------------------------------|
| <b>per-src-ip</b>  | Sets the attack threshold for each source IP address.                   |
| <b>per-src-mac</b> | Sets the attack threshold for each source MAC address.                  |
| <b>per-port</b>    | Sets the attack threshold for each port.                                |
| <i>pps</i>         | Sets the attack threshold, in the range from 1 to 19999 in unit of pps. |

#### Defaults

By default, the attack threshold for each source IP address and source MAC address is 3000pps; and the attack threshold for each port is 8000pps.

#### Command Mode

NFPP configuration mode.

#### Usage Guide

The attack threshold shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the global attack threshold.

#### Examples

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard attack-threshold per-src-ip 2
Ruijie(config-nfpp)# arp-guard attack-threshold per-src-mac 3
Ruijie(config-nfpp)# arp-guard attack-threshold per-port 50
```

#### Related Commands

| Command                            | Description                                             |
|------------------------------------|---------------------------------------------------------|
| <b>nfpp arp-guard policy</b>       | Displays the rate-limit threshold and attack threshold. |
| <b>show nfpp arp-guard summary</b> | Displays the configuration.                             |
| <b>show nfpp arp-guard hosts</b>   | Displays the monitored host.                            |
| <b>clear nfpp arp-guard hosts</b>  | Clears the isolated host.                               |

#### Platform Description

N/A

## 11.2 arp-guard enable

Use this command to enable the anti-ARP guard function globally. Use the **no** or **default** form of this command to restore the default setting.

**arp-guard enable**

**no arp-guard enable**

**default arp-guard enable**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

### Defaults

This function is enabled by default.

### Command Mode

NFPP configuration mode.

### Usage Guide

N/A

### Configuration

The following example enables the anti-ARP guard function globally.

### Examples

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard enable
```

### Related Commands

| Command                            | Description                                   |
|------------------------------------|-----------------------------------------------|
| <b>nfpp arp-guard enable</b>       | Enables the anti-ARP attack on the interface. |
| <b>show nfpp arp-guard summary</b> | Displays the configuration.                   |

### Platform

### Description

## 11.3 arp-guard isolate-period

Use this command to set the arp-guard isolate time globally. Use the **no** or **default** form of this command to restore the default setting.

**arp-guard isolate-period { *seconds* | **permanent** }**

**no arp-guard isolate-period**

**default arp-guard isolate-period**

### Parameter Description

| Parameter      | Description                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the isolate time. The value is 0, or in the range from 30 to 86400 in the unit of seconds. |

|                  |                      |
|------------------|----------------------|
| <b>permanent</b> | Permanent isolation. |
|------------------|----------------------|

**Defaults** The default isolate time is 0, which means no isolation.

**Command Mode** NFPP configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the arp-guard isolate time globally to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard isolate-period 180
```

| Related Commands | Command                              | Description                             |
|------------------|--------------------------------------|-----------------------------------------|
|                  | <b>nfpp arp-guard isolate-period</b> | Sets the isolate time on the interface. |
|                  | <b>show nfpp arp-guard summary</b>   | Displays the configuration.             |
|                  |                                      |                                         |

**Platform** N/A

**Description**

## 11.4 arp-guard isolate-forwarding enable

Use this command to enable packet forwarding through NFPP isolation. Use the **no** form of this command to disable this function. Use the **default** form of this command to restore the default setting.

**arp-guard isolate-forwarding enable**

**no arp-guard isolate-forwarding enable**

**default arp-guard isolate-forwarding enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration** The following example enables packet forwarding through NFPP isolation.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard isolate-forwarding enable
```

| Related Commands | Command | Description |

Platform N/A  
Description

## 11.5 arp-guard monitored-host-limit

Use this command to set the maximum monitored host number. Use the **no** or **default** form of this command to restore the default setting.

**arp-guard monitored-host-limit** *number*

**no arp-guard monitored-host-limit**

**default arp-guard monitored-host-limit**

| Parameter Description | Parameter     | Description                                                           |
|-----------------------|---------------|-----------------------------------------------------------------------|
|                       | <i>number</i> | The maximum monitored host number, in the range from 1 to 4294967295. |

Defaults The default is 20000.

Command NFPP configuration mode  
Mode

**Usage Guide** If the monitored host number has reached the default 20000, the administrator shall set the max-number smaller than 20000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts. to remind the administrator of the invalid configuration and removing the monitored hosts.  
When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_ARP\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20000 monitored hosts.to remind the administrator.

**Configuration** The following example sets the maximum monitored host number to 200.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard monitored-host-limit 200
```

| Related Commands | Command                            | Description                 |

Platform N/A  
Description

## 11.6 arp-guard monitor-period

Use this command to configure the arp guard monitor time. Use the **no** or **default** form of this command to restore the default setting.

**arp guard monitor-period** *seconds*

**no arp-guard monitor-period**

**default arp-guard monitor-period**

| Parameter<br>Description | Parameter      | Description                                                                   |
|--------------------------|----------------|-------------------------------------------------------------------------------|
|                          | <i>seconds</i> | Sets the monitor time, in the range from 180 to 86400 in the unit of seconds. |

**Defaults** The default is 600.

**Command Mode** NFPP configuration mode.

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration Examples** The following example sets the arp guard monitor time to 180 seconds.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard monitor-period 180
```

**Description**

## 11.7 arp-guard rate-limit

Use this command to set the arp guard rate limit. Use the **no** or **default** form of this command to restore the default setting.

**arp-guard rate-limit** { **per-src-ip** | **per-src-mac** | **per-port** } *pps*

**no arp-guard rate-limit { per-src-ip | per-src-mac | per-port }**  
**default arp-guard rate-limit { per-src-ip | per-src-mac | per-port }**

**Parameter  
Description**

| Parameter          | Description                                      |
|--------------------|--------------------------------------------------|
| <b>per-src-ip</b>  | Setsthe rate limit for each source IP address.   |
| <b>per-src-mac</b> | Sets the rate limit for each source MAC address. |
| <b>per-port</b>    | Sets the rate limit for each port.               |
| <i>pps</i>         | Sets the rate limit, in the range of 1 to 19999  |

**Defaults** The default rate limit for each source IP address and MAC address is 30pps; the default rate limit for each port is 5000pps.

**Command  
Mode** NFPP configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the arp guard rate limit.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard rate-limit per-src-ip 2
Ruijie(config-nfpp)# arp-guard rate-limit per-src-mac 3
Ruijie(config-nfpp)# arp-guard rate-limit per-port 50
```

## 11.8 arp-guard ratelimit-forwarding enable

Use this command to set the port based arp guard rate limit. Use the **no** form of this command to disable this function. Use the **default** form of this command to restore the default setting.

**arp-guard ratelimit-forwarding enable**  
**no arp-guard ratelimit-forwarding enable**  
**default arp-guard ratelimit-forwarding enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the port based arp guard rate limit..

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard ratelimit-forwarding enable
```

**Description**

## 11.9 arp-guard scan-threshold

Use this command to set the global scan threshold. Use the **no** or **default** form of this command to restore the default setting.

**arp-guard scan-threshold** *pkt-cnt*

**no arp-guard scan-threshold**

**default arp-guard scan-threshold**

| Parameter Description | Parameter      | Description                                            |
|-----------------------|----------------|--------------------------------------------------------|
|                       | <i>pkt-cnt</i> | Sets the scan threshold, in the range from 1 to 19999. |

**Defaults** The default scan threshold is 100.

**Command Mode** NFPP configuration mode

**Usage Guide** The scanning may occur on the condition that:

- more than 15 packets are received within 10 seconds;
- the source MAC address for the link layer is constant while the source IP address is uncertain;
- the source MAC and IP address for the link layer is constant while the destination IP address is uncertain.

**Configuration** The following example sets the global scan threshold to 20pps.

**Examples**

```
Ruijie(config)# nfpp
```

```
Ruijie(config-nfpp)# arp-guard scan-threshold 20
```

## 11.10 clear nfpp arp-guard hosts

Use this command to clear the monitored host isolation.

**clear nfpp arp-guard hosts** [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* | *mac-address* ]

#### Parameter Description

| Parameter           | Description                         |
|---------------------|-------------------------------------|
| <i>vid</i>          | Sets the VLAN ID.                   |
| <i>interface-id</i> | Sets the interface name and number. |
| <i>ip-address</i>   | Sets the IP address.                |
| <i>mac-address</i>  | Sets the MAC address.               |

**Defaults** N/A.

**Command Mode** Privileged EXEC mode.

**Usage Guide** Use this command without the parameter to clear all monitored hosts.

**Configuration Examples** The following example clears the monitored host isolation.

```
Ruijie# clear nfpp arp-guard hosts vlan 1 interface g0/1
```

|                     | show nfpp arp-guard scan   | Displays the ARP scanning table.  |

**Platform** N/A

**Description**

## 11.12 clear nfpp define *name* hosts

Use this command to clear the monitored hosts. If the host is isolated, you need to disisolate it.

**clear nfpp define *name* hosts** [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* ] [ *mac-address* ]  
[ *ipv6-address* ]

| Parameter<br>Description | Parameter           | Description        |
|--------------------------|---------------------|--------------------|
|                          | <i>name</i>         | Defines guard name |
|                          | <i>vid</i>          | VLAN ID            |
|                          | <i>interface-id</i> | Interface name     |
|                          | <i>ip-address</i>   | IP address         |
|                          | <i>ipv6-address</i> | IPv6 address       |

**Defaults** N/A

**Command** Privileged EXEC mode.  
**Mode**

**Usage Guide** Use this command without the parameter to clear all monitored hosts in the self-defined range.

**Configuration** The following example clears the monitored hosts.

**Examples** Ruijie# clear nfpp define tcp hosts vlan 1 interface g 0/1

| Related<br>Commands | Command                | Description                  |

|                  | icmp-guard attack-threshold | Sets the global attack threshold.              |
|                  | nfpp icmp-guard policy      | Sets the limit threshold and attack threshold. |
|                  | show nfpp icmp-guard hosts  | Displays the monitored host.                   |

**Platform** N/A

**Description**

## 11.16 clear nfpp ip-guard hosts

Use this command to clear the monitored host isolation.

**clear nfpp ip-guard hosts** [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* ]

| Parameter Description | Parameter           | Description                         |
|-----------------------|---------------------|-------------------------------------|
|                       | <i>vid</i>          | Sets the VLAN ID.                   |
|                       | <i>interface-id</i> | Sets the interface name and number. |
|                       | <i>ip-address</i>   | Sets the IP address.                |

**Defaults** N/A.

**Command Mode** Privileged EXEC mode.

**Usage Guide** Use this command without the parameter to clear all monitored hosts.

**Configuration** The following example clears the monitored host isolation.

**Examples** Ruijie# clear nfpp ip-guard hosts vlan 1 interface g0/1

| Related Commands | Command | Description |

|----------------------------------|------------------------------------------------|
| <b>ip-guard attack-threshold</b> | Sets the global attack threshold.              |
| <b>nfpp ip-guard policy</b>      | Sets the limit threshold and attack threshold. |
| <b>show nfpp ip-guard hosts</b>  | Displays the monitored host.                   |

**Platform** N/A

**Description**

## 11.17 clear nfpp nd-guard hosts

Use this command to remove the speed limit on the host.

**clear nfpp nd-guard hosts** [ **vlan** *vid* ] [**interface** *interface-id*]

| Parameter<br>Description | Parameter           | Description                         |
|--------------------------|---------------------|-------------------------------------|
|                          | <i>vid</i>          | Sets the VLAN ID.                   |
|                          | <i>interface-id</i> | Sets the interface name and number. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** This command without any parameter is used to remove speed limit on all monitored hosts.

**Configuration Examples** The following example removes speed limit on interface g0/1 in VLAN 1..

```
Ruijie# clear nfpp nd-guard hosts vlan 1 interface g0/1
```

**Prompt** N/A

**Messages**

**Platform** N/A

**Description**

## 11.18 clear nfpp log

Use this command to clear the NFPP log buffer area.

**clear nfpp log**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration** The following example clears the NFPP log buffer area.

**Examples** Ruijie# clear nfpp log

**Related Commands**

| Command              | Description                                                 |
|----------------------|-------------------------------------------------------------|
| <b>show nfpp log</b> | Displays the NFPP log configuration or the log buffer area. |

**Platform** N/A

**Description**

## 11.19 cpu-protect sub-interface { manage | protocol | route } percent

Use this command to configure the percent value of each type of packets occupied in the buffer area.

Use the **no** or **default** form of this command to restore the default setting.

**cpu-protect sub-interface { manage | protocol | route } percent** *percent\_value*

**no cpu-protect sub-interface {manage|protocol|route} percent**

**default cpu-protect sub-interface {manage|protocol|route} percent**

**Parameter Description**

| Parameter            | Description                                    |
|----------------------|------------------------------------------------|
| <i>percent_value</i> | The percent value, in the range from 1 to 100. |

**Defaults** The default percent values of each type of packets occupied in the buffer area are:

Manage packets: 30;

Route packets: 20;

Protocol packets: 45.

**Command Mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the percent value of management packets in the buffer area to 60.

**Examples** Ruijie(config)# cpu-protect sub-interface manage  
percent 60

| Related Commands | Command                                                            | Description                                               |
|------------------|--------------------------------------------------------------------|-----------------------------------------------------------|
|                  | <b>cpu-protect sub-interface { manage   protocol   route } pps</b> | Configures the traffic bandwidth of each type of packets. |

**Platform** N/A

**Description**

## 11.20 cpu-protect sub-interface { manage | protocol | route } pps

Use this command to configure the traffic bandwidth of each type of packets. Use the **no** or **default** form of this command to restore the default setting.

**cpu-protect sub-interface { manage | protocol | route } pps pps\_value**

**no cpu-protect sub-interface { manage | protocol | route } pps**

**default cpu-protect sub-interface { manage | protocol | route } pps**

| Parameter Description | Parameter        | Description                                           |
|-----------------------|------------------|-------------------------------------------------------|
|                       | <i>pps_value</i> | The rate limit threshold, in the range from 1 to 8192 |

**Defaults** The default traffic bandwidths of each type of packets are:  
 Manage packets: 3000pps;  
 Route packets: 3000pps;  
 Protocol packets: 3000pps.

**Command Mode** Global configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example sets the traffic bandwidth of management packets to 2000 pps.

**Examples** Ruijie(config)# cpu-protect sub-interface manage pps 2000

| Related Commands | Command                                                                | Description                                                                       |
|------------------|------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
|                  | <b>cpu-protect sub-interface { manage   protocol   route } percent</b> | Configures the percent value of each type of packets occupied in the buffer area. |

**Description**

## 11.21 define

Use this command to define the anti-attack type.

Use the **no** or **default** form of this command to restore the default setting.

**define** *name*

**no define** *name*

**default define** *name*

| Parameter<br>Description | Parameter   | Description                                |
|--------------------------|-------------|--------------------------------------------|
|                          | <i>name</i> | Name of the user-defined anti-attack type. |

**Defaults** N/A

**Command Mode** NFPP configuration mode

**Usage Guide** Use this command to define the anti-attack type.

**Configuration** The following example creates the user-defined anti-attack type.

**Examples**

```
Ruijie(config)# nfppRuijie(config-nfpp)# define tcp
Ruijie(config-nfpp-define)#
```

| Related<br>Commands | Command                         | Description                                     |
|---------------------|---------------------------------|-------------------------------------------------|
|                     | <b>show nfpp define summary</b> | Displays the defined anti-attack configuration. |

**Platform** N/A

**Description**

## 11.22 define enable

Use this command to enable the user-defined anti-attack globally. Use the **no** or **default** form of this command to restore the default setting.

**define** *name* **enable**

**no define** *name* **enable**

**default define** *name* **enable**

| Parameter<br>Description | Parameter   | Description        |
|--------------------------|-------------|--------------------|
|                          | <i>name</i> | Defines guard name |

**Defaults** This function is disabled by default.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** This command takes effect only after the match, rate-limit and attack-threshold have been configured.

**Configuration** The following example enabled the user-defined anti-attack globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)#define tcp enable
```

**Related  
Commands**

| Command                         | Description                                         |

| <b>show nfpp define summary</b> | Displays the user-defined anti-attack configuration |

**Platform** N/A

**Description**

## 11.23 dhcp-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs. Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard attack-threshold { per-src-mac | per-port } pps**

**no dhcp-guard attack-threshold { per-src-mac | per-port }**

**default dhcp-guard attack-threshold { per-src-mac | per-port }**

**Parameter  
Description**

| Parameter          | Description                                                       |
|--------------------|-------------------------------------------------------------------|
| <b>per-src-mac</b> | Sets the attack threshold for each source MAC address.            |
| <b>per-port</b>    | Sets the attack threshold for each port.                          |
| <i>pps</i>         | Sets the attack threshold, in pps. The valid range is 1 to 19999. |

**Defaults**

The default settings are as follows:

For the 11.X CM supervisor module, the attack thresholds for each source MAC address and each port are 10 pps and 1500 pps respectively.

For the 11.X CMII supervisor module, the attack thresholds for each source MAC address and each port are 10 pps and 10000 pps respectively.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the global attack threshold.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard attack-threshold per-src-mac 15
Ruijie(config-nfpp)# dhcp-guard attack-threshold per-port 200
```

|                     | <b>show nfpp dhcp-guard summary</b> | Displays the configuration.                             |
|                     | <b>show nfpp dhcp-guard hosts</b>   | Displays the monitored host list.                       |
|                     | <b>clear nfpp dhcp-guard hosts</b>  | Clears the monitored host.                              |

**Platform** N/A

**Description**

## 11.24 dhcp-guard enable

Use this command to enable the DHCP anti-attack function. Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard enable**

**no dhcp-guard enable**

**default dhcp-guard enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** NFPP configuration mode.

**Usage Guide** N/A

**Configuration** The following example enables the DHCP anti-attack function.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard enable
```

| Related<br>Commands | Command | Description |

**Description**

## 11.25 dhcp-guard isolate-period

Use this command to set the isolate time globally. Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard isolate-period { seconds | permanent }**

**no dhcp-guard isolate-period**

**default dhcp-guard isolate-period**

**Parameter  
Description**

| Parameter        | Description                                                                                    |
|------------------|------------------------------------------------------------------------------------------------|
| <i>seconds</i>   | Sets the isolate time. The value is 0 or in the range from 30 to 86400 in the unit of seconds. |
| <b>permanent</b> | Permanent isolation.                                                                           |

**Defaults** The default isolate time is 0, which means no isolation.

**Command  
Mode** NFPP configuration mode

**Usage Guide** The isolate period can be configured globally or based on the interface. For one interface, if the isolate period is not set based on the interface, the global value shall be adopted; or the interface-based isolate period shall be adopted.

**Configuration** The following example sets the isolate time globally to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard isolate-period 180
```

**Related  
Commands**

| Command                               | Description                             |
|---------------------------------------|-----------------------------------------|
| <b>nfpp dhcp-guard isolate-period</b> | Sets the isolate time on the interface. |
| <b>show nfpp dhcp-guard summary</b>   | Displays the configuration.             |

**Platform** N/A

**Description**

## 11.26 dhcp-guard monitored-host-limit

Use this command to set the maximum monitored host number. Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard monitored-host-limit *number***

**no dhcp-guard monitored-host-limit**  
**default dhcp-guard monitored-host-limit**

**Parameter  
Description**

| Parameter     | Description                                                           |
|---------------|-----------------------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to 4294967295. |

**Defaults**

The default is 20000.

**Command  
Mode**

NFPP configuration mode

**Usage Guide**

If the monitored host number has reached the default 20000, the administrator shall set the max-number smaller than 20000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts. to remind the administrator of the invalid configuration and removing the monitored hosts.

When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_ARP\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20000 monitored hosts.to remind the administrator.

**Configuration**

The following example sets the maxmum monitored host number to 200.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard monitored-host-limit 200
```

**Related  
Commands**

| Command                             | Description                 |
|-------------------------------------|-----------------------------|
| <b>show nfpp dhcp-guard summary</b> | Displays the configuration. |

**Platform**

N/A

**Description**

## 11.27 dhcp-guard monitor-period

Use this command to configure the monitor time. Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard monitor-period** *seconds*  
**no dhcp-guard monitor-period**  
**default dhcp-guard monitor-period**

**Parameter  
Description**

| Parameter      | Description                                                                   |
|----------------|-------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the monitor time, in the range from 180 to 86400 in the unit of seconds. |

**Defaults** The default is 600.

**Command Mode** NFPP configuration mode.

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration Examples** The following example sets the monitor time to 180 seconds.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard monitor-period 180
```

**Related Commands**

| Command                             | Description                       |

| <b>clear nfpp dhcp-guard hosts</b>  | Clears the isolated host.         |

**Platform** N/A

**Description**

## 11.28 dhcp-guard rate-limit

Use this command to set the rate-limit threshold globally. Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard rate-limit { per-src-mac | per-port } pps**

**no dhcp-guard rate-limit { per-src-mac | per-port }**

**default dhcp-guard rate-limit { per-src-mac | per-port }**

**Parameter Description**

| Parameter          | Description                                      |
|--------------------|--------------------------------------------------|
| <b>per-src-mac</b> | Sets the rate limit for each source MAC address. |
| <b>per-port</b>    | Sets the rate limit for each port.               |
| <i>pps</i>         | Sets the rate limit, in the range of 1 to 19999  |

**Defaults** The default settings are as follows:

For the 11.X CM supervisor module, the rate-limit thresholds for each source MAC address and each port are 5 pps and 1200 pps respectively.

For the 11.X CMII supervisor module, the rate-limit thresholds for each source MAC address and

each port are 5 pps and 8000 pps respectively.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the rate-limit threshold globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard rate-limit per-src-mac 8
Ruijie(config-nfpp)# dhcp-guard rate-limit per-port 100
```

**Description**

## 11.29 dhcpv6-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs. Use the **no** or **default** form of this command to restore the default setting.

**dhcpv6-guard attack-threshold { per-src-mac | per-port } pps**

**no dhcpv6-guard attack-threshold {per-src-mac | per-port}**

**default dhcpv6-guard attack-threshold { per-src-mac | per-port}**

**Parameter  
Description**

| Parameter          | Description                                                     |
|--------------------|-----------------------------------------------------------------|
| <b>per-src-mac</b> | Sets the attack threshold for each source MAC address.          |
| <b>per-port</b>    | Sets the attack threshold for each port.                        |
| <i>pps</i>         | Sets the attack threshold, in the range is from 1 to 19999 pps. |

**Defaults**

The default settings are as follows:

For the 11.X CM supervisor module, the attack thresholds for each source MAC address and each port are 10 pps and 1500 pps respectively.

For the 11.X CMII supervisor module, the attack thresholds for each source MAC address and each port are 10 pps and 10000 pps respectively.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** N/A.

**Configuration** The following example sets the global attack threshold.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcpv6-guard attack-threshold per-src-mac 15
Ruijie(config-nfpp)# dhcpv6-guard attack-threshold per-port 200
```

## 11.32 dhcpv6-guard monitor-period

Use this command to configure the monitor time. Use the **no** or **default** form of this command to restore the default setting.

**dhcpv6-guard monitor-period** *seconds*

**no dhcpv6-guard monitor-period**

**default dhcpv6-guard monitor-period**

### Parameter Description

| Parameter      | Description                                                                   |
|----------------|-------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the monitor time, in the range from 180 to 86400 in the unit of seconds. |

### Defaults

The default is 600.

### Command Mode

NFPP configuration mode.

### Usage Guide

When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

### Configuration

The following example sets the monitor time to 180 seconds.

### Examples

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcpv6-guard monitor-period 180
```

### Description

## 11.33 dhcpv6-guard rate-limit

Use this command to set the rate-limit threshold globally. Use the **no** or **default** form of this command to restore the default setting.

**dhcpv6-guard rate-limit** { **per-src-mac** | **per-port** } *pps*

**no dhcpv6-guard rate-limit { per-src-mac | per-port }**  
**default dhcpv6-guard rate-limit { per-src-mac | per-port }**

**Parameter  
Description**

| Parameter          | Description                                        |
|--------------------|----------------------------------------------------|
| <b>per-src-mac</b> | Sets the rate limit for each source MAC address.   |
| <b>per-port</b>    | Sets the rate limit for each port.                 |
| <i>pps</i>         | Sets the rate limit, in the range from 1 to 19999. |

**Defaults**

The default settings are as follows:

For the 11.X CM supervisor module, the rate-limit thresholds for each source MAC address and each port are 5 pps and 1200 pps respectively.

For the 11.X CMII supervisor module, the rate-limit thresholds for each source MAC address and each port are 5 pps and 8000 pps respectively.

**Command  
Mode**

NFPP configuration mode

**Usage Guide**

N/A

**Configuration  
Examples**

The following example sets the rate-limit threshold globally.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcpv6-guard rate-limit per-src-mac 8
Ruijie(config-nfpp)# dhcpv6-guard rate-limit per-port 100
```

**Description**

## 11.34 global-policy

Use this command to set the rate-limit threshold and attack threshold based on the host or port. Use the **no** or **default** form of this command to restore the default setting.

**global-policy { per-src-mac | per-src-ip | per-port } rate-limit-pps attack-threshold-pps**  
**no global-policy { per-src-mac | per-src-ip | per-port }**  
**default global-policy { per-src-mac | per-src-ip | per-port }**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                             |                                                                                    |
|-----------------------------|------------------------------------------------------------------------------------|
| <b>per-src-ip</b>           | Performs the rate statistics based on the source IP / VID and port.                |
| <b>per-src-mac</b>          | Performs the rate statistics based on the source MAC / VID and port.               |
| <b>per-port</b>             | Performs the rate statistics based on each physical port of receiving the packets. |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold.                                                     |
| <i>attack-threshold-pps</i> | Sets the attack threshold.                                                         |

**Defaults** N/A

**Command** NFPP define configuration mode.  
**Mode**

**Usage Guide** To create a user-defined anti-attack type, the classification rule for the rate statistics must be specified, that is, recognize the host based on the source IP address/ source MAC address for the user-defined packets rate statistics based on the user / port and specify the rate-limit threshold and attack threshold for each classification. The rate-limit threshold shall be equal to or greater than the attack threshold. If the rate is greater than the rate-limit threshold, the packets that meet this classification rule will be discarded. If the rate exceeds the attack threshold, the user will be regarded as an attacker. The log will be printed and the trap will be sent.

**Configuration** The following example sets the rate-limit threshold and attack threshold based on the host or port.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nfpp define tcp
Ruijie(config-nfpp-define)# global-policy per-src-ip 10 20
Ruijie(config-nfpp-define)# global-policy per-port 100 200
```

|---------------------------------------|-----------------------------------------------------|
| <b>nfpp define <i>name</i> policy</b> | Sets the rate-limit threshold and attack threshold. |
| <b>show nfpp define summary</b>       | Displays the user-defined anti-attack configuration |

**Platform** N/A

**Description**

## 11.35 icmp-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs. Use the **no** or **default** form of this command to restore the default setting.

```
icmp-guard attack-threshold { per-src-ip | per-port } pps
no icmp-guard attack-threshold { per-src-ip | per-port }
default icmp-guard attack-threshold { per-src-ip | per-port }
```

| Parameter<br>Description | Parameter         | Description                                                                 |
|--------------------------|-------------------|-----------------------------------------------------------------------------|
|                          | <b>per-src-ip</b> | Sets the attack threshold for each source IP address.                       |
|                          | <b>per-port</b>   | Sets the attack threshold for each port.                                    |
|                          | <i>pps</i>        | Sets the attack threshold, in the range from 1 to 19999 in the unit of pps. |

**Defaults** The default settings are as follows:

For the 11.X CM supervisor module, the attack thresholds for each source IP address and each port are 2000 pps and 4000 pps respectively.

For the 11.X CMII supervisor module, the attack thresholds for each IP MAC address and each port are 2500 pps and 4500 pps respectively.

**Command Mode** NFPP configuration mode.

**Usage Guide** N/A.

**Configuration Examples** The following example sets the global attack threshold.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard attack-threshold per-src-ip 600
Ruijie(config-nfpp)# icmp-guard attack-threshold per-port 1200
```

|                     | <b>show nfpp icmp-guard hosts</b>   | Displays the monitored host list.                       |
|                     | <b>clear nfpp icmp-guard hosts</b>  | Clears the monitored host.                              |

**Platform** N/A

**Description**

## 11.36 icmp-guard enable

Use this command to enable the ICMP anti-attack function. Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard enable**

**no icmp-guard enable**

**default icmp-guard enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** NFPP configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example enables the ICMP anti-attack function globally.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard enable
```

| Related<br>Commands | Command                             | Description                                             |
|---------------------|-------------------------------------|---------------------------------------------------------|
|                     | <b>nfpp icmp-guard enable</b>       | Enables the ICMP anti-attack function on the interface. |
|                     | <b>show nfpp icmp-guard summary</b> | Displays the configuration.                             |

**Platform Description** N/A

## 11.37 icmp-guard isolate-period

Use this command to set the isolate time globally. Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard isolate-period** { *seconds* | **permanent** }

**no icmp-guard isolate-period**

**default icmp-guard isolate-period**

| Parameter<br>Description | Parameter        | Description                                                                                       |
|--------------------------|------------------|---------------------------------------------------------------------------------------------------|
|                          | <i>seconds</i>   | Sets the isolate time. The value is in the range is 0 or from 30 to 86400 in the unit of seconds. |
|                          | <b>permanent</b> | Permanent isolation.                                                                              |

**Defaults** The default isolate time is 0, which means no isolation.

**Command Mode** NFPP configuration mode

**Usage Guide** The isolate period can be configured globally or based on the interface. For one interface, if the

isolate period is not set based on the interface, the global value shall be adopted; or the interface-based isolate period shall be adopted.

**Configuration** The following example sets the isolate time globally to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard isolate-period 180
```

**Related  
Commands**

| Command                               | Description                             |
|---------------------------------------|-----------------------------------------|
| <b>nfpp icmp-guard isolate-period</b> | Sets the isolate time on the interface. |
| <b>show nfpp icmp-guard summary</b>   | Displays the configuration.             |

**Platform** N/A

**Description**

## 11.38 icmp-guard monitored-host-limit

Use this command to set the maximum monitored host number. Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard monitored-host-limit** *number*

**no icmp-guard monitored-host-limit**

**default icmp-guard monitored-host-limit**

**Parameter  
Description**

| Parameter     | Description                                                           |
|---------------|-----------------------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to 4294967295. |

**Defaults** The default is 20000.

**Command  
Mode** NFPP configuration mode

**Usage Guide** If the monitored host number has reached the default 20000, the administrator shall set the max-number smaller than 20000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts. to remind the administrator of the invalid configuration and removing the monitored hosts. When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_ARP\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20000 monitored hosts to remind the administrator.

**Configuration** The following example sets the maximum monitored host number to 200.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard monitored-host-limit 200
```

| Related<br>Commands | Command                             | Description                 |
|---------------------|-------------------------------------|-----------------------------|
|                     | <b>show nfpp icmp-guard summary</b> | Displays the configuration. |

**Platform** N/A

**Description**

## 11.39 icmp-guard monitor-period

Use this command to configure the monitor time. Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard monitor-period** *seconds*

**no icmp-guard monitor-period**

**default icmp-guard monitor-period**

| Parameter<br>Description | Parameter      | Description                                                    |
|--------------------------|----------------|----------------------------------------------------------------|
|                          | <i>seconds</i> | Sets the monitor time, in the range from 180 to 86400 seconds. |

**Defaults** The default is 600.

**Command Mode** NFPP configuration mode.

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration Examples** The following example sets the monitor time to 180 seconds.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard monitor-period 180
```

| Related<br>Commands | Command                             | Description                       |

|                     | <b>show nfpp icmp-guard summary</b> | Displays the configuration.       |
|                     | <b>show nfpp icmp-guard hosts</b>   | Displays the monitored host list. |
|                     | <b>clear nfpp icmp-guard hosts</b>  | Clears the isolated host.         |

**Platform** N/A

**Description**

## 11.40 icmp-guard rate-limit

Use this command to set the rate-limit threshold globally. Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard rate-limit** { **per-src-ip** | **per-port** } *pps*

**no icmp-guard rate-limit** { **per-src-ip** | **per-port** }

**default icmp-guard rate-limit** { **per-src-ip** | **per-port** }

### Parameter Description

| Parameter         | Description                                        |
|-------------------|----------------------------------------------------|
| <b>per-src-ip</b> | Sets the rate limit for each source IP address.    |
| <b>per-port</b>   | Sets the rate limit for each port.                 |
| <i>pps</i>        | Sets the rate limit, in the range from 1 to 19999. |

### Defaults

The default settings are as follows:

For the 11.X CM supervisor module, the rate-limit thresholds for each source IP address and each port are 2000 pps and 4000 pps respectively.

For the 11.X CMII supervisor module, the rate-limit thresholds for each IP MAC address and each port are 2500 pps and 4500 pps respectively.

### Command Mode

NFPP configuration mode.

### Usage Guide

N/A

### Configuration Examples

The following example sets the rate-limit threshold globally.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard rate-limit per-src-ip 500
Ruijie(config-nfpp)# icmp-guard rate-limit per-port 800
```

### Related Commands

| Command                             | Description                                   |
|-------------------------------------|-----------------------------------------------|
| <b>nfpp icmp-guard policy</b>       | Sets the rate limit and the attack threshold. |
| <b>show nfpp icmp-guard summary</b> | Displays the configuration.                   |

### Platform

### Description

## 11.41 icmp-guard trusted-host

Use this command to set the trusted hosts free form monitoring. Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard trusted-host** *ip mask*

**no icmp-guard trusted-host { all | ip mask }**  
**default icmp-guard trusted-host**

**Parameter  
Description**

| Parameter   | Description                                     |
|-------------|-------------------------------------------------|
| <i>ip</i>   | Sets the IP address.                            |
| <i>mask</i> | Sets the IP mask.                               |
| <b>all</b>  | Deletes the configuration of all trusted hosts. |

**Defaults** No trusted host is configured by default.

**Command Mode** NFPP configuration mode.

**Usage Guide** The administrator can use this command to set the trusted host free from monitoring. The ICMP packets are allowed to send to the trusted host CPU without any rate-limit and warning configuration. Configure the mask to set all hosts in one network segment free from monitoring. UP to 500 trusted hosts are supported.

**Configuration** The following example sets the trusted hosts free form monitoring.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard trusted-host 1.1.1.0 255.255.255.0
```

**Related  
Commands**

**Description**

## 11.42 ip-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs. Use the **no** or **default** form of this command to restore the default setting.

**ip-guard attack-threshold { per-src-ip | per-port } pps**  
**no ip-guard attack-threshold { per-src-ip | per-port }**  
**default ip-guard attack-threshold { per-src-ip | per-port }**

**Parameter  
Description**

| Parameter         | Description                                           |
|-------------------|-------------------------------------------------------|
| <b>per-src-ip</b> | Sets the attack threshold for each source IP address. |
| <b>per-port</b>   | Sets the attack threshold for each port.              |

|            |                                                                   |
|------------|-------------------------------------------------------------------|
| <i>pps</i> | Sets the attack threshold, in pps. The valid range is 1 to 19999. |
|------------|-------------------------------------------------------------------|

**Defaults** By default, the attack threshold for each source IP address and each port are 200pps and 400pps respectively.

**Command** NFPP configuration mode.  
**Mode**

**Usage Guide** The attack threshold shall be equal to or larger than the rate-limit threshold.

**Configuration** The following example sets the global attack threshold.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard attack-threshold per-src-ip 2
Ruijie(config-nfpp)# ip-guard attack-threshold per-port 50
```

**Description**

## 11.45 ip-guard monitor-period

Use this command to configure the monitor time. Use the **no** or **default** form of this command to restore the default setting.

**ip-guard monitor-period** *seconds*

**no ip-guard monitor-period**

**default ip-guard monitor-period**

**Parameter  
Description**

| Parameter      | Description                                                                   |
|----------------|-------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the monitor time, in the range from 180 to 86400 in the unit of seconds. |

**Defaults**

The default is 600.

**Command  
Mode**

NFPP configuration mode.

**Usage Guide**

When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software

**Configuration**

The following example sets the monitor time to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard monitor-period 180
```

**Related  
Commands**

**Description**

## 11.46 ip-guard monitored-host-limit

Use this command to set the maximum monitored host number. Use the **no** or **default** form of this

command to restore the default setting.

**ip-guard monitored-host-limit** *number*

**no ip-guard monitored-host-limit**

**default ip-guard monitored-host-limit**

**Parameter  
Description**

| Parameter     | Description                                                           |
|---------------|-----------------------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to 4294967295. |

**Defaults**

The default is 20000.

**Command  
Mode**

NFPP configuration mode

**Usage Guide**

If the monitored host number has reached the default 20000, the administrator shall set the max-number smaller than 20000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts. to remind the administrator of the invalid configuration and removing the monitored hosts.

When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_ARP\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20000 monitored hosts.to remind the administrator.

**Configuration**

The following example sets the maximum monitored host number to 200.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard monitored-host-limit 200
```

**Description**

## 11.47 ip-guard rate-limit

Use this command to set the rate-limit threshold globally. Use the **no** or **default** form of this command to restore the default setting.

**ip-guard rate-limit** { **per-src-ip** | **per-port** } *pps*

**no ip-guard rate-limit** { **per-src-ip** | **per-port** }

**default ip-guard rate-limit** {**per-src-ip** | **per-port** }

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                   |                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------|
| <b>per-src-ip</b> | <ul style="list-style-type: none"> <li>● Sets the rate limit for each source IP address.</li> </ul> |
| <b>per-port</b>   | <ul style="list-style-type: none"> <li>● Sets the rate limit for each port.</li> </ul>              |
| <i>pps</i>        | <ul style="list-style-type: none"> <li>● Sets the rate limit, in the range of 1 to 19999</li> </ul> |

**Defaults** By default, the the rate-limit threshold for each source IP address and each port is 20pps and 100pps respectively.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the rate-limit threshold globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard rate-limit per-src-ip 2
Ruijie(config-nfpp)# ip-guard rate-limit per-port 50
```

**Description**

## 11.48 ip-guard scan-threshold

Use this command to set the global scan threshold. Use the **no** or **default** form of this command to restore the default setting.

**ip-guard scan-threshold** *pkt-cnt*

**no ip-guard scan-threshold**

**default ip-guard scan-threshold**

**Parameter  
Description**

| Parameter      | Description                                            |
|----------------|--------------------------------------------------------|
| <i>pkt-cnt</i> | Sets the scan threshold, in the range from 1 to 19999. |

**Defaults** The default scan threshold is 100, in 10 seconds.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the global scan threshold to 20pps.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard scan-threshold 20
```

**Related  
Commands**

| Command                             | Description                          |
|-------------------------------------|--------------------------------------|
| <b>nfpp ip-guard scan-threshold</b> | Sets the scan threshold on the port. |

**Description**

## 11.49 ip-guard trusted-host

Use this command to set the trusted hosts free form monitoring. Use the **no** or **default** form of this command to restore the default setting.

**ip-guard trusted-host** *ip mask*

**no ip-guard trusted-host** { **all** | *ip mask* }

**default ip-guard trusted-host**

**Parameter  
Description**

| Parameter   | Description                                     |
|-------------|-------------------------------------------------|
| <i>ip</i>   | Sets the IP address.                            |
| <i>mask</i> | Sets the IP mask.                               |
| <b>all</b>  | Deletes the configuration of all trusted hosts. |

**Defaults** N/A.

**Command  
Mode** NFPP configuration mode.

**Usage Guide** The administrator can use this command to set the trusted host free from monitoring. The ICMP packets are allowed to sent to the trusted host CPU without any rate-limit and warning configuration. Configure the mask to set all hosts in one network segment free from monitoring. UP to 500 trusted hosts are supported.

**Configuration** The following example sets the trusted hosts free form monitoring.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard trusted-host 1.1.1.0 255.255.255.0
```

| <b>log-buffer entries</b> <i>number</i> | Sets the NFPP log buffer area size.                         |
| <b>show nfpp log summary</b>            | Displays the NFPP log configuration or the log buffer area. |

**Platform** N/A

**Description**

## 11.53 logging

Use this command to set the VLAN or the interface log for NFPP. Use the **no** or **default** form of this command to restore the default setting.

**logging vlan** *vlan-range*

**logging interface** *interface-id*

**no logging vlan** *vlan-range*

**no logging interface** *interface-id*

**default logging**

**Parameter  
Description**

| Parameter           | Description                                                    |
|---------------------|----------------------------------------------------------------|
| <i>vlan-range</i>   | Sets the specified VLAN range, in the format such as "1-3, 5". |
| <i>interface-id</i> | Sets the interface ID.                                         |

**Defaults** All logs are recorded by default.

**Command** NFPP configuration mode.  
**Mode**

**Usage Guide** Use this command to filter the logs and records the logs within the specified VLAN range or the specified port

**Configuration** The following example records the logs in VLAN 1,VLAN 2,VLAN 3 and VLAN 5 only.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# logging vlan 1-3,5
```

The following example records the logs on the interface GigabitEthernet 0/1 only.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# logging interface G 0/1
```

**Platform** N/A

**Description**

## 11.54 match

Use this command to specify the message matching filed for the user-defined anti-attack.

**match** [ *etype type* ] [ **src-mac** *smac* [ **src-mac-mask** *smac\_mask* ] ] [ **dst-mac** *dmac* [ **dst-mac-mask** *dst\_mask* ] ] [ **protocol** *protocol* ] [ **src-ip** *sip* [ **src-ip-mask** *sip-mask* ] ] [ **src-ipv6** *sip6* [ **src-ipv6-masklen** *sip6-masklen* ] ] [ **dst-ip** *dip* [ **dst-ip-mask** *dip-mask* ] ] [ **dst-ipv6** *dip6* [ **dst-ipv6-masklen** *dip6-masklen* ] ] [ **src-port** *sport* ] [ **dst-port** *dport* ]

**Parameter  
Description**

| Parameter           | Description                                  |
|---------------------|----------------------------------------------|
| <i>type</i>         | Ethernet link layer packet type              |
| <i>smac</i>         | Source MAC address                           |
| <i>smac_mask</i>    | Source MAC address mask                      |
| <i>dmac</i>         | Destination MAC address                      |
| <i>dmac_mask</i>    | Destination MAC address mask                 |
| <i>protocol</i>     | IPv4/v6 message protocol                     |
| <i>sip</i>          | Source IPv4 address                          |
| <i>sip_mask</i>     | Source IPv4 address mask                     |
| <i>sip6</i>         | Source IPv6 address                          |
| <i>sip6_masklen</i> | Source IPv6 address mask                     |
| <i>dip</i>          | Destination IPv4 address                     |
| <i>dip_mask</i>     | Destination IPv4 address mask                |
| <i>dip6</i>         | Destination IPv6 address                     |
| <i>dip6_masklen</i> | Length of the destination IPv6 address mask. |
| <i>sport</i>        | Source port                                  |

|              |                  |
|--------------|------------------|
| <i>dport</i> | Destination port |
|--------------|------------------|

**Defaults** N/A

**Command Mode** NFPP configuration mode.

**Usage Guide** Use this command to create a new user-defined anti-attack type and specify the message fields to be matched.

**Configuration Examples** The following example specifies the message matching field for the user-defined anti-attack.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nfpp define tcp
Ruijie(config-nfpp-define)#match etype 0x0800 protocol 0x06
```

| <b>show nfpp define summary</b> | Displays the user-defined anti-attack configuration |

**Platform Description** N/A

## 11.55 monitored-host-limit

Use this command to set the maximum monitored host number. Use the **no** or **default** form of this command to restore the default setting.

**monitored-host-limit** *number*

**no monitored-host-limit**

**default monitored-host-limit**

**Parameter Description**

| Parameter     | Description                                                           |
|---------------|-----------------------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to 4294967295. |

**Defaults** The default is 20000.

**Command Mode** NFPP define configuration mode

**Usage Guide** If the monitored host number has reached the default 20000, the administrator shall set the max-number smaller than 20000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts. to

remind the administrator of the invalid configuration and removing the monitored hosts.

When the maximum monitored host number has been exceeded, it prompts the message that % %  
NFPP\_DEFINE-4-SESSION\_LIMIT: Attempt to exceed limit of name's 20000 monitored hosts. to  
remind the administrator

**Configuration** The following example sets the maximum monitored host number.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nfpp define tcp
Ruijie(config-nfpp-define)#monitored-host-limit 500
```

**Related  
Commands**

| Command                         | Description                                         |
|---------------------------------|-----------------------------------------------------|
| <b>show nfpp define summary</b> | Displays the user-defined anti-attack configuration |

**Platform** N/A

**Description**

## 11.56 monitor period

Use this command to set the monitoring time. Use the **no** or **default** form of this command to restore the default setting.

**monitor-period** *seconds*

**no monitor-period**

**default monitor-period**

**Parameter  
Description**

| Parameter      | Description                                                                   |
|----------------|-------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the monitor time, in the range from 180 to 86400 in the unit of seconds. |

**Defaults** The default is 600.

**Command  
Mode** NFPP define configuration mode.

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.  
If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration** The following example sets the monitoring time to 1000 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# define tcp
Ruijie(config-nfpp-define)#monitor-period 1000
```

**Description**

## 11.57 nd-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs. Use the **no** or **default** form of this command to restore the default setting.

**nd-guard attack-threshold per-port { ns-na | rs | ra-redirect } pps**

**no nd-guard attack-threshold per-port { ns-na | rs | ra-redirect }**

**default nd-guard attack-threshold per-port { ns-na | rs | ra-redirect }**

**Parameter  
Description**

| Parameter          | Description                                                                     |
|--------------------|---------------------------------------------------------------------------------|
| <b>ns-na</b>       | Sets the neighbor request and neighbor advertisement.                           |
| <b>rs</b>          | Sets the router request.                                                        |
| <b>ra-redirect</b> | Sets the router advertisement and the redirect packets.                         |
| <i>pps</i>         | Sets the attack threshold, in the range from 1 to 19999 in the unit of seconds. |

**Defaults**

By default, the default attack threshold for the ns-na, rs and ra-redirect on each port is 5000, 1000 and 1000 respectively.

**Command**

NFPP configuration mode.

**Mode****Usage Guide**

The attack threshold shall be equal to or larger than the rate-limit threshold.

**Configuration**

The following example sets the global attack threshold.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nd-guard attack-threshold per-port ns-na 20
Ruijie(config-nfpp)# nd-guard attack-threshold per-port rs 10
Ruijie(config-nfpp)# nd-guard attack-threshold per-port ra-redirect 10
```

**Description**

## 11.60 nd-guard ratelimit-forwarding enable

Use this command to enable the ND-guard ratelimit-forwarding on the interface.

**nd-guard ratelimit-forwarding enable**

Use this command to disable the ND-guard ratelimit-forwarding on the interface.

**no nd-guard ratelimit-forwarding enable**

Use this command to restore the default setting.

**default nd-guard ratelimit-forwarding enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** The function is enabled by default.

**Command Mode** NFPP configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example enables the ND-guard ratelimit-forwarding on the interface.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nd-guard ratelimit-forwarding enable
```

**Platform Description** N/A

## 11.61 nfpp

Use this command to enter NFPP configuration mode.

**nfpp**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** Use this command to enter NFPP configuration mode and make further configuration.

**Configuration Examples**

```
Ruijie(config)# nfpp
```

**Platform Description** N/A

## 11.62 nfpp arp-guard enable

Use this command to enable the anti-ARP attack function on the interface. Use the **no** or **default** form of this command to restore the default setting.

**nfpp arp-guard enable**

**no nfpp arp-guard enable**

**default nfpp arp-guard enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** The anti-ARP attack function is not enabled on the interface.

**Command Mode** Interface configuration mode.

**Usage Guide** The interface anti-ARP attack configuration is prior to the global configuration.

**Configuration Examples** The following example enables the anti-ARP attack function on the interface.

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp arp-guard enable
```

| Related<br>Commands | Command                            | Description                           |

|                     | <b>arp-guard enable</b>            | Enables the anti-ARP attack function. |
|                     | <b>show nfpp arp-guard summary</b> | Displays the configuration.           |

**Platform** N/A

**Description**

## 11.63 nfpp arp-guard isolate-period

Use this command to set the isolate period in the interface configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**nfpp arp-guard isolate-period { seconds | permanent }**

**no nfpp arp-guard isolate-period**

**default nfpp arp-guard isolate-period**

| Parameter<br>Description | Parameter      | Description                                                                                       |
|--------------------------|----------------|---------------------------------------------------------------------------------------------------|
|                          | <i>seconds</i> | Sets the isolate period. The value is 0, or in the range from 30 to 86400 in the unit of seconds. |

|                  |                      |
|------------------|----------------------|
| <b>permanent</b> | Permanent isolation. |
|------------------|----------------------|

**Defaults** By default, the isolate period is not configured.

**Command Mode** Interface configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the isolate period in the interface configuration mode.

**Examples**

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp arp-guard isolate-period 180
```

| <b>Related Commands</b> | Command                            | Description                     |

**Platform** N/A

**Description**

## 11.64 nfpp arp-guard policy

Use this command to set the rate-limit threshold and the attack threshold. Use the **no** or **default** form of this command to restore the default setting.

**nfpp arp-guard policy { per-src-ip | per-src-mac | per-port } rate-limit-pps attack-threshold-pps**

**no nfpp arp-guard policy { per-src-ip | per-src-mac | per-port }**

**default nfpp arp-guard policy { per-src-ip | per-src-mac | per-port }**

| <b>Parameter Description</b> | Parameter                   | Description                                                                         |
|------------------------------|-----------------------------|-------------------------------------------------------------------------------------|
|                              | <b>per-src-ip</b>           | Sets the rate-limit threshold and the attack threshold for each source IP address.  |
|                              | <b>per-src-mac</b>          | Sets the rate-limit threshold and the attack threshold for each source MAC address. |
|                              | <b>per-port</b>             | Sets the rate-limit threshold and the attack threshold for each port.               |
|                              | <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range from 1 to 19999.                        |
|                              | <i>attack-threshold-pps</i> | Sets the attack threshold, in the range from 1 to 19999.                            |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command Mode** Interface configuration mode.

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp arp-guard policy per-src-ip 2 10
Ruijie(config-if)# nfpp arp-guard policy per-src-mac 3 10
Ruijie(config-if)# nfpp arp-guard policy per-port 50 100
```

**Description**

## 11.66 nfpp define enable

Use this command to enable the user-defined anti-attack function on the interface. Use the **no** or **default** form of this command to restore the default setting.

**nfpp define** *name* **enable**

**no nfpp define** *name* **enable**

**default nfpp define** *name* **enable**

| Parameter<br>Description | Parameter   | Description                               |
|--------------------------|-------------|-------------------------------------------|
|                          | <i>name</i> | Name of the user-defined anti-attack type |

**Defaults** N/A

**Command Mode** Interface configuration mode.

**Usage Guide** This command takes effect only after the name of the user-defined anti-attack and the match, rate-count, rate-limit and the attack-threshold have been configured.

**Configuration Examples** The following example enables the user-defined anti-attack function on the interface.

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp define tcp enable
```

| Related<br>Commands | Command                         | Description                                         |

**Description**

## 11.67 nfpp define policy

Use this command to set the local rate-limit threshold and the attack threshold. Use the **no** or **default** form of this command to restore the default setting.

**nfpp define** *name* **policy** { **per-src-ip** | **per-src-mac** | **per-port** } *rate-limit-pps* *attack-threshold-pps*

**no nfpp define** *name* **policy** {**per-src-ip** | **per-src-mac** | **per-port**}

**default nfpp define** *name* **policy** { **per-src-ip** | **per-src-mac** | **per-port** }

### Parameter Description

| Parameter                   | Description                                                  |
|-----------------------------|--------------------------------------------------------------|
| <b>per-src-ip</b>           | Sets the attack threshold for each source IP address.        |
| <b>per-src-mac</b>          | Sets the attack threshold for each source MAC address.       |
| <b>per-port</b>             | Sets the attack threshold for each port.                     |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range from 1 to 19999. |
| <i>attack-threshold-pps</i> | Sets the attack threshold, in the range of from1 to 19999.   |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command Mode** Interface configuration mode.

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration Examples** The following example sets the local rate-limit threshold and the attack threshold.

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp define tcp policy per-src-ip 2 10
Ruijie(config-if)# nfpp define tcp policy per-port 50 100
```

|-------------------------------------|---------------------------------------|
| <b>dhcp-guard enable</b>            | Enables the anti-ARP attack function. |
| <b>show nfpp dhcp-guard summary</b> | Displays the configuration.           |

**Platform  
Description** N/A

## 11.69 nfpp dhcp-guard isolate-period

Use this command to set the isolate period in the interface configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**nfpp dhcp-guard isolate-period { seconds | permanent }**

**no nfpp dhcp-guard isolate-period**

**default nfpp dhcp-guard isolate-period**

**Parameter  
Description**

| Parameter        | Description                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------|
| <i>seconds</i>   | Sets the isolate period. The value is 0 or in the range from 30 to 86400 in the unit of seconds. |
| <b>permanent</b> | Permanent isolation.                                                                             |

**Defaults** By default, the isolate period is not configured

**Command  
Mode** Interface configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the isolate period to 180 seconds.

**Examples**

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp dhcp-guard isolate-period 180
```

**Related  
Commands**

| Command                             | Description                     |
|-------------------------------------|---------------------------------|
| <b>dhcp-guard isolate-period</b>    | Sets the global isolate period. |
| <b>show nfpp dhcp-guard summary</b> | Displays the configuration.     |

**Platform** N/A

**Description**

## 11.70 nfpp dhcp-guard policy

Use this command to set the rate-limit threshold and the attack threshold on the port. Use the **no** or **default** form of this command to restore the default setting.

**nfpp dhcp-guard policy { per-src-mac | per-port } rate-limit-pps attack-threshold-pps**

**no nfpp dhcp-guard policy { per-src-mac | per-port }**

**default nfpp dhcp-guard policy { per-src-mac | per-port }**

**Parameter  
Description**

| Parameter                   | Description                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------|
| <b>per-src-mac</b>          | Sets the rate-limit threshold and the attack threshold for the designated source MAC address. |
| <b>per-port</b>             | Sets the rate-limit threshold and the attack threshold for the designated port.               |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range from 1 to 19999.                                  |
| <i>attack-threshold-pps</i> | Sets the attack threshold, in the range from 1 to 19999.                                      |

**Defaults** The rate-limit threshold and the attack threshold are not configured by default. So the device adopts the rate-limit threshold and the attack threshold that are set in the global configuration mode.

**Command** Interface configuration mode.

**Mode**

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold on interface G0/1.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp dhcpv6-guard policy per-src-mac 3 10
Ruijie(config-if)# nfpp dhcpv6-guard policy per-port 50 100
```

Description

## 11.71 nfpp dhcpv6-guard enable

Use this command to enable the DHCPv6 anti-attack function on the interface. Use the **no** or **default** form of this command to restore the default setting.

**nfpp dhcpv6-guard enable**

**no nfpp dhcpv6-guard enable**

**default nfpp dhcpv6-guard enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** The DHCPv6 anti-attack function is not enabled on the interface.

**Command Mode** Interface configuration mode.

**Usage Guide** The interface DHCPv6 anti- attack configuration is prior to the global configuration.

**Configuration Examples** The following example enables the DHCPv6 anti-attack function on interface G0/1.

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp dhcpv6-guard enable
```

| Related<br>Commands | Command                               | Description                           |

Description

## 11.72 nfpp dhcpv6-guard policy

Use this command to set the rate-limit threshold and the attack threshold. Use the **no** or **default** form of this command to restore the default setting.

```

nfpp dhcpv6-guard policy { per-src-mac | per-port } rate-limit-pps attack-threshold-pps
no nfpp dhcpv6-guard policy { per-src-mac | per-port }
default nfpp dhcpv6-guard policy { per-src-mac | per-port }

```

**Parameter  
Description**

| Parameter                   | Description                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------|
| <b>per-src-mac</b>          | Sets the rate-limit threshold and the attack threshold for each source MAC address. |
| <b>per-port</b>             | Sets the rate-limit threshold and the attack threshold for each port.               |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range of from 1 to 19999.                     |
| <i>attack-threshold-pps</i> | Sets the attack threshold, in the range from 1 to 19999.                            |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command Mode** Interface configuration mode.

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold.

**Examples**

```

Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp dhcpv6-guard policy per-src-mac 3 10
Ruijie(config-if)# nfpp dhcpv6-guard policy per-port 50 100

```

## 11.74 nfpp icmp-guard isolate-period

Use this command to set the isolate period in the interface configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**nfpp icmp-guard isolate-period { seconds | permanent }**

**no nfpp icmp-guard isolate-period**

**default nfpp icmp-guard isolate-period**

| Parameter<br>Description | Parameter        | Description                                                                                      |
|--------------------------|------------------|--------------------------------------------------------------------------------------------------|
|                          | <i>seconds</i>   | Sets the isolate period. The value is 0 or in the range from 30 to 86400 in the unit of seconds. |
|                          | <b>permanent</b> | Permanent isolation.                                                                             |

**Defaults** By default, the isolate period is not configured.

**Command Mode** Interface configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the isolate period in the interface configuration mode.

**Examples**

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp icmp-guard isolate-period 180
```

| Related<br>Commands | Command                             | Description                     |

**Description**

## 11.78 nfpp ip-guard policy

Use this command to set the rate-limit threshold and the attack threshold. Use the **no** or **default** form of this command to restore the default setting.

```

nfpp ip-guard policy { per-src-ip | per-port } rate-limit-pps attack-threshold-pps
no nfpp ip-guard policy { per-src-ip | per-port }
default nfpp ip-guard policy { per-src-ip | per-port }

```

| Parameter<br>Description | Parameter             | Description                                                                        |
|--------------------------|-----------------------|------------------------------------------------------------------------------------|
|                          | <b>per-src-ip</b>     | Sets the rate-limit threshold and the attack threshold for each source IP address. |
|                          | <b>per-port</b>       | Sets the rate-limit threshold and the attack threshold for each port.              |
|                          | <i>rate-limit-pps</i> | Sets the rate-limit threshold, in the range from 1 to 19999.                       |

*attack-threshold-pps*

Sets the attack threshold, in the range from 1 to 19999.

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command Mode** Interface configuration mode.

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp ip-guard policy per-src-ip 2 10
Ruijie(config-if)# nfpp ip-guard policy per-port 50 100
```

**Description**

## 11.79 nfpp ip-guard scan-threshold

Use this command to set the scan threshold. Use the **no** or **default** form of this command to restore the default setting.

**nfpp ip-guard scan-threshold** *pkt-cnt*

**no nfpp ip-guard scan-threshold**

**default nfpp ip-guard scan-threshold**

**Parameter Description**

| Parameter      | Description                                            |
|----------------|--------------------------------------------------------|
| <i>pkt-cnt</i> | Sets the scan threshold, in the range from 1 to 19999. |

**Defaults** By default, the sport-based scan threshold is not configured.

**Command Mode** Interface configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the scan threshold to 20pps.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp ip-guard scan-threshold 20
```

**Platform** N/A

**Description**

## 11.81 nfpp nd-guard policy

Use this command to set the rate-limit threshold and the attack threshold. Use the **no** or **default** form of this command to restore the default setting.

**nfpp nd-guard policy per-port** { **ns-na** | **rs** | **ra-redirect** } *rate-limit-pps attack-threshold-pps*

**no nfpp nd-guard policy per-port** { **ns-na** | **rs** | **ra-redirect** }

**default nfpp nd-guard policy per-port** { **ns-na** | **rs** | **ra-redirect** }

| Parameter Description | Parameter             | Description                                                  |
|-----------------------|-----------------------|--------------------------------------------------------------|
|                       | <b>ns-na</b>          | Sets the neighbor request and neighbor advertisement.        |
|                       | <b>rs</b>             | Sets the router request.                                     |
|                       | <b>ra-redirect</b>    | Sets the router advertisement and the redirect packets.      |
|                       | <i>rate-limit-pps</i> | Sets the rate-limit threshold, in the range from 1 to 19999. |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command** Interface configuration mode.  
**Mode**

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp nd-guard policy per-port ns-na 50 100
Ruijie(config-if)# nfpp nd-guard policy per-port rs 10 20
Ruijie(config-if)# nfpp nd-guard policy per-port ra-redirect 10 20
```

**Description**

## 11.82 show nfpp arp-guard hosts

Use this command to display the monitored host.

**show nfpp arp-guard hosts** [ **statistics** ] [ [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* | *mac-address* ] ] ]

| Parameter<br>Description | Parameter                 | Description                                                 |
|--------------------------|---------------------------|-------------------------------------------------------------|
|                          | <code>statistics</code>   | Displays the statistical information of the monitored host. |
|                          | <code>vid</code>          | The VLAN ID                                                 |
|                          | <code>interface-id</code> | The interface name                                          |
|                          | <code>ip-address</code>   | The IP address                                              |
|                          | <code>mac-address</code>  | The MAC address                                             |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration** The following example displays the statistical information of the monitored host.

**Examples**

```
Ruijie# show nfpp arp-guard hosts statistics
success    fail    total
-----
100         20      120

The following example shows the monitored host:
Ruijie# show nfpp arp-guard hosts
If column 1 shows '*', it means "hardware do not isolate user" .
VLAN  interface IP address  MAC address  remain-time(s)
----  -
1      Gi0/1      1.1.1.1      -            110

**Platform** N/A

**Description**

## 11.85 show nfpp define hosts

Use this command to display the monitored hosts.

**show nfpp define hosts** *name* [ **statistics** ] [ [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* ] ]

**Parameter Description**

| Parameter           | Description                                 |
|---------------------|---------------------------------------------|
| <i>name</i>         | Name of the user-defined anti-attack type.  |
| <b>statistics</b>   | Displays the statistics of monitored hosts. |
| <i>vid</i>          | Vlan ID.                                    |
| <i>interface-id</i> | Interface name.                             |
| <i>ip-address</i>   | IP address.                                 |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** This command allows filtering the hosts with parameters specified

**Configuration** The following example displays the monitored hosts.

**Examples**

```
Ruijie#show nfpp define hosts abc
If col_filter 1 shows '*', it means "hardware do not isolate host".
VLAN      interface  MAC address    remain-time(s)
-----
*1         Gi4/2        00d0.f822.33e5  592
Total: 1 host
```

**Description**

## 11.86 show nfpp define summary

Use this command to display the configuration.

**show nfpp define summary** [ *name* ]

| <b>Parameter Description</b> | Parameter   | Description                                |
|------------------------------|-------------|--------------------------------------------|
|                              | <i>name</i> | Name of the user-defined anti-attack type. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** This command can be used to display the configuration. Without the name specified, all user-defined anti-attack types will be displayed.

**Configuration** The following example displays the configuration.

### Examples

```
Ruijie#show nfpp define summary abc
Define abc summary:
match etype 0x800 src-ip 1.1.1.1 src-ip-mask 255.255.255.255
Maximum count of monitored hosts: 20000
Monitor period:600s
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status Rate-limit Attack-threshold
Global Disable -/10/- -/20/-
Gi4/1 Enable -/-/- -/-/-
```

| Field     | Description                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------|
| Interface | If the interface field is displayed as Global, it means that is configured in the global configuration mode. |
| Status    | Enables/ Disables the anti-attack function.                                                                  |

| <b>Related Commands</b> | Command      | Description                                |

|-----------------------------|--------------------------------------------|
|                             | anti-attack type.                          |
| <b>policy</b>               | Attack threshold and rate-limit threshold. |
| <b>isolate-period</b>       | Isolates time                              |
| <b>monitored-period</b>     | Monitored time                             |
| <b>monitored-host-limit</b> | Maximum monitored host number              |

**Platform** N/A

**Description**

## 11.87 show nfpp define trusted-host

Use this command to display the trusted host free from monitoring.

**show nfpp define trusted-host** *name*

| Parameter<br>Description | Parameter   | Description                                |
|--------------------------|-------------|--------------------------------------------|
|                          | <i>name</i> | Name of the user-defined anti-attack type. |

**Defaults** N/A.

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration** The following example displays the trusted host configuration.

**Examples**

```
Ruijie# show nfpp define trusted-host tcp
Define tcp:
IP address      mask
-----
1.1.1.0         255.255.255.0
1.1.2.0         255.255.255.0
Total:2 record(s)
```

**Description**

## 11.88 show nfpp dhcp-guard hosts

Use this command to display the monitored host.

**show nfpp dhcp-guard hosts** [ **statistics** ] [ [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* | *mac-address* ] ] ]

| Parameter Description | Parameter           | Description                                                 |
|-----------------------|---------------------|-------------------------------------------------------------|
|                       | <b>statistics</b>   | Displays the statistical information of the monitored host. |
|                       | <i>vid</i>          | The VLAN ID.                                                |
|                       | <i>interface-id</i> | The interface name.                                         |
|                       | <i>ip-address</i>   | The IP address.                                             |
|                       | <i>mac-address</i>  | The MAC address.                                            |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the statistical information of the monitored host.

```
Ruijie# show nfpp dhcp-guard hosts statistics
success    fail    total
-----    ----    -----
100         20      120
```

The following example shows the monitored host:

```
Ruijie# show nfpp dhcp-guard hosts
If column 1 shows '*', it means "hardware failed to isolate host".
VLAN interface MAC address remain-time(seconds)
----
1    gi0/2    0000.0000.0001    10
*2   gi0/1    0000.0000.0002    20
Total:2 host(s)
```

| Related Commands | Command                            | Description                |
|------------------|------------------------------------|----------------------------|
|                  | <b>clear nfpp dhcp-guard hosts</b> | Clears the monitored host. |

**Platform Description** N/A

## 11.89 show nfpp dhcp-guard summary

Use this command to display the configuration.

**show nfpp dhcp-guard summary**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration** The following example displays the configuration.

### Examples

```
Ruijie# show nfpp dhcp-guard summary
(Format of column Rate-limit and Attack-threshold is

**Description**

## 11.90 show nfpp dhcpv6-guard hosts

Use this command to display the monitored host.

**show nfpp dhcpv6-guard hosts** [ **statistics** ] [ [ *vlan vid* ] [ **interface** *interface-id* ] [ *ip-address* | *mac-address* ] ]

| Parameter<br>Description | Parameter           | Description                                                 |
|--------------------------|---------------------|-------------------------------------------------------------|
|                          | <b>statistics</b>   | Displays the statistical information of the monitored host. |
|                          | <i>vid</i>          | The VLAN ID.                                                |
|                          | <i>interface-id</i> | The interface name.                                         |
|                          | <i>ip-address</i>   | The IP address.                                             |
|                          | <i>mac-address</i>  | The MAC address.                                            |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration** The following example displays the statistical information of the monitored host.

**Examples**

```
Ruijie# show nfpp dhcpv6-guard hosts
If column 1 shows '*', it means "hardware failed to isolate host".
VLAN  interface  MAC address    remain-time(seconds)
----  -
*1    gi0/2      0000.0000.0001    10
*2    gi0/1      0000.0000.0002    20
Total:2 host(s)
```

**Platform** N/A

**Description**

## 11.97 show nfpp ip-guard trusted-host

Use this command to display the trusted host free from being monitored.

**show nfpp ip-guard summary**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration** The following example displays the trusted host free from being monitored.

#### Examples

```
Ruijie# show nfpp ip-guard trusted-host
IP address      mask
-----
1.1.1.0         255.255.255.0
1.1.2.0         255.255.255.0
```

```
Total.2 record(s)
```

**Related Commands**

|------------------------------|------------------------|
| <b>ip-guard trusted-host</b> | Sets the trusted host. |

**Platform** N/A**Description**

## 11.98 show nfpp log

Use this command to display the NFPP log configuration.

**show nfpp log summary**

Use this command to display the NFPP log buffer area content.

**show nfpp log buffer [ statistics ]****Parameter Description**

| Parameter         | Description                                                       |
|-------------------|-------------------------------------------------------------------|
| <b>statistics</b> | Displays the statistical information of the NFPP log buffer area. |

**Defaults** N/A**Command Mode** Privileged EXEC mode

**Usage Guide** When the log buffer area is full, the subsequent logs are to be dropped, and an entry with all attributes "-" is displayed in the log buffer area. The administrator shall increase the capacity of the log buffer area or improve the rate of generating the syslog.

The generated syslog in the log buffer area carries with the timestamp, for example:  
 %NFPP\_ARP\_GUARD-4-DOS\_DETECTED:  
 Host<IP=N/A,MAC=0000.0000.0004,port=Gi4/1,VLAN=1> was detected.(2009-07-01 13:00:00)

**Configuration** The following example displays the NFPP log configuration.**Examples**

```
Ruijie#show nfpp log summary
Total log buffer size : 10
Syslog rate : 1 entry per 2 seconds
Logging:
VLAN 1-3, 5
interface Gi 0/1
interface Gi 0/2
```

The following example displays the log number in the buffer area.

```
Ruijie#show nfpp log buffer statistics
There are 6 logs in buffer.
```

The following example shows the NFPP log buffer area:

```
Ruijie#show nfpp log buffer
```

| Protocol | VLAN | Interface | IP address | MAC address    | Reason         | Timestamp           |

#### Description

## 11.99 show nfpp nd-guard hosts

Use this command to display the monitored host.

**show nfpp nd-guard hosts** [**statistics** | **[[vlan vid] [interface interface-id]]**]

#### Parameter Description

| Parameter         | Description                                    |
|-------------------|------------------------------------------------|
| <b>statistics</b> | Displays the statistics of the monitored host. |
| <i>vid</i>        | Sets the VLAN ID.                              |

|                     |                                     |
|---------------------|-------------------------------------|
| <i>interface-id</i> | Sets the interface name and number. |
|---------------------|-------------------------------------|

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the statistics of the host monitored by ND-guard.

```
Ruijie#show nfpp nd-guard hosts statistics
```

```
success    fail    total
```

```
-----
```

```
10         2      12
```

The following example displays the host monitored by ND-guard. The "remain-time(s)" refers to the remaining time of isolation.

```
Ruijie#show nfpp nd-guard hosts
```

If col\_filter 1 shows '\*', it means "hardware do not isolate host".

```
VLAN      interface  ND-guard      remain-time(s)
```

```

| <b>nfpp nd-guard policy</b>      | Sets the rate-limit threshold and attack threshold.   |

**Platform** N/A

**Description**

## 11.101 trusted-host

Use this command to set the trusted hosts free form monitoring. Use the no form of this command to restore the default setting,

**trusted-host** { *mac mac\_mask* | *ip mask* | *IPv6/prefixlen* }

**no trusted-host** { **all** | *ip mask* | *IPv6/prefixlen* }

**Parameter Description**

| Parameter       | Description          |
|-----------------|----------------------|
| <i>ip</i>       | Sets the IP address. |
| <i>mac</i>      | MAC address.         |
| <i>mac_mask</i> | MAC address mask.    |

|                       |                                                                                  |
|-----------------------|----------------------------------------------------------------------------------|
| <i>IPv6/prefixlen</i> | IPv6 address and mask length                                                     |
| <i>mask</i>           | IP mask.                                                                         |
| <b>all</b>            | Deletes the configuration of all trusted hosts with the no form of this command. |

**Defaults** N/A

**Command** NFPP define configuration mode.

**Mode**

**Usage Guide** The administrator can use this command to set the trusted host free from monitoring. The ICMP packets are allowed to sent to the trusted host CPU without any rate-limit and warning configuration. Configure the mask to set all hosts in one network segment free from monitoring. UP to 500 trusted hosts are supported. Before configuring the trusted-host, the match type must be configured. If the message type configured by the match is Ipv4, the Ipv6 trusted addresses are not allowed. In the same way, if the message type is IPv6, the IPv4 trusted addresses are not allowed.

**Configuration** The following example sets the trusted hosts free form monitoring.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# define tcp
Ruijie(config-nfpp-define)#trusted-host 1.1.1.1 255.255.255.255
```

## 12 Security-log Commands

### 12.1 security-log audit-enable

Use this command to enable security log auditing. Use the no form of this command to disable security log auditing.

**security-log audit-enable**

**no security-log audit-enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       |             |

**Defaults** The function is enabled by default.

**Command Mode** Global configuration mode

**Usage Guide** After enabling the security log auditing, the device will record key operations including account management, log event, system event, configuration change and security log event.

**Configuration Examples** The following example enables the security log auditing.

```
Ruijie# configure terminal
Ruijie(config)# security-log audit-enable
Ruijie(config)# end
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     |             |

**Platform Description** N/A

### 12.2 security-log data-store-items

Use this command to configure the max storage capacity of security log.

**security-log data-store-items num**

| Parameter   | Parameter | Description                                               |
|-------------|-----------|-----------------------------------------------------------|
| Description | num       | Local storage capacity. The max value varies with product |

|  |                                   |
|--|-----------------------------------|
|  | capability. The min value is 500. |
|--|-----------------------------------|

**Defaults** The max value varies with product capability.

**Command Mode** Global configuration mode

**Usage Guide** If the local storage space is insufficient, run this command to adjust the storage capacity.

**Configuration Examples** The following example configures the local storage capacity of security log as 5000.

```
Ruijie# configure terminal
Ruijie(config)# security-log data-store-items 5000
Ruijie(config)# end
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     |             |

**Platform Description** N/A

## 12.3 security-log delete

Use this command to delete all logs of key operations.

**security-log delete all**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       |             |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Run this command to delete all key operation logs.

**Configuration Examples** The following example deletes all key operation logs.

```
Ruijie# security-log delete all
```

| Related Commands | Command | Description |
|------------------|---------|-------------|

**Platform** N/A

**Description**

## 12.4 security-log data-store-days

Use this command to configure the local storage time of security log.

**security-log data-store-days** *day*

| Parameter   | Parameter  | Description                   |
|-------------|------------|-------------------------------|
| Description | <i>day</i> | Storage time, range: 1-66535. |

**Defaults** 180 days

**Command Mode** Global configuration mode

**Usage Guide** The security log is stored locally for 180 days by default. The log exceeds the time will be deleted.

**Configuration Examples** The following example configures the storage time as 300 days.

```
Ruijie# configure terminal
Ruijie(config)# security-log data-store-days 300
Ruijie(config)# end
```

| Related Commands | Command | Description |

**Platform** N/A

**Description**

## 12.5 security-log auto-vacuum-time

Use this command to configure the aging time of security log.

**security-log auto-vacuum-time** *hh:mm:ss*

| Parameter   | Parameter       | Description           |
|-------------|-----------------|-----------------------|
| Description | <i>hh:mm:ss</i> | hour: minute: second. |

**Defaults** 03:00:00 by default

**Command Mode** Global configuration mode

**Usage Guide** The device will check local log at 3 am each day. If any log exceeds the storage time, it will be deleted. Run this command to change the check time.

**Configuration** The following example configures the aging time as 5:05 am.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# security-log auto-vacuum-time 05:05:00
Ruijie(config)# end
```

Description

## 12.7 show security-log detail

Use this command to display the detailed log information which can be filtered by time, type, username, host name, etc.

```
show security-log detail { all | { from yyyy mm dd hh:mm:ss to yyyy mm dd hh:mm:ss } } [ log-type { SEC_LOG | ACC_MNT | LOGIN | SYS | CONFIG | OTHER } ] [ user username ] [ hostname hostname ] [ peerinfo peerinfo ] { [ order-by [ time | log-type ] { asc | desc } ] [ start-item integer1 end-item integer2 ] ] }
```

Use this command to export the detailed log information which can be filtered by time, type, username, host name, etc.

```
show security-log detail export { all | { from yyyy mm dd hh:mm:ss to yyyy mm dd hh:mm:ss } } [ log-type { SEC_LOG | ACC_MNT | LOGIN | SYS | CONFIG | OTHER } ] [ user username ] [ hostname hostname ] [ peerinfo peerinfo ] [ order-by [ time | log-type ] { asc | desc } ] [ start-item integer1 end-item integer2 ] ]
```

Use this command to display the log statistics which can be filtered by time, type, username, host name, etc.

```
show security-log detail stat { all | { from yyyy mm dd hh:mm:ss to yyyy mm dd hh:mm:ss } } [ log-type { SEC_LOG | ACC_MNT | LOGIN | SYS | CONFIG | OTHER } ] [ user username ] [ hostname hostname ] [ peerinfo peerinfo ]
```

| Parameter Description | Parameter         | Description                                                                                                                                                                                  |
|-----------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>yyyy mm dd</i> | Year month day                                                                                                                                                                               |
|                       | <i>hh:mm:ss</i>   | Hour: minute: second                                                                                                                                                                         |
|                       | <b>log-type</b>   | Log types:<br>1) SEC_LOG (security-log-event)<br>2) ACC_MNT (account-management)<br>3) LOGIN (login-event)<br>4) SYS (system-event)<br>5) CONFIG (configuration-changes)<br>6) OTHER (other) |
|                       | <i>username</i>   | Filtering condition: username (exact match)                                                                                                                                                  |
|                       | <i>hostname</i>   | Filtering condition: host name (exact match)                                                                                                                                                 |
|                       | <i>peerinfo</i>   | Filtering condition: device information, including alias, IP or combination                                                                                                                  |

|                 |                |
|-----------------|----------------|
|                 | (fuzzy match)  |
| <i>integer1</i> | Start position |
| <i>integer2</i> | End position   |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to search or export the detailed security log information.

**Configuration Examples** The following example searches the security log information of userA from 0:00 on October 10, 2019 to 24:00 on October 22, 2019, and sorts result in descending order of time. Only the first 20 records are displayed.

```
Ruijie# show security-log detail from 2019 10 10 00:00:00 to 2019 10 22 23:59:59 user userA order-by
time desc start-item 1 end-item 20

time, username, peerinfo, hostname, log-type: content

2019-10-22 10:00:03, ---, console, Ruijie, SEC_LOG: SECURITY_LOG enabled security log audit
configuration successfully

2019-10-22 10:00:02, admin, vty0(192.168.111.111), Ruijie, SEC_LOG: SECURITY_LOG disabled
security log audit configuration unsuccessfully

2019-10-22 10:00:02, admin, vty0(192.168.111.111), Ruijie, SEC_LOG: SECURITY_LOG deleted all
security log successfully

.....
```

The following example displays all security log information.

```
Ruijie# show security-log detail all

time, username, peerinfo, hostname, log-type: content

2019-10-22 10:00:02, admin, vty0(192.168.111.111), Ruijie, SEC_LOG: SECURITY_LOG deleted all
security log successfully

2019-10-22 10:00:02, admin, vty0(192.168.111.111), Ruijie, SEC_LOG: SECURITY_LOG disabled
security log audit configuration unsuccessfully

2019-10-22 10:00:03, ---, console, Ruijie, SEC_LOG: SECURITY_LOG enabled security log audit
configuration successfully

.....
```

The following example exports the security log information of userA from 0:00 on October 10, 2019 to

24:00 on October 22, 2019.

```
Ruijie# show security-log detail export from 2019 10 10 00:00:00 to 2019 10 22 23:59:59 user userA
Export file: tmp:mng/security_log/export_file/log_20191022_110410_535250.csv
```

Note: the user can run the copy command to download the file:

```
Ruijie#copy tmp:mng/security_log/export_file/log_20191022_110410_535250.csv
tftp://192.168.1.1/security_log.csv
```

The following example searches the security log statistics of userA from 0:00 on October 10, 2019 to 24:00 on October 22, 2019.

```
Ruijie# show security-log detail stat from 2019 10 10 00:00:00 to 2019 10 22 23:59:59 user userA
Count:555
```

## 12.8 show security-log config

Use this command to search the security log configuration.

### show security-log config

| Parameter              | Parameter                                                                                                                                                                                                   | Description |

## 12.9 show security-log statistics

Use this command to search the security log statistics.

### **show security-log statistics**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       |             |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Run this command to display security log statistics, including:

- Number of current logs: xxx
- Number of history logs: xxx in total, xxx were covered
- Number of aged los: xxx
- Last deleting record: xxx

**Configuration** The following example displays security log statistics.

**Examples**

```
Ruijie# show security-log statistics
Current storage record count: 9000
Historical record count: have written 11111, overwritten 1111
Aging record count: 1000
Last delete record: 2019-10-24 10:00:00 userA vty0(192.168.1.1) Ruijie
SEC_LOG: SECURITY_LOG deleted all security log successfully
```

**Platform** N/A

**Description**

## 12.10 show security-log info

Use this command to display security log statistics during processing.

### **show security-log info**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       |             |

**Defaults** N/A

**Command** Privileged EXEC mode  
**Mode**

**Usage Guide** This command is used to display the statistics during security log processing, including:  
Number of log received successfully: xxx, receive failures: xxx  
Number of buffered logs: xxx  
Number of logs stored in flash: xxx  
History sync flashes: xxx, sync failures: xxx  
Reason for last sync failure: xxx (not display if no failure)  
Next time to sync flash: HH:MM:SS

**Configuration** The following example displays security log statistics during processing.

**Examples**

```
Ruijie# show security-log info
Receive log count: 2000, err 1
Current cached record count: 1999
Current store-in-flash record count: 5000
Historital sync flash count: 100,err 1
Reason for last sync failure: Failed to sync security logs to file database.
Next time to sync flash: 11:11:11
```

**Platform** N/A

## 1.1 command ID table

For IDs used in the following commands, refer to the command ID table below:

| ID                   | Meaning                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID                   | Number of access list. Range:<br>Standard IP ACL: 1 to 99, 1300 to 1999<br>Extended IP ACL: 100 to 199, 2000 to 2699<br>Extended MAC ACL: 700 to 799<br>Extended expert ACL: 2700 to 2899                                                                                                                                                                           |
| name                 | ACL name                                                                                                                                                                                                                                                                                                                                                            |
| sn                   | ACL SN (products can be set according to the priority)                                                                                                                                                                                                                                                                                                              |
| start-sn             | Start sequence number                                                                                                                                                                                                                                                                                                                                               |
| inc-sn               | Sequence number increment                                                                                                                                                                                                                                                                                                                                           |
| deny                 | If matched, access is denied.                                                                                                                                                                                                                                                                                                                                       |
| permit               | If matched, access is permitted.                                                                                                                                                                                                                                                                                                                                    |
| port                 | Protocol number. For IPv6, this field can be IPv6, ICMP, TCP, UDP and numbers 0 to 255. For IPv4, it can be one of EIGRP, GRE, IPINIP, IGMP, NOS, OSPF, ICMP, UDP, TCP, AHP, ESP, PCP, PIM and IP, or it can be numbers 0 to 255 that represent the IP protocol. It is described when some important protocols, such as ICMP, TCP and UDP, are listed individually. |
| interface <i>idx</i> | Interface index                                                                                                                                                                                                                                                                                                                                                     |
| src                  | Packet source IP address (host address or network address)                                                                                                                                                                                                                                                                                                          |
| src-wildcard         | Source IP address wildcard. It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                                                                                                                                                       |
| src-ipv6-pfix        | Source IPv6 network address or network type                                                                                                                                                                                                                                                                                                                         |
| dst-ipv6-pfix        | Destination IPv6 network address or network type                                                                                                                                                                                                                                                                                                                    |
| pfix-len             | Prefix mask length                                                                                                                                                                                                                                                                                                                                                  |
| src-ipv6-addr        | Source IPv6 address                                                                                                                                                                                                                                                                                                                                                 |
| dst-ipv6-addr        | Destination IPv6 address                                                                                                                                                                                                                                                                                                                                            |
| dscp                 | Differential service code point, and code point value. Range: 0 to 63                                                                                                                                                                                                                                                                                               |
| flow-label           | Flow label in the range 0 to 1048575                                                                                                                                                                                                                                                                                                                                |
| dst                  | Packet destination IP address (host address or network address)                                                                                                                                                                                                                                                                                                     |
| dst-wildcard         | Destination IP address wildcard. It can be discontinuous, such as 0.255.0.32                                                                                                                                                                                                                                                                                        |
| fragment             | Packet fragment filtering.                                                                                                                                                                                                                                                                                                                                          |

|                                           |                                                                                                                                                                                                          |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>fragment-ipid</b> <i>fragment-ipid</i> | Fragment ID of the header in segmented packet                                                                                                                                                            |
| precedence                                | Packet precedence value (0 to 7)                                                                                                                                                                         |
| range                                     | The layer 4 port number range of the packet.                                                                                                                                                             |
| time-range <i>tm-rng-name</i>             | Time range of packet filtering, named <i>tm-rng-name</i>                                                                                                                                                 |
| tos                                       | Type of service (0 to 15)                                                                                                                                                                                |
| cos                                       | cos of service (0-7)                                                                                                                                                                                     |
| cos inner cos                             | cos of the packet tag                                                                                                                                                                                    |
| icmp-type                                 | ICMP message type (0 to 255)                                                                                                                                                                             |
| icmp-code                                 | ICMP message type code (0 to 255)                                                                                                                                                                        |
| icmp-message                              | ICMP message type name (0 to 255)                                                                                                                                                                        |
| operator port[port]                       | Operator (lt-smaller, eq-equal, gt-greater, neq-unequal, range-range)<br><i>port</i> indicates the port number. Dyadic operation needs two port numbers, while other operators only need one port number |
| src-mac-addr                              | Physical address of the source host                                                                                                                                                                      |
| dst-mac-addr                              | Physical address of the destination host                                                                                                                                                                 |
| VID vid                                   | VLAN ID                                                                                                                                                                                                  |
| VID inner vid                             | VID of the tag                                                                                                                                                                                           |
| ethernet-type                             | Ethernet protocol type. 0x value can be entered.                                                                                                                                                         |
| match-all <i>tcpf</i>                     | Match all bits of the TCP flag.                                                                                                                                                                          |
| established                               | Match the RST or ACK bit of the TCP flag.                                                                                                                                                                |
| <i>text</i>                               | Remark text                                                                                                                                                                                              |
| <i>in</i>                                 | Filter the incoming packets of the interface                                                                                                                                                             |
| <i>out</i>                                | Filter the outgoing packets of the interface                                                                                                                                                             |
| {rule mask offset} <sup>+</sup>           | rule: Hexadecimal value field; mask: Hexadecimal mask field<br>offset: Refer to the offset table<br>“+” sign indicates at least one group                                                                |
| log                                       | Output the matching syslog when the packet matches the ACL rule.                                                                                                                                         |

The fields in the packet are as follows:

AA AA AA AA AA AA BB BB BB BB BB BB CC CC DD DD  
DD DD EE FF GG HH HH HH II II JJ KK LL LL MM MM  
NN NN OO PP QQ QQ RR RR RR RR SS SS SS SS TT TT  
UU UU VV VV VV VV WW WW WW WW XY ZZ aa aa bb bb

The corresponding offset table is as follows:

| Letter | Meaning         | Offset | Letter | Meaning   | Offset |
|--------|-----------------|--------|--------|-----------|--------|
| A      | Destination MAC | 0      | O      | TTL field | 34     |

|   |                                               |    |    |                                    |    |
|---|-----------------------------------------------|----|----|------------------------------------|----|
| B | Source MAC                                    | 6  | P  | Protocol number                    | 35 |
| C | Data frame length field                       | 12 | Q  | IP check sum                       | 36 |
| D | VLAN tag field                                | 14 | R  | Source IP address                  | 38 |
| E | DSAP (Destination Service Access Point) field | 18 | S  | Destination IP address             | 42 |
| F | SSAP (Source Service Access Point) field      | 19 | T  | TCP source port                    | 46 |
| G | Ctrl field                                    | 20 | U  | TCP destination port               | 48 |
| H | Org Code field                                | 21 | V  | Sequence number                    | 50 |
| I | Encapsulated data type                        | 24 | W  | Confirmation field                 | 54 |
| J | IP version number                             | 26 | XY | IP header length and reserved bits | 58 |
| K | TOS field                                     | 27 | Z  | Reserved bits and flags bit        | 59 |
| L | Length of IP packet                           | 28 | a  | Windows size field                 | 60 |
| M | ID                                            | 30 | b  | Others                             | 62 |
| N | Flags field                                   | 32 |    |                                    |    |

The offsets of fields in the above table are their offsets in 802.3 data frames of SNAP+tag.

## 1.2 access-list

Use this command to create an access list to filter data packets. Use the **no** form of this command to remove the specified access list.

- Standard IP access list (1 to 99, 1300 to 1999)

```
access-list id { deny | permit } { source source-wildcard | host source | any | interface idx }
[time-range tm-range-name] [log]
```

- Extended IP access list (100 to 199, 2000 to 2699)

```
access-list id { deny | permit } protocol { source source-wildcard | host source | any | interface idx }
{ destination destination-wildcard | host destination | any } [ [ precedence precedence ] [ tos tos ] ]
[ dscp dscp ] [ ecn ecn ] [ fragment ] [ fragment-ipid fragment-ipid ] [ range lower upper ]
[ time-range time-range-name] [log]
```

- Extended MAC access list (700 to 799)

```
access-list id { deny | permit } { any | host source-mac-address | source-mac-address mask } { any |
host destination-mac-address | destination-mac-address mask } [ ethernet-type ] [ cos [ out ] [ inner in ] ]
```

- Extended expert access list (2700 to 2899)

```
access-list id { deny | permit } [ protocol | [ ethernet-type ] [ cos [ out ] [ inner in ] ] ] [ VID [ out ]
[ inner in ] ] { source source-wildcard | host source | any } { host source-mac-address | any }
{ destination destination-wildcard | host destination | any } { host destination-mac-address | any }
[ [ precedence precedence ] [ tos tos ] ] [ dscp dscp ] [ ecn ecn ] [ fragment ] [ fragment-ipid
fragment-ipid ] [ range lower upper ] [ [ udf udf-id header pos value mask ] ] [ int-flag-a ] [ int-flag-b ]
[ time-range time-range-name ]
```

- When you select the Ethernet-type field or cos field:

```
access-list id { deny | permit } [ ethernet-type | cos [ out ] [ inner in ] ] [ VID [ out ] [ inner in ] ] { source
source-wildcard | host source | any } { host source-mac-address | any } { destination
```

*destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [**udf** *udf-id header pos value mask*] [**time-range** *time-range-name*]

- When you select the protocol field:

**access-list** *id* { **deny** | **permit** } *protocol* [ **VID** [ *out* ] [ *inner in* ] ] { *source source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ [ **precedence** *precedence* ] [ **tos** *tos* ] ] [ **dscp** *dscp* ] [ **ecn** *ecn* ] ] [ **fragment** ] [ **fragment-ipid** *fragment-ipid* ] [ **range** *lower upper* ] [ [**udf** *udf-id header pos value mask*] ] [ *int-flag-a* ] [ *int-flag-b* ] ] [ **time-range** *time-range-name* ]

- Extended expert ACLs of some important protocols:

#### Internet Control Message Protocol (ICMP)

**access-list** *id* { **deny** | **permit** } **icmp** [ **VID** [ *out* ] [ *inner in* ] ] { *source source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ *icmp-type* ] [ [ *icmp-type* [ *icmp-code* ] ] ] [ *icmp-message* ] ] [ [ **precedence** *precedence* ] [ **tos** *tos* ] ] [ **dscp** *dscp* ] [ **ecn** *ecn* ] ] [ **fragment** ] [ **fragment-ipid** *fragment-ipid* ] [ **range** *lower upper* ] [ [**udf** *udf-id header pos value mask*] ] [ **time-range** *time-range-name* ]

#### Transmission Control Protocol (TCP)

**access-list** *id* { **deny** | **permit** } **tcp** [ **VID** [ *out* ] [ *inner in* ] ] { *source source-wildcard* | **host** *Source* | **any** } { **host** *source-mac-address* | **any** } [ **operator** *port* [ *port* ] ] { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ **operator** *port* [ *port* ] ] [ [ **precedence** *precedence* ] [ **tos** *tos* ] ] [ **dscp** *dscp* ] [ **ecn** *ecn* ] ] [ **fragment** ] [ **fragment-ipid** *fragment-ipid* ] [ **range** *lower upper* ] [ **time-range** *time-range-name* ] [ **match-all** *tcp-flag* | **established** ] [ [**udf** *udf-id header pos value mask*] ] [ *int-flag-a* ] [ *int-flag-b* ] ]

#### User Datagram Protocol (UDP)

**access-list** *id* { **deny** | **permit** } **udp** [ **VID** [ *out* ] [ *inner in* ] ] { *source source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } [ **operator** *port* [ *port* ] ] { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ **operator** *port* [ *port* ] ] [ [ **precedence** *precedence* ] [ **tos** *tos* ] ] [ **dscp** *dscp* ] [ **ecn** *ecn* ] ] [ **fragment** ] [ **fragment-ipid** *fragment-ipid* ] [ **range** *lower upper* ] [ [**udf** *udf-id header pos value mask*] ] [ *int-flag-a* ] [ *int-flag-b* ] ] [ **time-range** *time-range-name* ]

#### Virtual Extensible LAN(VXLAN):

**access-list** *id* { **deny** | **permit** } **vxlan** { **tcp** | **udp** } { *source source-wildcard* | **host** *source* | **any** } [ **eq** *port* ] { *destination destination-wildcard* | **host** *destination* | **any** } [ **eq** *port* ] [ **tagged** ] [ **udp-dport** *dport* ] [ **time-range** *time-range-name* ]

#### Parameter Description

| Parameter              | Description                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>id</i>              | Access list number. The ranges available are 1 to 99, 100 to 199, 1300 to 1999, 2000 to 2699, 2700 to 2899, and 700 to 799. |
| <b>deny</b>            | If not matched, access is denied.                                                                                           |
| <b>permit</b>          | If matched, access is permitted.                                                                                            |
| <i>source</i>          | Specify the source IP address (host address or network address).                                                            |
| <i>source-wildcard</i> | It can be discontinuous, for example, 0.255.0.32.                                                                           |

|                                               |                                                                                                                                                                                                                                                        |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>protocol</b>                               | IP protocol number. It can be one of EIGRP, GRE, IPINIP, IGMP, NOS, OSPF, ICMP, UDP, TCP, and IP. It can also be a number representing the IP protocol between 0 and 255. The important protocols such as ICMP, TCP, and UDP are described separately. |
| <i>destination</i>                            | Specify the destination IP address (host address or network address).                                                                                                                                                                                  |
| <i>destination-wildcard</i>                   | Wildcard of the destination IP address. It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                              |
| <b>fragment</b>                               | Packet fragment filtering                                                                                                                                                                                                                              |
| <b>fragment-ipid</b> <i>fragment-ipid</i>     | Fragment ID of the header in segmented packet                                                                                                                                                                                                          |
| <b>precedence</b>                             | Specify the packet priority.                                                                                                                                                                                                                           |
| <i>precedence</i>                             | Packet precedence value (0 to 7)                                                                                                                                                                                                                       |
| <b>range</b>                                  | Layer4 port number range of the packet.                                                                                                                                                                                                                |
| <i>lower</i>                                  | Lower limit of the layer4 port number.                                                                                                                                                                                                                 |
| <i>upper</i>                                  | Upper limit of the layer4 port number.                                                                                                                                                                                                                 |
| <b>time-range</b>                             | Time range of packet filtering                                                                                                                                                                                                                         |
| <i>time-range-name</i>                        | Time range name of packet filtering                                                                                                                                                                                                                    |
| <b>tos</b>                                    | Specify type of service.                                                                                                                                                                                                                               |
| <i>tos</i>                                    | ToS value (0 to 15)                                                                                                                                                                                                                                    |
| <b>dscp</b>                                   | Differentiated service code point                                                                                                                                                                                                                      |
| <i>dscp</i>                                   | Code point value, ranging from 0 to 63                                                                                                                                                                                                                 |
| <b>ecn</b>                                    | Specifies the congestion notification type.                                                                                                                                                                                                            |
| <i>ecn</i>                                    | Specifies the congestion notification type value (0 to 3).                                                                                                                                                                                             |
| <i>icmp-type</i>                              | ICMP message type (0 to 255)                                                                                                                                                                                                                           |
| <i>icmp-code</i>                              | ICMP message type code (0 to 255)                                                                                                                                                                                                                      |
| <i>icmp-message</i>                           | ICMP message type name                                                                                                                                                                                                                                 |
| <i>operator</i>                               | Operator (lt-smaller, eq-equal, gt-greater, neq-unequal, range-range)                                                                                                                                                                                  |
| <b>port</b> [ <i>port</i> ]                   | Port number; <i>range</i> needs two port numbers, while other operators only need one port number.                                                                                                                                                     |
| <b>host</b> <i>source-mac-address</i>         | Source physical address                                                                                                                                                                                                                                |
| <b>host</b><br><i>destination-mac-address</i> | Destination physical address                                                                                                                                                                                                                           |
| <b>VID</b> <i>vid</i>                         | Match the specified VID.                                                                                                                                                                                                                               |
| <i>ethernet-type</i>                          | Ethernet type                                                                                                                                                                                                                                          |
| <b>match-all</b>                              | Match all the bits of the TCP flag.                                                                                                                                                                                                                    |
| <i>tcp-flag</i>                               | Match the TCP flag.                                                                                                                                                                                                                                    |
| <b>established</b>                            | Match the RST or ACK bits, not other bits of the TCP flag.                                                                                                                                                                                             |
| <i>text</i>                                   | Note                                                                                                                                                                                                                                                   |
