**redistribute isis** [ *tag* ] **level-1 into level-2** [ **route-map** *route-map-name* | **distribute-list** *access-list-name* ]

**no redistribute isis** [ *tag* ] **level-1 into level-2** [ **route-map** *route-map-name* | **distribute-list** *access-list-name* ]

| Parameter Description | Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>tag</i>                                     | Name of the IS-IS instance.                                                                                                                                                                                                                                                                                                                                                                                          |
|                       | <b>route-map</b> <i>route-map-name</i>         | Sets the route map during the route redistribution, which is used to filter the redistributed route and set attributions of this route.<br>Name of the <i>route-map-name</i> shall not be over 32 characters.<br>No <b>route-map</b> is configured by default.                                                                                                                                                       |
|                       | <b>distribute-list</b> <i>access-list-name</i> | Uses the <b>distribute-list</b> to filter the redistributed routes.<br>Access-list-name is the prefix list associated, it can be the standard, extended or naming prefix list. The format is shown as below:<br>{<1-99>   <100-199>   <1300-1999>   <2000-2699>   <i>acl-name</i> }<br>In the IS-IS <b>address-family ipv6</b> mode, you can use only the naming prefix list with the format being <i>acl-name</i> . |

**Defaults** If the IS-IS Level-2 instance exists, all IS-IS Level-1 routes are by default redistributed into the IS-IS Level-2 instance.

**Command Mode** IS-IS routing process configuration mode or IS-IS **address-family ipv6** mode.

**Usage Guide** Use the **route-map** or **distribute-list** to filter the Level-1 route of the specified instance to be redistributed. Only the route that meets the condition can be redistributed into the Level-1 of current instance.

 You can only choose one of the two parameters **route-map** and **distribute-list**.

Configure the **no distribute isis** [ *tag* ] **level-2 into level-1** to disable the specified instance redistribution. If the **no redistribute** is followed by any other parameters, it means that this parameter is restored to the default setting instead of disabling the specified instance redistribution.

For example: "**no redistribute isis tag1 level-1 into level-2**" will disable the isis tag1 redistribution, while "**no redistribute isis tag1 level-1 into level-2 route-map aa**" will disable route-map aa filtering during redistribution instead of disabling the isis tag1 redistribution.

**Configuration Examples**

```
Ruijie(config)# router isis aa
Ruijie(config-router)# redistribute isis bb level-1 into level-2
```

**Platform** N/A

**Description**

## 4.61 redistribute isis level-2 into level-1

Use this command to redistribute the Level-2 reachable routing information of the IS-IS instance into the Level-1 of current instance. Use the **no** form of this command to remove the redistribution.

**redistribute isis** [ *tag* ] **level-2 into level-1** [ **route-map** *route-map-name* | **distribute-list** *access-list-name* | **prefix** *ip-address net-mask* ]

**no redistribute isis** [ *tag* ] **level-2 into level-1** [ **route-map** *route-map-name* | **distribute-list** *access-list-name* | **prefix** *ip-address net-mask* ]

**Parameter Description**

**Platform** N/A

**Description**

## 4.62 router isis

Use this command to create the IS-IS instance. Use the **no** form of this command to delete this instance.

**router isis** [ *tag* ]

**no router isis** [ *tag* ]

**Parameter  
Description**

| Parameter  | Description   |
|------------|---------------|
| <i>tag</i> | Instance name |

**Defaults** By default, no IS-IS instance is configured.

**Command** Global configuration mode

**Mode**

**Usage Guide** Use this command to initialize the IS-IS instance and enter the IS-IS routing process configuration mode.

The IS-IS instance will not be executed unless one NET address is configured at least.

When enabling the IS-IS routing process with the parameter *tag*, the parameter *tag* will be used as well when disabling the IS-IS routing process.

By default, the CPU protection is enabled on the switch, so that the number of packets corresponding to the destination group addresses of ISIS (AllISSystems, AllL1ISSystems, AllL2ISSystems) is limited when they are sent to the CPU, for example , the default limited value is 400pps. The number of packets received by the switch may be larger than the default value if there are many neighbors or the interval for sending Hello packets is short, resulting in continual vibration of the adjacent relation. In this case, you need to raise the limit of IS-IS packets using the global commands **cpu-protect type**

**isis-is pps, cpu-protect type isis-l1is pps** and **cpu-protect type isis-l2is pps**.

```

Configuration  Ruijie# configure terminal
Examples       Ruijie(config)# router isis
    
```

| <b>Defaults</b>      | The function of instructing a neighbor not to use the local IS-IS node as a transit device for forwarding data is disabled by default.                                                                                                                                                                                                                                                                       |
| <b>Command Mode</b>  | IS-IS routing process configuration mode                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default Level</b> | 14                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Usage Guide</b>   | <p>This command forces a IS-IS node to set the OVERLOAD bit in non-virtual LSP packets, to instruct IS-IS neighbors not to use the local node as a transit device.</p> <p>If the <b>on-startup</b> keyword is carried, the device automatically enters the OVERLOAD state after restart. If the <b>on-startup</b> keyword is not carried, the device immediately enters the OVERLOAD state upon restart.</p> |

---

 The **on-startup** keyword takes effect for only one level.

---

The OVERLOAD bit is mainly used in the following cases:

- Device overload

The overload of the local IS-IS node, for example, memory insufficiency or CPU full load, may cause incomplete routes in the local routing table or no resource for data forwarding. You can set the OVERLOAD bit in LSP packets to instruct neighbors not to use the local node as a transit device.

In this case, the **on-startup** keyword is not carried in the configuration. The OVERLOAD bit is manually set or cancelled. You must manually cancel this command after the local IS-IS node restores to the normal state. Otherwise, the local IS-IS node is always in the OVERLOAD state

- Instantaneous black hole

In the scenario described in RFC3277, the IS-IS converges faster than BGP does. After an IS-IS node restarts, the route fails instantaneously, that is, instantaneous black hole occurs. You can set the OVERLOAD bit in LSP packets to instruct neighbors not to use the local node as a transit device till the specified timer expires.

In this case, the configuration must carry the **on-startup** field. The OVERLOAD bit is automatically set or cancelled by the IS-IS node based on the configuration.

After the **on-startup** field is selected, the IS-IS node automatically enters the instantaneous black hole state after restart. After a new neighbor relationship is established, the IS-IS node immediately sends the LSP packet that carries the OVERLOAD bit to notify the neighbor that the local device enters the instantaneous black hole state (or OVERLOAD state) and that the local node cannot be used as a transit device.

When the specified timer expires, the IS-IS node immediately sends the LSP packet without the OVERLOAD bit to notify the neighbor that the local device is no longer in the instantaneous state (or OVERLOAD state) and can be used as a transit device.

The timer time needs to be set based on the number of routes in the network. If there are many routes, set it to a large value; if there are a few routes, set it to a small value.

- The local IS-IS node is not intended to be used for forwarding real data

If the local IS-IS node needs to be connected to the production network for testing or other function requirements and it is not intended to be used for forwarding real data in the network, you can set the OVERLOAD bit in LSP packets to instruct neighbors not to use the local device as a transit device.

In this case, the **on-startup** field is not carried in the configuration and the OVERLOAD bit is manually set or cancelled.

You can configure **suppress** as required to restrict the routing information carried in LSP packets in the OVERLOAD state, for example, suppress internal routes and external routes and advertise only local direct routes.

**Configuration Examples** The following example sets an IS-IS node to immediately enter the instantaneous black hole state after restart till the specified timer expires (set the specified waiting time to 300 seconds) and advertises only local direct routes to neighbors.

```
Ruijie(config)# router isis
Ruijie(config-router)#set-overload-bit on-startup 300 suppress interlevel
external
```

The following example connects the local IS-IS node to the production network as a test device and set its not to forward real data of the production network, to avoid impact on production.

```
Ruijie(config)# router isis
Ruijie(config-router)#set-overload-bit suppress interlevel external
```

## 4.64 spf-interval

Use this command to set the minimal interval for the SPF calculation. Use the **no** form of this command to restore the default minimal interval.

**spf-interval** [ **level-1** | **level-2** ] *maximum-interval* [*initial-interval* *hold-interval*]

**no spf-interval** [ **level-1** | **level-2** ]

| Parameter Description | Parameter               | Description                                                                                                                                                                              |
|-----------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>level-1</b>          | Applies the configuration only to Level-1.                                                                                                                                               |
|                       | <b>level-2</b>          | Applies the configuration only to Level-2.                                                                                                                                               |
|                       | <i>maximum-interval</i> | Indicates the maximum interval for performing two consecutive SPF calculations. The value range is <b>1</b> to <b>120</b> (in seconds). The default value is <b>10</b> .                 |
|                       | <i>initial-interval</i> | Indicates the waiting time for performing the SPF calculation for the first time. The value range is <b>0</b> to <b>60000</b> (in milliseconds). The default value is <b>50</b> .        |
|                       | <i>hold-interval</i>    | Indicates the minimum interval for performing the SPF calculation for the second time. The value range is <b>10</b> to <b>60000</b> (in milliseconds). The default value is <b>200</b> . |

**Defaults** By default, this command is not configured.  
 The default SPF interval is 10 seconds, which takes effect at both Level-1 and Level-2.

**Command Mode** IS-IS routing process configuration mode

**Usage Guide** Increasing the maximum interval for performing SPF calculations can avoid frequent SPF calculations and waste of CPU resources. However, a larger minimum interval also leads to slower responses to route changes.

The waiting time for performing the SPF calculation for the first time is the initial interval. If the network becomes unstable, the SPF calculation interval is less than the maximum interval, and the interval for performing the SPF calculation for the second time becomes the hold interval. A corresponding penalty is added to this interval: The next interval for the SPF calculation doubles the previous interval for the same SPF calculation, until the SPF calculation interval reaches the maximum interval. Subsequent SPF calculations are performed at the maximum interval. When the network becomes stable, the interval for performing the SPF calculation becomes greater than the maximum interval, and the waiting time for performing the SPF calculation is restored to the initial interval.

Link changes have high requirements for convergence. The initial interval can be set to a small value. The preceding parameters can also be adjusted to larger values to reduce CPU consumption.

The value of **initial-interval** cannot be greater than that of **maximum-interval**. Otherwise, the value of **initial-interval** will be used as the value of **maximum-interval**.

The value of **hold-interval** cannot be greater than that of **maximum-interval**. Otherwise, the value of **hold-interval** will be used as the value of **maximum-interval**.

The value of **initial-interval** cannot be greater than that of **hold-interval**. Otherwise, the value of **initial-interval** will be used as the value of **hold-interval**.

**Configuration Examples** The following example sets the maximum interval for generating two duplicate SPF packets to 5 seconds, the interval for generating a duplicate SPF packet for the first time to 100 ms, and the interval for generating a duplicate SPF packet for the second time to 200 ms.

```
Ruijie(config)# router isis
Ruijie(config-router)# spf-interval 5 100 200
```

The following example sets the maximum interval for generating two duplicate SPF packets to 10 seconds.

```
Ruijie(config)# router isis
Ruijie(config-router)# spf-interval 10
```

## 4.65 summary-address

Use this command to configure the IPv4 aggregation route. Use the **no** form of this command to delete the aggregation route.

**summary-address** *ip-address net-mask* [ **level-1** | **level-2** | **level-1-2** ] [*metric number*]

**no summary-address** *ip-address net-mask*

| Parameter Description | Parameter         | Description                                                                            |
|-----------------------|-------------------|----------------------------------------------------------------------------------------|
|                       | <i>ip-address</i> | Indicates the IP address of the summary route.                                         |
|                       | <i>net-mask</i>   | Indicates the subnet mask of the summary route.                                        |
|                       | <b>level-1</b>    | Applies the setting only to Level-1.                                                   |
|                       | <b>level-2</b>    | Applies the setting only to Level-2. By default, the setting takes effect for Level-2. |
|                       | <b>level-1-2</b>  | Applies the setting to Level-1 and Level-2.                                            |
|                       | <i>number</i>     | Indicates the metric of the summary route.                                             |

**Defaults** By default, no aggregation route is configured.

**Command Mode** IS-IS routing process configuration mode

**Usage Guide** With the aggregation route configured, if there is any reachable address or reachable network segment route in the aggregation route, it will publish the aggregation route instead of the detailed route.

**Configuration** Ruijie(config)# **router isis**

**Examples** Ruijie(config-router)# **summary-address** 10.10.0.0/24 **level-1-2**

## 4.66 summary-prefix

Use this command to configure the IPv6 aggregation route. Use the **no** form of this command to delete the aggregation route.

**summary-prefix** *ipv6-prefix/prefix-length* [ **level-1** | **level-2** | **level-1-2** ]

**no summary-address** *ipv6-prefix/prefix-length*

| Parameter Description | Parameter                          | Description                                                                              |
|-----------------------|------------------------------------|------------------------------------------------------------------------------------------|
|                       | <i>ipv6-prefix / prefix-length</i> | Aggregation network address and the IP prefix length of the aggregation network address. |
|                       | <b>level-1</b>                     | Applies to the Level-1 only.                                                             |
|                       | <b>level-2</b>                     | Applies to the Level-2 only.                                                             |
|                       | <b>level-1-2</b>                   | Applies to both Level-1 and Level-2.                                                     |

**Defaults** By default, no aggregation route is configured.

**Command** Address-family ipv6 mode

**Mode**

**Usage Guide** With the aggregation route configured, if there is any reachable address or reachable network segment route in the aggregation route, it will publish the aggregation route instead of the detailed route.

**Configuration** Ruijie(config)# **router isis**

**Examples** Ruijie(config-router)# **address-family ipv6**

Ruijie (config-router-af)# **summary-prefix 1000::/96 level-1-2**

**Description**

## 4.67 two-way-maintain

Use this command to enable the IS-IS two-way maintenance function.

**two-way-maintain**

Use the **no** form of this command to disable the IS-IS two-way maintenance function.

**no two-way-maintain**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The IS-IS two-way maintenance function is enabled by default.

**Command** IS-IS routing process configuration mode

**Mode****Default Level** 14

**Usage Guide** In a large-scale network, a large number of packets are sent and received, which occupies lots of CPU and memory resources, causing the delay or discarding of some IS-IS packets. If the time required for processing hello packets exceeds the neighbor relationship maintenance duration, the corresponding neighbor relationship times out and is removed. When the two-way maintenance function is enabled, if a large number of packets exist on the network, the LSP packets, CSNP packets, and PSNP packets from a neighbor in addition to hello packets can also be used to maintain the two-way relationship with the neighbor, preventing the neighbor failure caused by delay or discarding of hello packets.

**Configuration** The following example disables the IS-IS two-way maintenance function.

**Examples**

```
Ruijie(config)# router isis 1
Ruijie(config-router)# no two-way-maintain
```

## 4.68 virtual-system

Use this command to configure an additional system ID for fragment extension. Use the **no** form of this command to remove the additional system ID.

**virtual-system** *system-id*

**no virtual-system** *system-id*

**Parameter Description**

| Parameter        | Description                                  |
|------------------|----------------------------------------------|
| <i>system-id</i> | Additional system ID. The length is 6 bytes. |

**Defaults** No additional system ID is configured by default.

**Command** IS-IS routing process configuration mode

**Mode**

**Usage Guide** Use this command to configure an additional system ID for LSP fragment extension. The system must be enabled with fragment extension mode and configured with the additional system ID to enable LSP fragment extension.

**Configuration** The following example configures an additional system ID for fragment extension.

**Examples**

```
Ruijie(config)# router isis
Ruijie(config-router)# virtual-system 0000.0000.0034
```

**Description****4.69 vrf**

Use this command to bind the IS-IS process with a VRF instance. Use the **no** form of this command to unbind the IS-IS process from the VRF instance.

**vrf** *vrf-name*

**no vrf** *vrf-name*

**Parameter Description**

| Parameter       | Description                                             |
|-----------------|---------------------------------------------------------|
| <i>vrf-name</i> | VRF instance name. The VRF instance must be configured. |

**Defaults**

No IS-IS process is bound with the VRF instance.

**Command**

IS-IS routing process configuration mode

**Mode****Usage Guide**

Before you configure this command, the specified VRF instance must be configured. If you want to build the IS-IS v6 neighbor, the multi-protocol VRF and IPv6 protocol must be enabled.

The following restrictions are for binding IS-IS process with VRF instance:

1. The IS-IS process in the same non-default VRF instance must be configured with a different system ID. The IS-IS process in the different VRF instance can be configured with the same system ID.
2. An IS-IS process can be bound with only one VRF instance. A VRF instance can be bound with multiple IS-IS processes.
3. If a VRF instance bound with an IS-IS changes, the IS-IS enabled interfaces which are bound with the VRF instance and the redistribute configuration in IS-IS routing process configuration mode will be removed.

**Configuration**

The following example binds an IS-IS process with a VRF instance.

**Examples**

```
Ruijie(config)#vrf definition vrf_1
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#exit-address-family

Ruijie(config)# router isis
Ruijie(config-router)# vrf vrf_1
```

### 4.75 show isis hostname

Use this command to display the mapping relation between the router name and system ID.

**show isis [ tag ] hostname**

| Parameter Description | Parameter | Description                   |
|-----------------------|-----------|-------------------------------|
|                       | tag       | Specifies the IS-IS instance. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ global configuration mode/ interface configuration mode

**Usage Guide** N/A

**Configuration**

```

Ruijie# show isis hostname

  System ID      Dynamic Hostname      Area (null)
* 5555.5555.5555 Ruijie
  1111.1111.1111 R1

  System ID      Dynamic Hostname      Area 1
* 4444.4444.4444 Ruijie
  2222.2222.2222 R2
    
```

### 4.76 show isis ipv6 topology

Use this command to display information about the IPv6 unicast topology to which an IS-IS router is connected.

**show isis [ tag ] ipv6 topology [ I1 | I2 | level-1 | level-2 ]**

---

| Parameter Description | Parameter      | Description                            |
|-----------------------|----------------|----------------------------------------|
|                       | <i>tag</i>     | IS-IS instance                         |
|                       | <b>I1</b>      | Topology of a specified Level-1 router |
|                       | <b>level-1</b> | Topology of a specified Level-1 router |
|                       | <b>I2</b>      | Topology of a specified Level-2 router |
|                       | <b>level-2</b> | Topology of a specified Level-2 router |

**Command Mode** Privileged EXEC mode, global configuration mode, and interface configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Examples** The following example displays the IPv6 unicast topology information.

```
Ruijie#show isis ipv6 topology
Area (null):
IS-IS paths to level-1 routers
System Id   Metric   Next-Hop   SNPA           Interface
r1          10      r1         00d0.f822.33ad GigabitEthernet 0/0
Ruijie      --
IS-IS paths to level-2 routers
System Id   Metric   Next-Hop   SNPA           Interface
r1          10      r1         00d0.f822.33ad GigabitEthernet 0/0
Ruijie      --
```

Field description:

| Field     | Description    |
|-----------|----------------|
| Area      | Instance tag   |
| System Id | System ID      |
| Metric    | Metric value   |
| Next-Hop  | Next hop       |

| Interface | Interface name |

## 4.77 show isis interface

Use this command to display the information about IS-IS interface.

**show isis** [ *tag* ] **interface** [ *interface-type interface-number* ] [ *counter* ]

| Parameter Description | Parameter  | Description                        |
|-----------------------|------------|------------------------------------|
|                       | <i>tag</i> | Specifies the IS-IS instance name. |

|                                                  |                               |
|--------------------------------------------------|-------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | Specifies the Interface name. |
|--------------------------------------------------|-------------------------------|

**Command** Privileged EXEC mode, global configuration mode or interface configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example displays the IS-IS interface.

**Examples**

```
Ruijie# show isis interface
Area (null):
VLAN 1 is up, line protocol is up
  Routing Protocol: IS-IS ((null))
    Network Type: Broadcast
    Circuit Type: level-1-2
    Local circuit ID: 0x01
    Extended Local circuit ID: 0x00000001
    Local SNPA: 00d0.f822.33ab
    IP interface address:
      1.0.0.1/24
    Level-1 Metric: 10/10, Priority: 64, Circuit ID: r1.01

    Level-1 Timer intervals configured, Hello: 10s, Lsp: 33ms, Psnp: 2s, Csnp:10s,
    Retransmit:5s

    Level-1 LSPs in queue: 0

    Level-1 LSPs flood: 5

    Number of active level-1 adjacencies: 1
    Level-2 Metric: 10/10, Priority: 64, Circuit ID: r1.01

    Level-2 Timer intervals configured, Hello: 10s, Lsp: 33ms, Psnp: 2s, Csnp:10s,
    Retransmit:5s

    Level-2 LSPs in queue: 0

    Level-2 LSPs flood: 5

    Number of active level-2 adjacencies: 1
    Next IS-IS LAN Level-1 Hello in 5 seconds
    Next IS-IS LAN Level-2 Hello in 5 seconds
    BFD Enabled (Anti-congestion)
    Eligible to backup traffic
```

The following example displays the statistics of the IS-IS interface.

```
Ruijie# show isis interface counter
```

```

Area (null):
GigabitEthernet 1/1/0:

## 4.78 show isis mesh-groups

Use this command to display the mesh-group configurations on each interface.

**show isis** [ *tag* ] **mesh-groups**

| Parameter Description | Parameter  | Description                   |
|-----------------------|------------|-------------------------------|
|                       | <i>tag</i> | Specifies the IS-IS instance. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode, global configuration mode or interface configuration mode.

N/A

**Usage Guide**

**Configuration** The following example displays the mesh groups.

**Examples**

```
Ruijie# show isis mesh-groups
Mesh group (blocked)
FastEthernet 1/1
Mesh group 1 :
FastEthernet 1/0
```

## 4.79 show isis neighbors

Use this command to display the IS-IS neighbors..

**show isis** [ *tag* ] **neighbors** [ *detail* ]

| Parameter Description | Parameter     | Description                                          |
|-----------------------|---------------|------------------------------------------------------|
|                       | <i>tag</i>    | Displays the IS-IS instance.                         |
|                       | <i>detail</i> | Displays the detailed information of all interfaces. |

**Defaults** N/A

**Command** Privileged EXEC mode, global configuration mode or interface configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example displays details of IS-IS neighbors.

**Examples**

```
Ruijie# show isis neighbors detail

Area (null):
System Id  Type  IP Address  State  Holdtime  Circuit  Interface
r1         L1   1.0.0.2    Up     9         r1.01   GigabitEthernet 0/0
           L2   1.0.0.2    Up     9         r1.01   GigabitEthernet 0/0

Adjacency ID: 1
Uptime: 00:06:25
Area Address(es): 49.1111

### 4.80 show isis virtual-neighbors

Use this command to display the virtual system neighbor information of an IS-IS system.

**show isis [ tag ] virtual-neighbors**

**Parameter Description**

| Parameter  | Description     |
|------------|-----------------|
| <i>tag</i> | IS-IS instance. |

**Command Mode** Privileged EXEC mode, global configuration mode, and interface configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Examples**

```
Ruijie# show isis virtual-neighbors

Area (null):
Virtual System Id      Type      State
1111.1111.1111        L1        DOWN
                      L2        UP
2222.2222.2222        L1        DOWN
                      L2        UP
```

Field description:

| Field             | Description                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------|
| Area              | Instance tag                                                                                  |
| Virtual System Id | Virtual system ID                                                                             |
| Type              | Neighbor type                                                                                 |
| State             | Neighbor status. <b>UP</b> indicates the level at which the extended LSP fragment is created. |

## 4.81 show isis protocol

Use this command to display relevant protocol information about an IS-IS system.

**show isis [ tag ] protocol**

**Parameter Description**

| Parameter | Description     |
|-----------|-----------------|
| tag       | IS-IS instance. |

**Command Mode** Privileged EXEC mode, global configuration mode, and interface configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Examples** The following example displays relevant protocol information about an IS-IS system.

```
Ruijie# show isis protocol
IS-IS Router: (null)
  Binding VRF: vrf
  Mib-Binding: off
  System ID: 0000.0000.0036 IS-type: level-1-2
  Virtual System ID:
    1111.1111.1111, 2222.2222.2222
  Manual area address(es):
```

## 4.82 show isis topology

Use this command to display the topology of the IS-IS router connection.

**show isis [ tag ] topology [WORD | all] [ I1 | I2 | level-1 | level-2 ]**

Parameter  
Description

| Parameter | Description                   |
|-----------|-------------------------------|
| tag       | Specifies the IS-IS instance. |

|                       |                                                                                  |
|-----------------------|----------------------------------------------------------------------------------|
| <i>WORD</i>           | System ID or host name.                                                          |
| <b>self-originate</b> | Displays the topology of the device.                                             |
| <b>all</b>            | Displays the topology whose root node is the local device or the IS-IS neighbor. |
| <b>l1</b>             | Specifies the topology of Level-1.                                               |
| <b>level-1</b>        | Specifies the topology of Level-1.                                               |
| <b>l2</b>             | Specifies the topology of Level-2.                                               |
| <b>level-2</b>        | Specifies the topology of Level-2.                                               |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/ global configuration mode/ interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays all IS-IS neighbors:

```

Examples Ruijie#show isis topology
Area (null):
IS-IS paths to level-1 routers
System Id    Metric  Next-Hop  SNPA          Interface
r1           10     r1        00d0.f822.33ad GigabitEthernet 0/0
Ruijie      --
IS-IS paths to level-2 routers
System Id    Metric  Next-Hop  SNPA          Interface
r1           10     r1        00d0.f822.33ad GigabitEthernet 0/0
Ruijie      --
    
```

## 5 BGP4 Commands

### 5.1 address-family ipv4

Use this command to enter IPv4 address family configuration mode to configure BGP configuration mode. Use the **no** or **default** form of this command to exit BGP address configuration mode.

**address-family ipv4 [unicast|multicast]**

**no address-family ipv4 [unicast|multicast]**

**default address-family ipv4 [ unicast ]**

| Parameter   | Parameter      | Description                                    |
|-------------|----------------|------------------------------------------------|
| Description | <b>unicast</b> | Optional, detailed IPv4 unicast address prefix |

**Defaults** The configuration mode is unicast address prefix by default.

#### Command

**Mode** BGP configuration mode

**Usage** In BGP address configuration mode, use the standard IPv4 address for the configuration.

**Guide** To return to BGP configuration mode, run the command **exit-address-family**.

#### Configuration

The following example enters the IPv4 address family configuration mode.

#### Examples

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# address-family ipv4
```

| Related  | Command                    | Description     |
|----------|----------------------------|-----------------|
| Commands | <b>exit-address-family</b> | Exits the mode. |

#### Platform

**Description** None

### 5.2 address-family ipv4 vrf

Use this command to enter the IPv4 VRF address family configuration mode to configure BGP and enable the exchange of route information of a VRF. Use the **no** or **default** form of this command to restore the default setting.

**address-family ipv4 vrf vrf-name**

**no address-family ipv4 vrf vrf-name**

**default address-family ipv4 vrf vrf-name**

| Parameter   | Parameter       | Description |
|-------------|-----------------|-------------|
| Description | <i>vrf-name</i> | VRF name    |

**Defaults** No vrf is defined by default.

**Command**

**Mode** BGP configuration mode

You can execute this command to configure or exit the exchange of route information between PEs and CEs.

**Usage**

To return to BGP configuration mode, run the **exit-address-family** command.

**Guide**

If IPv4 VRF and IPv6 VRF address family modes of the same VRF are activated at the same time, and the same neighbor is activated in two address family modes, the neighbor's global commands will be displayed in both address family modes at the same time, while its address family commands will be displayed only under respective address family modes.

**Configuration**

The following example enters the IPv4 VRF address family configuration mode.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# address-family ipv4 vrf vpn1
```

**Related**

**Commands**

| Command                    | Description                   |
|----------------------------|-------------------------------|
| <b>exit-address-family</b> | Exits the configuration mode. |

**Platform**

**Description** N/A

## 5.3 address-family ipv6

Use this command to enter IPv6 address family configuration mode and enable the exchange of IPv6 route information. Use the **no** or **default** form of this command to restore the default setting. Use the **exit-address-family** command to exit BGP address-family configuration mode.

**address-family ipv6 [unicast]**

**no address-family ipv6 [unicast]**

**default address-family ipv6 [ unicast ]**

| Parameter   | Parameter      | Description                                                      |
|-------------|----------------|------------------------------------------------------------------|
| Description | <b>unicast</b> | Optional, enters IPv6 unicast address-family configuration mode. |

**Defaults** The configuration mode is unicast address prefix by default.

**Command**

**Mode** BGP configuration mode or BGP Scope configuration mode

**Usage** You can use this command not only to enter IPv6 address-family configuration mode of the BGP to configure the IPv6 neighbors, but also activate neighbors in IPv6 address-family configuration mode after configuring IPv6 neighbors in BGP configuration mode.

**Guide** The **exit-address-family** command is used to return to BGP configuration mode.

**Configuration Examples**

The following example enters the IPv6 address family configuration mode.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# address-family ipv6
```

**Related Commands**

| Command                    | Description     |
|----------------------------|-----------------|
| <b>exit-address-family</b> | Exits the mode. |

**Platform**

**Description** None

## 5.4 address-family ipv6 vrf

Use this command to enter BGP configuration mode, enable the IPv6 route information exchange function under a vrf. Use **no** or **default** form of this command to restore the default setting. Use the **exit-address-family** command to exit BGP address configuration mode.

**address-family ipv6 vrf** *vrf-name*

**no address-family ipv6 vrf** *vrf-name*

**default address-family ipv6 vrf** *vrf-name*

**Parameter Description**

| Parameter       | Description |
|-----------------|-------------|
| <i>vrf-name</i> | VRF name    |

**Defaults** No vrf address family is defined by default.

**Command Mode** BGP configuration mode

**Usage Guide** You can use this command to start configuring (or quit) the exchange of BGP route information between PE or MCE device and CE.

You can use the exit-address-family command to return to BGP configuration mode.

 If ipv4 vrf and ipv6 vrf address family modes of the same vrf are activated at the same time, and same neighbor is activated in two address family modes, the neighbor's global commands will be displayed in both the address family modes at the same time, while its address family commands will only be displayed under respective address family mode.

**Configuration Examples** The following example enters the IPv6 VRF address family configuration mode.

```
Ruijie(config)# router bgp 65000
```

```
Ruijie(config-router)# address-family ipv6 vrf vpn1
```

| Configuration Examples | Command | Description                |
|------------------------|---------|----------------------------|
|                        |         | <b>exit-address-family</b> |

Platform N/A

Description

## 5.5 address-family l2vpn

Use this command to enter the L2VPN address family configuration mode and enable the exchange of L2VPN route information between BGP neighbors. Use the **no** or **default** form of this command to restore the default settings.

**address-family l2vpn {evpn}**

**no address-family l2vpn {evpn }**

**default address-family l2vpn {evpn }**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | <b>evpn</b> |

Defaults No L2VPN address family is defined by default.

Command

Mode BGP configuration mode / BGP scope global configuration mode

Usage

Guide Use the **exit-address-family** command to exit the L2VPN address family configuration mode.

Configuration Examples The following example enters the L2VPN VPLS address family configuration mode.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# address-family l2vpn vpls
```

## 5.6 advertise ipv4 unicast

Use this command to configure IPv4 VRF re-distribution. Use the **no** form of this command to disable the IPv4 VRF re-distribution. Use the **default** form of this command to restore the default settings.

**advertise ipv4 unicast**

**no advertise ipv4 unicast**

**default advertise ipv4 unicast**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** The IPv4 VRF re-distribution function is disabled by default.

### Command

**Mode** BGP L2VPN EVPN address family mode.

Limitations on re-distribution of IPv4 unicast routes into BGP:

1. The re-distribution of IPv4 unicast routes into BGP function can only take effect in BGP L2VPN EVPN address family mode.
2. Only after the VXLAN module has advertised the L3 virtual MAC address, the IPv4 unicast routes can be re-distributed.
3. Only after the route-target import attribute of EVI instance matches the route-target attribute of VRF, the IPv4 unicast routes can be re-distributed.
4. The non-VRF IPv4 unicast routes cannot be re-distributed.

### Usage

### Guide

The following example configures the re-distribution of IPv4 unicast routes into BGP.

### Configuration

### Examples

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# address-family l2vpn evpn
Ruijie(config-router-af)# advertise ipv4 unicast
```

| Related Commands | Command | Description |

## 5.7 advertise ipv6 unicast

Use this command to configure IPv4 VRF re-distribution. Use the **no** form of this command to disable the IPv4 VRF re-distribution. Use the **default** form of this command to restore the default settings.

**advertise ipv6 unicast**

**no advertise ipv6 unicast**

**default advertise ipv6 unicast**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** The IPv6 VRF re-distribution function is disabled by default.

**Command**

**Mode** BGP L2VPN EVPN address family mode.

Limitations on re-distribution of IPv6 unicast routes into BGP:

1. The re-distribution of IPv6 unicast routes into BGP function can only take effect in BGP L2VPN EVPN address family mode.
2. Only after the VXLAN module has advertised the L3 virtual MAC address, the IPv6 unicast routes can be re-distributed.
3. Only after the route-target import attribute of EVI instance matches the route-target attribute of VRF, the IPv6 unicast routes can be re-distributed.
4. The non-VRF IPv6 unicast routes cannot be re-distributed.

**Usage**

**Guide**

The following example configures the re-distribution of IPv6 unicast routes into BGP.

**Configuration**

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# address-family l2vpn evpn
Ruijie(config-router-af)# advertise ipv6 unicast
```

## 5.8 aggregate-address (IPv4)

Use this command to set the aggregate IPv4 route. Use the **no** or **default** form of this command to restore the default setting.

**aggregate-address** *ip-address mask* [**as-set**] [**summary-only**] [**attribute-map** *map-tag* ]

**no aggregate-address** *ip-address mask*

**default aggregate-address** *ip-address mask*

| Parameter   | Parameter         | Description                       |
|-------------|-------------------|-----------------------------------|
| Description | <i>ip address</i> | IP address of the aggregate route |

|                      |                                                                           |
|----------------------|---------------------------------------------------------------------------|
| <i>mask</i>          | Mask of the aggregate route                                               |
| <b>as-set</b>        | Keeps the AS path information of the path in the aggregate address range. |
| <b>summary-only</b>  | Advertises only the aggregate route.                                      |
| <b>attribute-map</b> | Configures the routing policy to control the route attribute.             |
| <i>map-tag</i>       | Route map name. Up to 32 characters is allowed.                           |

**Defaults** The address aggregation is not configured by default.

**Command Mode** BGP configuration mode, IPv4 address family configuration mode, or IPv4 VRF address family configuration mode

**Usage Guide** The BGP-enabled device will advertise all path information both before and after aggregation by default. Use the **aggregate-address summary-only** command to advertise the aggregate route only.

The following example sets the aggregate IPv4 route.

**Configuration Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# aggregate-address 10.0.0.0
255.0.0.0 as-set
```

| Related Commands | Command           | Description               |
|------------------|-------------------|---------------------------|
|                  | <b>router bgp</b> | Enables the BGP protocol. |

**Platform Description** None

## 5.9 bgp advertise non-transitive extcommunity

Use this command to allow carried non-transitive extcommunity when BGP is notifying EBGp neighbors of a route. Use the **no** or **default** form of this command to restore the default setting.

- bgp advertise non-transitive extcommunity**
- no bgp advertise non-transitive extcommunity**
- default bgp advertise non-transitive extcommunity**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** Non-transitive extcommunity is removed when notifying EBGp neighbors of a route.

**Command Mode** BGP configuration mode / Scope global configuration mode

**Usage Guide** By default, when notifying EBGP neighbors of a route, neighbors will not be notified of extcommunity with the "non-transitive" flag. This configuration can enable the notification of non-transitive extcommunity.

 Non-transitive extcommunity will be carried when notifying alliance EBGP or IBGP neighbors of a route.

**Configuration** The following example allows carried non-transitive extcommunity.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp advertise non-transitive extcommunity
```

| Configuration Examples | Command | Description |
|------------------------|---------|-------------|
|                        |         | router bgp  |

**Platform** N/A

**Description**

## 5.10 bgp always-compare-med

Use this command to compare Multi Exit Discriminator (MED) all the time. Use the **no** or **default** form of this command to restore the default setting.

**bgp always-compare-med**

**no bgp always-compare-med**

**default bgp always-compare-med**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** MED of peer paths from the same AS is compared by default.

**Command**

**Mode** BGP configuration mode / Scope global configuration mode

**Usage Guide**

The MED value is compared for paths of peers from the same AS by default. This command can be used to allow comparing MED values for paths from different ASs. If there are multiple valid paths to the same destination, the one with lower MED value has higher priority.

This command is not recommended unless you are sure that different ASs are using the same IGP and routing method.

**Configuration** The following example compares Multi Exit Discriminator (MED) all the time.

**Examples**

```
Ruijie(config)# router bgp 65000
```

```
Ruijie (config-router) # bgp always-compare-med
```

### Related Commands

|------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>show ip bgp</b>                       | Displays the BGP route entry.                                                                      |
| <b>bgp bestpath med confed</b>           | Compares the MED value of paths of peers from different ASs when selecting the optimal path.       |
| <b>bgp bestpath med missing-as-worst</b> | Sets the priority of the path without MED attribute as the lowest when selecting the optimal path. |
| <b>bgp deterministic-med</b>             | Compares paths of peers from the same AS when selecting the optimal path.                          |

### Platform

**Description** None

## 5.11 bgp asnotation dot

Use this command to modify the displaying mode of the 4-byte AS notation and the matching type of the regular expression as the dot mode (that is, two dotted decimal numbers). Use the **no** or **default** form of this command to restore the default setting.

**bgp asnotation dot**

**no bgp asnotation dot**

**default bgp asnotation dot**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

### Defaults

The 4-byte AS notation is shown in decimal digit, and the regular expression also matches the 4-byte AS notation with decimal digit by default.

### Command

**Mode** BGP configuration mode / Scope global configuration mode

### Usage Guide

Our devices support two modes of representing the 4-byte AS notation. One is decimal digit, and the other one is dot mode which represents the 65536 with 1.0. The decimal format is same as the default format, which represents the 4-byte AS notation with decimal digits. The dot mode displays the 4-byte AS notation in the format of ([two high bytes.] two low bytes). If the [two high bytes.] is zero, it will not be displayed. That is, the AS notation represented as 65536 in decimal is 1.0 in the dot mode. In another example, the AS notation is 65534 represented in decimal, while it is represented as 65534 in the dot mode without the zero in front.

No matter which mode will be adopted to display the 4-byte AS notation, both modes can be used when entering the configuration commands. But the representation and displaying mode of the 4-byte AS notation in the regular expression must be the same. Otherwise, the matching will fail. After executing the **bgp asnotation** command, you must use the clear ip bgp \* to perform the

resetting, so as to re-match the filtering condition of the regular expression.

 The AS notation is represented as 1 to 65535 no matter using decimal or dot mode.

### Configuration Examples

The following example modifies the showing mode of the 4-byte AS notation.

```
Ruijie(config)# router bgp 1.0
Ruijie(config-router)# bgp asnotation dot
```

|----------------------------|---------------------------------------------------|
| <b>show ip bgp summary</b> | Displays the related information of BGP neighbor. |

### Platform

**Description** None

## 5.12 bgp bestpath as-path ignore

Use this command to disregard the length of the AS path. Use the **no** or **default** form of this command to restore the default setting.

**bgp bestpath as-path ignore**

**no bgp bestpath as-path ignore**

**default bgp bestpath as-path ignore**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

### Defaults

The AS path length is considered in choosing the optimal path by default.

### Command Mode

**Mode** BGP configuration mode / Scope global configuration mode

### Usage Guide

BGP will not take the length of the AS path into account when it selects the optimal path as specified in RFC1771. In general, the shorter the length of the AS path, the higher the path priority is. Hence, we take the length of the AS path into account when we select the optimal path. You can determine whether it is necessary to take the length of the AS path into account when you select the optimal path according to the actual condition.

### Configuration Examples

The following example disregard the length of the AS path.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp bestpath as-path ignore
```

### Related Commands

| Command            | Description                   |
|--------------------|-------------------------------|
| <b>show ip bgp</b> | Displays the BGP route entry. |

**Platform**  
**Description**        None

## 5.13 bgp bestpath as-path multipath-relax

Use this command to enable AS path multipath-relax (only comparing the AS path length) for BGP multipathing load. Use the **no** or **default** form of this command to restore the default setting.

**bgp bestpath as-path multipath-relax**  
**no bgp bestpath as-path multipath-relax**  
**default bgp bestpath as-path multipath-relax**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Command Mode**        BGP requires that AS path attributes must be the same when calculating equal-cost multipath (ECMP) by default.

**Defaults**            BGP configuration mode / Scope global configuration mode

**Usage Guide**        BGP compares AS path attributes in a precise way when selecting the optimal path as ECMP by default. Only paths with same AS path attributes can constitute equal-cost paths. As a result, BGP multipathing load balancing cannot be implemented in an application scenario. After AS path multipath-relax is enabled, only the AS path length is compared, allowing the implementation of BGP multipathing load balancing.

**Configuration Examples**        The following example enables AS path multipath-relax for BGP multipathing load.

```
Ruijie(config)# router bgp 65530
Ruijie(config-router)# bgp bestpath as-path multipath-relax
```

**Platform**            None  
**Description**

## 5.14 bgp bestpath compare-confed-aspath

Use this command to compare the AS path length of the confederation from the same external routes when selecting the optimal path, with smaller AS path in the confederation for higher path priority. Use the **no** or **default** form of this command to restore the default setting.

**bgp bestpath compare-confed-aspath**

**no bgp bestpath compare-confed-aspath**

**default bgp bestpath compare-confed-aspath**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** The AS path of the EBGP peer routes inside the same confederation is not compared by default when selecting the optimal path. Instead, the routing method is implemented.

**Command**

**Mode** BGP configuration mode / Scope global configuration mode

**Usage** During the selection of the same routing information from the peer of the internal EBGP By default, the AS path of the confederation is not compared. This command is used to compare the AS path of the confederation.

**Guide**

Note that if a route contain no AS path of the confederation, it is impossible to implement the AS path comparison for that route.

**Configuration Examples**

The following example compares the AS path length of the confederation.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp bestpath compare-confed-aspath
```

**Description** None

## 5.15 bgp bestpath compare-routerid

Use this command to compare the router ID of the same external routes when selecting the optimal path, with smaller router ID for higher path priority. Use the **no** or **default** form of this command to restore the default setting.

**bgp bestpath compare-routerid**

**no bgp bestpath compare-routerid**

**default bgp bestpath compare-routerid**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

| <b>Defaults</b>               | If two paths received from different EBGP peers have the same path, the first one is considered with higher priority by default.                                                                                                                                                                                                    |         |             |                    |                               |                      |                         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-------------|--------------------|-------------------------------|----------------------|-------------------------|
| <b>Command</b>                |                                                                                                                                                                                                                                                                                                                                     |         |             |                    |                               |                      |                         |
| <b>Mode</b>                   | BGP configuration mode / Scope global configuration mode                                                                                                                                                                                                                                                                            |         |             |                    |                               |                      |                         |
| <b>Usage</b>                  | If two paths with identical path attributes are received from different EBGP peers during the selection of the optimal path, we will select the optimal path according to the sequence of receiving the paths by default. You can select the path with smaller Device ID as the optimal path by configuring the following commands. |         |             |                    |                               |                      |                         |
| <b>Guide</b>                  |                                                                                                                                                                                                                                                                                                                                     |         |             |                    |                               |                      |                         |

| <b>Description</b>      |                                                                                                                                                                                                                                          |  |           |             |                         |                                                                    |
| <b>Defaults</b>         | The MED value of the path of the peer inside the AS confederation is not compared by default when selecting the optimal path.                                                                                                            |  |           |             |                         |                                                                    |
| <b>Command</b>          |                                                                                                                                                                                                                                          |  |           |             |                         |                                                                    |
| <b>Mode</b>             | BGP configuration mode / Scope global configuration mode                                                                                                                                                                                 |  |           |             |                         |                                                                    |
| <b>Usage</b>            | The MED attribute of the path is transferred between the ASs inside the confederation. You may set                                                                                                                                       |  |           |             |                         |                                                                    |
| <b>Guide</b>            | always comparing this value.                                                                                                                                                                                                             |  |           |             |                         |                                                                    |

**Configuration Examples** The following example compares the MED value of the path of the internal peer.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp bestpath med confed
```

|                         | Command                                  | Description                                                                                        |
|-------------------------|------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>Related Commands</b> | <b>show ip bgp</b>                       | Displays the BGP route entry.                                                                      |
|                         | <b>bgp always-compare-med</b>            | Compares the MED value of paths of peers from different ASs when selecting the optimal path.       |
|                         | <b>bgp bestpath med missing-as-worst</b> | Sets the priority of the path without MED attribute as the lowest when selecting the optimal path. |
|                         | <b>bgp deterministic-med</b>             | Compares paths of peers from the same AS when selecting the optimal path.                          |

**Platform Description** None

### 5.17 bgp bestpath med missing-as-worst

Use this command to set the priority of the path without MED attribute as the lowest when selecting the optimal path. Use the **no** or **default** form of this command to restore the default setting.

- bgp bestpath med missing-as-worst**
- no bgp bestpath med missing-as-worst**
- default bgp bestpath med missing-as-worst**

|                              | Parameter | Description |
|------------------------------|-----------|-------------|
| <b>Parameter Description</b> | N/A       | N/A         |

**Defaults** If a path without MED attribute is received, the MED value of the path is 0 by default. Such route has the highest priority according to the above-mentioned rule.

**Command Mode** BGP configuration mode / Scope global configuration mode

**Usage Guide** The MED value of a path without MED attribute will be 0 by default. For the smaller the MED value, the higher the priority of the path is, the MED value of this path has the highest priority. This command can be used to figure the path without MED attribute has the lowest priority.

**Configuration Examples** The following example sets the priority of the path without MED attribute as the lowest.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp bestpath medmissing-as-worst
```

| <b>Commands</b> | <b>show ip bgp</b>             | Displays the BGP route entry.                                                                      |
|                 | <b>bgp always-compare-med</b>  | Compares the MED value of paths of peers from different ASs when selecting the optimal path.       |
|                 | <b>bgp bestpath med confed</b> | Sets the priority of the path without MED attribute as the lowest when selecting the optimal path. |
|                 | <b>bgp deterministic-med</b>   | Compares paths of peers from the same AS when selecting the optimal path.                          |

**Platform****Description** None

## 5.18 bgp bestpath multipath-compare-routerid

Use this command to enable the router ID comparison among multiple BGP paths. Load balancing can be implemented only when multiple paths (same router ID) are from the same device. Use the **no** form of this command to disable the router ID comparison among multiple BGP paths. Use the **default** form of this command to restore the default settings.

**bgp bestpath multipath-compare-routerid****no bgp bestpath multipath-compare-routerid****default bgp bestpath multipath-compare-routerid**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The router ID comparison among multiple BGP paths is disabled by default.**Command Mode** BGP configuration mode, BGP Scope Global Configuration Mode**Default Level** 14**Usage Guide** N/A**Configuration Example** The following example enables the router ID comparison among multiple BGP paths.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp bestpath multipath-compare-routerid
```

**Verification** Run the **show running-config** command to display the BGP configuration.

## 5.19 bgp client-to-client reflection

Use this command to enable the route reflection function between clients on the device. Use the **no** or **default** form of this command disables the route reflection function between clients.

**bgp client-to-client reflection**

**no bgp client-to-client reflection**

**default bgp client-to-client reflection**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled without the client for route reflection by default.

### Command

**Mode** BGP configuration mode / Scope global configuration mode

### Usage Guide

In general, it is unnecessary to establish the connection relationship between the clients of the route reflector within the cluster, and the route reflector will reflect the route among clients.

However, if the full connection relationship is established for all clients, the function for the route reflector to reflect the client route can be disabled.

To disable the route reflection function, use the command **no bgp client-to-client reflection**.

### Configuration Examples

The following example shows how to enable the route reflection function between clients on the device.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# no bgp client-to-client
reflection
```

### Related Commands

| Command                                | Description                                                                               |
|----------------------------------------|-------------------------------------------------------------------------------------------|
| <b>bgp cluster-id</b>                  | Configures the cluster ID of the route reflector.                                         |
| <b>neighbor route-reflector-client</b> | Configures the client of the route reflector and configure itself as the route reflector. |

### Platform

**Description** None

## 5.20 bgp cluster-id

Use this command to configure the cluster ID of the route reflector. Use the **no** or **default** form of this command to restore it to the default setting.

**bgp cluster-id** *cluster-id*

**no bgp cluster-id**

**default bgp cluster-id**

| Parameter         | Description                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>cluster-id</i> | Cluster ID of the route reflector, an IP address of up to four bytes or an integer (must be entered in form of IP address) |

**Defaults** The cluster id is the router-id of the route reflector by default.

**Command**

**Mode** BGP configuration mode / Scope global configuration mode

**Usage** In general, one group is only configured with one route reflector. In this case, the Device ID of the route reflector can be used to identify this cluster. To increase the redundancy, you can set more than one route reflector within this cluster. In this case, you must configure the cluster ID, so that one route reflector can identify the route update from other route reflectors of this cluster.

**Configuration** The following example configures the cluster ID of the route reflector.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp cluster-id 10.0.0.1
```

| Command                                | Description                                                                                |
|----------------------------------------|--------------------------------------------------------------------------------------------|
| <b>bgp client-to-client reflection</b> | Configures the route reflection between clients.                                           |
| <b>neighbor route-reflector-client</b> | Configures the client of the route reflector and configures itself as the route reflector. |

## 5.21 bgp confederation identifier

Use this command to configure the AS confederation identifier. Use the **no** or **default** form of this command to restore the default setting.

**bgp confederation identifier** *as-number*

**no bgp confederation identifier**

**default bgp confederation identifier**

| Parameter        | Description                                                                                                                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> | AS confederation identifier in the range from 1 to 65535<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, which is represented as 1 to |

**Parameter**  
**Description**

|  |                          |
|--|--------------------------|
|  | 65535.65535 in dot mode. |
|--|--------------------------|

**Defaults** There is no confederation identifier by default

**Command**

**Mode** BGP configuration mode or BGP Scope Global configuration mode

**Usage Guide**

The confederation is a measure to reduce the connections of IBGP peers within the AS. One AS is divided into several sub ASs and one unified confederation ID (namely, confederation AS number) is set to constitute these sub ASs into a confederation. For the external confederation, the whole confederation is still considered as one AS, and only the confederation AS number is visible for the external network. Within the confederation, the full IBGP peer connection is still established among the BGP Speakers within the sub AS, and the EBGP connection is established among the BGP Speakers within the sub AS. Despite of the EBGP connections established between the BGP speakers in an AS, the next-hop, MED and local priority information remains unchanged in exchanging the information.

**Configuration Examples** The following example configures the AS confederation identifier.

```
Ruijie(config-router)# bgp confederation identifier 65000
```

**Related Commands**

## 5.22 bgp confederation peers

Use this command to configure member ASs of the AS confederation. Use the **no** or **default** form of this command to restore the default setting.

**bgp confederation peers** *as-number* [...*as-number*]

**no bgp confederation peers** *as-number* [...*as-number*]

**default bgp confederation peers** [ *as-number* [...*as-number*] ]

**Parameter Description**

| Parameter        | Description                                                                                                                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> | Member ASs in the confederation range from 1 to 65535.<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |

**Defaults** There is no confederation member by default.

**Command**

**Mode** BGP configuration mode or BGP Scope Global configuration mode

**Usage Guide**

The confederation is a measure to reduce the connections of BGP peers within the AS. One AS is divided into several sub ASs and one unified confederation ID (namely, confederation AS number) is set to constitute these sub ASs into a confederation. The whole external confederation is still considered as one AS, and only the confederation AS number is visible for the external network. Within the confederation, the full IBGP peer connection is still established among the BGP Speakers within the sub AS, and the EBGP connection is established among the BGP Speakers within the sub AS. Despite of the EBGP connections established between the BGP speakers in an AS, the next-hop, MED and local priority information remains unchanged in exchanging the information.

This command is used to specify the member AS of a confederation.

 This command can configure up to 25 members of a confederation at one time. For more members, enter them for several times.

**Configuration**

The following example configures member ASs of the AS confederation.

**Examples**

```
Ruijie(config-router)# bgp confederation peers 65000 65100
```

**Related Commands**

| Command                             | Description                              |

## 5.23 bgp dampening

Use this command to enable the routing attenuation and set the attenuation parameters in the address-family or routing configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**bgp dampening** [*half-life* [*reusing suppressing duration*] | **route-map** *name*]

**no bgp dampening**

**default bgp dampening**

**Parameter Description**

| Parameter          | Description                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>half-life</i>   | Half-life period, ranging from 1 to 45 minutes                                                                     |
| <i>reusing</i>     | When the penalty value reaches this value, the routing suppression is cancelled. The value ranges from 1 to 10000. |
| <i>suppressing</i> | When the penalty value reaches this value, routing is suspended. The value ranges from 1 to 20000.                 |
| <i>duration</i>    | Maximum time for routing suppression, ranging from 1 to 255 minutes                                                |

|             |                                                                                             |
|-------------|---------------------------------------------------------------------------------------------|
| <i>name</i> | Route-map name, apply the routing attenuation to the specified route through the route-map. |
|-------------|---------------------------------------------------------------------------------------------|

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4 unicast address-family configuration mode, BGP IPv4 VRF address-family configuration mode, BGP IPv6 unicast address-family configuration mode, BGP IPv6 VRF address-family configuration mode, BGP L2VPN EVPN address-family configuration mode and BGP Scope configuration mode

The **bgp dampening** command is used to suppress unstable EBGP routes and does not take effect to IBGP routes.

The BGP uses the penalty value to describe the route stability. A larger penalty value indicates a more unstable route. The penalty value increases by 1000 when route oscillation occurs (upon receiving withdraw packets).The penalty value does not increase when the upper limit is reached. The upper limit is determined based on the configured duration value and calculated using the following formula:  $Penalty\ upper\ limit = 2^{(Duration/Half-life)} \times Reusing$ . In addition, the penalty upper limit cannot be greater than 20000. Therefore, the duration, half-life, and reusing values need to be adjusted based on the network conditions. The relationship among these parameters are as follows:

**Usage** Half-life ≤ Duration

**Guide** Reusing ≤ Suppressing ≤ Penalty upper limit

You can also specify only the half-life value. In this case, the duration value is (half-life x 4), the reusing value is 750, and the suppressing value is 2000.

EBGP routes whose penalty value exceeds the suppressing value will be suppressed. Suppressed routes will not be used during BGP route election and will not be advertised to other BGP peers. If route oscillation occurs in suppressed routes, the penalty value will continue to increase until the penalty upper limit is reached.

The penalty value of suppressed routes will decrease by a half each time the half-life time passes. When the penalty value decreases to the reusing value, routes whose attribute is update in the last update will participate in BGP route election again. When the penalty value decreases to 0, routes whose attribute is withdraw in the last update will be deleted from the BGP route table.

**Configuration Examples** The following example enables the routing attenuation and set the attenuation parameters.

```
Ruijie(config-router)# bgp dampening 30 1500 10000 120
```

**Related Commands**

|---------------------------------------------|------------------------------------------------------------------------|
| <b>clear ip bgp dampening</b>               | Clears the BGP suppression and cancels the suppression for the routes. |
| <b>show ip bgp dampening dampened-paths</b> | Displays the suppressed route information.                             |

**Platform**

**Description** None

## 5.24 bgp default ipv4-unicast

Use this command to set the IPv4 unicast address as the default address family. Use the **no** or **default** form of this command to restore the default setting.

**bgp default ipv4-unicast**

**no bgp default ipv4-unicast**

**default bgp default ipv4-unicast**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** The IPv4 unicast address is the default address family.

### Command

**Mode** BGP configuration mode or BGP Scope Global configuration mode

### Usage

**Guide** This command is used to set the default address family of BGP as the IPv4 unicast address.

**Configuration Examples** The following example sets the IPv4 unicast address as the default address family.

```
Ruijie(config-router)#bgp default ipv4-unicast
```

| Related Commands | Command                    | Description                   |
|------------------|----------------------------|-------------------------------|
|                  | <b>address-family ipv4</b> | Enters the IPv4 address mode. |

### Platform

**Description** None

## 5.25 bgp default local-preference

Use this command to set the default local-preference attribute value. Use the **no** or **default** form of this command to restore the default setting.

**bgp default local-preference *value***

**no bgp default local-preference**

**default bgp default local-preference**

| Parameter   | Parameter    | Description                                                 |
|-------------|--------------|-------------------------------------------------------------|
| Description | <i>value</i> | Local priority attribute, in the range from 0 to 4294967295 |

**Defaults** The local preference value is 100 by default.

**Command**

**Mode** BGP configuration mode or BGP Scope configuration mode.

**Usage** The BGP takes the local preference as the foundation to compare with the priority of the path learned from IBGP peers. The larger the local preference value, the higher the priority of the path is.

**Guide** The BGP speaker sends the external route received to the IBGP peers to add the local priority value.

**Configuration** The following example sets the default local-preference attribute value.

**Examples**

```
Ruijie(config-router)# bgp default local-preference 200
```

**Related****Commands**

| Command                                  | Description                                                                                                 |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>show ip bgp</b>                       | Displays the BGP route entry.                                                                               |
| <b>bgp always-compare-med</b>            | Allows comparing the MED value of the path of the peer from different ASs when electing the optimal path.   |
| <b>bgp bestpath med confed</b>           | Allows comparing the MED value of paths of internal peers from AS community when electing the optimal path. |
| <b>bgp bestpath med missing-as-worst</b> | Allows setting the priority of the path without MED attribute as the lowest when electing the optimal path. |

**Platform**

**Description** None

## 5.26 bgp default route-target filter

Use this command to enable the route-target filtering. For the VPNv4 routes, filter the community attributes of the route-target by default. Use the **no** or **default** form of this command to disable this function.

**bgp default route-target filter**

**no bgp default route-target filter**

**default bgp default route-target filter**

**Parameter****Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

This function is enabled by default.

**Command****Mode**

BGP configuration mode, VPNv4/VPNv6 address-family configuration mode, BGP L2VPN EVPN address-family configuration mode or BGP Scope Global configuration mode.

**Usage****Guide**

After receiving the VPNv4 route, use the community attributes list of the route-target to filter and distribute different VRFs. With the no form of this command used, the BGP will receive all VPNv4 routes no matter whether these filtered VPNv4 routes will be received by route-target of local VRF.

With the PE route-reflector-client configured for the BGP, the VPNV4 route will not be processed through the route-target filtering. In this case, whether the BGP is enabled, the actions are the same without the route-target filtering.

**Configuration Examples**

The following example enables the route-target filtering.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# no bgp default route-target filter
```

**Related Commands**

| Command                                | Description                                                                    |
|----------------------------------------|--------------------------------------------------------------------------------|
| <b>neighbor route-reflector-client</b> | Configures the route-reflector-client, and sets itself as the route reflector. |

**Platform**

**Description** N/A

## 5.27 bgp deterministic-med

Use this command to set comparing preferentially the MED values of peer paths from the same AS. By default, the comparison is based on the received order, and the one received the last is compared first. Use the **no** or **default** form of this command to restore the default setting.

**bgp deterministic med**

**no bgp deterministic med**

**default bgp deterministic-med**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command**

**Mode** BGP configuration mode or BGP Scope Global configuration mode

**Usage Guide**

They will be compared with each other according to the sequence the paths are received when the optimal path is selected by default. Execute the following operations in the BGP configuration mode to compare paths of peers from the same AS firstly:

**Configuration Examples**

The following example sets the comparing preferentially MED values.

```
Ruijie(config-router)# bgp deterministic med
```

**Related Commands**

| Command            | Description                   |
|--------------------|-------------------------------|
| <b>show ip bgp</b> | Displays the BGP route entry. |

|                                          |                                                                                                    |
|------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>bgp always-compare-med</b>            | Compares the MED value of paths of peers from different ASs when selecting the optimal path.       |
| <b>bgp bestpath med confed</b>           | Sets the priority of the path without MED attribute as the lowest when selecting the optimal path. |
| <b>bgp bestpath med missing-as-worst</b> | Compares paths of peers from the same AS when selecting the optimal path.                          |

**Platform****Description** None

## 5.28 bgp enforce-first-as

Use this command to reject the UPDATE messages whose first AS\_PATH path section is not the neighbor-configured AS number. Use the **no** or **default** form of this command to disable this function.

**bgp enforce-first-as****no bgp enforce-first-as****default bgp enforce-first-as**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is enabled by default.**Command****Mode** BGP configuration mode or BGP Scope Global configuration mode**Usage****Guide** The AS number of the device is put into the path section by default to update the update message.**Configuration****Examples**

The following example rejects the UPDATE messages whose first AS\_PATH path section is not the neighbor-configured AS number.

```
Ruijie(config-router)# bgp enforce-first-as
```

**Related****Commands**

| Command            | Description                   |
|--------------------|-------------------------------|
| <b>show ip bgp</b> | Displays the BGP route entry. |

**Platform****Description** None

## 5.29 bgp fast-external-fallover

When the network interface used in establishing the connection of the directly-connected EBGP peer fails, use this command to establish the BGP session connection quickly. Use the **no** or **default** form of this command to disable this function.

**bgp fast-external-fallover**

**no bgp fast-external-fallover**

**default bgp fast-external-fallover**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command**

**Mode** BGP configuration mode or BGP Scope Global configuration mode

**Usage**

**Guide** This command takes effect only for the directly-connected EBGP neighbor.

**Configuration** The following example creates the fast BGP session.

**Examples**

```
Ruijie(config-router)# bgp faster-external-fallover
```

| Related  | Command           | Description               |
|----------|-------------------|---------------------------|
| Commands | <b>router bgp</b> | Enables the BGP protocol. |

**Platform**

**Description** None

## 5.30 bgp fast-reroute

Use this command to enable BGP Fast Reroute. Use the **no** or **default** form of this command to restore the default setting.

**bgp fast-reroute**

**no bgp fast-reroute**

**default bgp fast-reroute**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** BGP configuration mode/ BGP IPv4 unicast address family configuration mode/ BGP IPv4 VRF address family configuration mode/ BGP scope global configuration mode.

**Mode**

-  The BGP Fast Reroute function is supported in the BGP IPv4 unicast address family configuration mode and the BGP IPv4 VRF address family configuration mode.
-  Only one backup route will be generated and the next-hop of this backup route cannot be the same as that of the preferred route.

**Usage Guide**

-  When ECMP is enabled, the FRR cannot generate backup route.
-  When this function is enabled in the BGP IPv4 VRF address family configuration mode, the priority of BGP FRR is lower than that of VPN FRR. So when the VPN FRR is enabled in IPv4 VRF configuration mode, BGP FRR does not take effect unless VPN FRR is unable to calculate the backup route.

**Configuration Examples**

The following example enables BGP Fast Reroute.

```
Ruijie(config)# router bgp 65530
Ruijie(config-router)# bgp faster-reroute
```

**Description** N/A

## 5.31 bgp graceful-restart

Use this command to enable the global BGP graceful restart function. Use the **no** or **default** form of this command to disable BGP graceful restart.

**bgp graceful-restart**

**no bgp graceful-restart**

**default bgp graceful-restart**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

By default, BGP graceful restart is enabled so as to help neighbors to perform graceful restart.

**Command**

**Mode**

BGP configuration mode or BGP Scope Global configuration mode

**Usage**

The ability of the BGP is advertised and negotiated through the ability field of the Open message.

**Guide** The ability is negotiated during initially setting up the connection. So both sides must reach the consistency of the ability. If it is not supported by any side, this router device will perform the GR incorrectly.

With the GR function enabled, the connected Open message will carry the GR ability field to perform the negotiation of the GR ability. To implement the GR correctly, the GR function must be enabled on both sides of the neighbors.

 This command does not take effect immediately on all BGP connections that are set up successfully. To negotiate the GR ability immediately, you need to restart the BGP connection to make the local device negotiate the GR ability with the Peer again by using the clear ip bgp command.

The BGP graceful-restart is used to forward data continuously of the whole network, it requires the device to keep the BGP routing entry valid and forward data continuously when restarting the BGP protocol. Supporting the continuous forwarding during the restarting is related to the hardware ability.

**Configuration Examples**

The following example enables the graceful restart function of the global BGP.

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp graceful-restart
```

**Related Commands**

| Command                                  | Description                                              |
|------------------------------------------|----------------------------------------------------------|
| <b>router bgp</b>                        | Enables the BGP protocol.                                |
| <b>bgp graceful-restart restart-time</b> | Configures the restart time of the BGP graceful-restart. |

**Platform**

**Description** N/A

## 5.32 bgp graceful-restart disable

Use this command to disable GR capability of a BGP address family. Use the **no** or **default** form of this command to restore the default setting.

**bgp graceful-restart disable**

**no bgp graceful-restart disable**

**default bgp graceful-restart disable**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

The function is enabled by default.

**Command Mode**

BGP configuration mode, IPv4 unicast address family mode, VPNv4 address family mode, VPNv4 address family mode, BGP L2VPN EVPN address-family configuration mode or BGP Scope

configuration mode

**Usage Guide** When BGP GR function is enabled, the GR capability for all address families is enabled by default, except for address families that do not support GR capability. After GR capability is enabled, you can use this command in the address family mode to disable the address family's GR capability. The Configuration of this command in BGP mode is effective on IPv4 Unicast address family. When BGP GP function is disabled, GR capability is disabled for all address families.

**Configuration** The following example disables the graceful restart function of the BGP IPv4 address family.

```
Examples Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp graceful-restart
Ruijie(config-router)# address-family ipv4
Ruijie(config-router-af)# bgp graceful-restart disable
```

| Configuration Examples | Command                     | Description                          |
|------------------------|-----------------------------|--------------------------------------|
|                        | <b>bgp graceful-restart</b> | Enables BGP's GR capability.         |
|                        | <b>address-family ipv4</b>  | Enters BGP IPv4 address family mode. |

**Platform** N/A  
**Description**

### 5.33 bgp graceful-restart restart-time

Use this command to configure the restart time of the BGP graceful-restart. Use the **no** or **default** form of this command to restore the default setting.

**bgp graceful-restart restart-time** *restart-time*

**no bgp graceful-restart restart-time**

**default bgp graceful-restart restart-time**

| Parameter Description | Parameter           | Description                                                                                                                                                                   |
|-----------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>restart-time</i> | GR Restarter-hoped longest waiting time before re-establishing the connection between the GR Helper and the GR Restarter, in the range from 1 to 3600 in the unit of seconds. |

**Defaults** The default is 120.

**Command**

**Mode** BGP configuration mode or BGP Scope Global configuration mode.

**Usage Guide** The restart time is advertised by GR Restarter to GR Helper, it is GR Restarter-hoped longest waiting time before re-establishing the connection between GR Helper and GR Restarter. After this time, if the BGP connection with GR Restarter is not in Established status, GR Helper will consider

this BGP session failed and will restore the normal BGP. All the routing of the neighbor will be deleted during this period, affecting the data redistribution.

The restart time is advertised in the GR ability field of the BGP Open message. The GR restart time of the two ends of the session is not required to be the same, but it is recommended.

 This command does not take effect immediately on all BGP connections that are set up successfully. To advertise the newly set restart time to the GR helper, you need to restart the BGP connection to negotiate the GR ability again and advertise the restart time by using the `clear ip bgp` command. The configured restart time should not be greater than the Hold Time of the BGP peer, if so, the Hold time will be the restart time when the GR ability is advertised to the BGP peer.

The following example configures the restart time of the BGP graceful-restart.

### Configuration Examples

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp graceful-restart
Ruijie(config-router)# bgp graceful-restart restart-time 150
Ruijie(config-router)# no bgp graceful-restart restart-time
```

### Related Commands

| Command                     | Description                       |
|-----------------------------|-----------------------------------|
| <b>bgp graceful-restart</b> | Enables the BGP graceful-restart. |

### Platform Description

## 5.34 bgp graceful-restart stalepath-time

Use this command to configure the time to help the device keep the route valid when executing the BGP graceful-restart. Use the **no** or **default** form of this command to restore the default setting.

**bgp graceful-restart stalepath-time stalepath-time *time***

**no bgp graceful-restart stalepath-time**

**default bgp graceful-restart stalepath-time**

### Parameter Description

| Parameter   | Description                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>time</i> | Longest time used to keep the stale route valid after restoring the connection with the neighbors, in the range from 1 to 3600 in the unit of seconds |

### Defaults

The default is 360.

### Command Mode

#### Mode

BGP configuration mode

### Usage

This command is configured for the parameters of the GR Helper. The stalepath-time is the longest

**Guide**

time of the GR Helper waiting to receive the EOR mark of the Restarter after restoring the connection with the GR Restarter. When the GR Helper detects that the connection with the GR Restarter fails, the original route of the Restarter is marked as the “Stale”. However these routes are still used for the routing calculation and forwarding.

The GR Helper updates the routes and cancels the “Stale” mark according to route updating information received from the GR Restarter. If routes marked as “Stale” are not updated in the stalepath-time period, they will be deleted. This mechanism is used to avoid failure in convergence of routes when the GR Helper fails to receive the EOR mark of the GR Restarter for a long time.

The following example configures the restart time of the BGP graceful-restart.

**Configuration Examples**

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp graceful-restart
Ruijie(config-router)# bgp graceful-restart stalepath-time 240
```

**Related****Commands**

**Description**

## 5.35 bgp initial-advertise-delay

Use this command to configure the delay period before a BGP device sends its initial updates to peers. Use the **no** form or **default** form of this command to restore the default setting.

**bgp initial-advertise-delay** *delay-time* [ *startup-time* ]

**no bgp initial-advertise-delay**

**default bgp initial-advertise-delay**

Use this command to enable the BGP delayed advertisement upon system restart. Thus, the route will be immediately sent after the prefix-list policy is matched. Use the **no** form or **default** form of this command to restore the default setting.

**bgp initial-advertise-delay prefix-list** *prefix-list-name*

**no bgp initial-advertise-delay prefix-list**

**default bgp initial-advertise-delay prefix-list**

**Parameter****Description**

| Parameter               | Description                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>delay-time</i>       | The delay period, in seconds, before a BGP device sends its updates. The range is from 1 to 600. The default value is 1 second.                                                               |
| <i>startup-time</i>     | The time for the BGP device restart. In the period, the neighbor does not send its updates to peers. The range is from 5 to 584,000. The unit is second and the default value is 600 seconds. |
| <i>prefix-list-name</i> | Name of the prefix-list. It cannot exceed 32 characters.                                                                                                                                      |

**Defaults** The initial advertisement delay is disabled by default.

**Command**

**Mode** BGP configuration mode

This command is used to configure parameters for delayed neighbor route advertisement during device restart.

**delay-time** indicates the longest time for sending a route to a neighbor after the BGP neighbor relationship is established. In normal cases, after the neighbor relationship is established, the first route is advertised immediately and subsequent routes are advertised based on the default time. For details, see the `neighbor advertisement-interval` command. **startup-time** indicates the configurable startup time and starts to count when the configuration command takes effect. Within the time specified by **startup-time**, routes to BGP neighbors are advertised periodically based on **delay-time**. This command can be used to change the route advertisement behavior from the BGP peer to neighbors after device restart.

**Usage Guide**

The prefix-list policy is configured to ensure that partial routes can be normally delivered. The prefix-list policy applies to distributed routes. Matched routes will be normally delivered without being affected by delayed advertisement. For details about the address family scope to which the prefix-list policy applies, see the `neighbor prefix-list` command.

This command is used by the administrator to adjust the BGP route advertisement behavior during device restart based on the hardware conditions, number of neighbors, number of routes, and actual deployment requirements.

**Configuration**

The following example configures initial delay to 60 seconds within 500 seconds after BGP restart.

**Examples**

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp initial-advertise-delay 60 500
```

## 5.37 bgp maxas-limit

Use this command to set the maximum number of ASs in the BGP AS-PATH attribute. Use the **no** or **default** form of the command to restore the default configuration.

**bgp maxas-limit** *number*

**no bgp maxas-limit**

**default bgp maxas-limit**

|                    | Parameter     | Description                                                                         |
|--------------------|---------------|-------------------------------------------------------------------------------------|
| <b>Parameter</b>   |               |                                                                                     |
| <b>Description</b> | <i>number</i> | The maximum number of ASs in the BGP AS-PATH attribute. The range is from 1 to 512. |

**Defaults** No maximum number of ASs is set by default.

**Command**

**Mode** BGP configuration mode/ BGP scope global configuration mode.

**Usage** The routes exceeding the AS number limit are discarded directly, After changing the configuration,

**Guide** use the **clear** command to reset the neighbor and make the configuration take effect.

**Configuration** The following example sets the maximum number of ASs in the BGP AS-PATH attribute to 100.

**Examples**

```
Ruijie(config-router)# bgp maxas-limit 100
```

## 5.38 bgp maximum-prefix

Use this command to restrict the maximum number of routes in the BGP global or specified VRF. Use the **no** or **default** form of the command to restore the default configuration.

**bgp maximum-prefix** *numbers* [ **vrf** *vrf-name* ]

**no bgp maximum-prefix** [ **vrf** *vrf-name* ]

**default bgp maximum-prefix** [ **vrf** *vrf-name* ]

| Parameter Description | Parameter       | Description                                            |
|-----------------------|-----------------|--------------------------------------------------------|
|                       | <i>vrf-name</i> | Indicates name of a specific VRF.                      |
|                       | <i>numbers</i>  | Indicates number of routes. Range: 1 to 4,294,967,295. |

**Defaults** The function is disabled by default.

**Command**

**Mode** BGP configuration mode/ BGP scope global configuration mode.

When a route advertisement in an address family causes the current number of BGP routes to exceed the maximum number, a prompt indicating route overflow in the global or specified VRF is displayed, and the BGP global or specified VRF is set to the overflow state.

The BGP routing information prefix may be introduced by **redistribute**, from a neighbor or from another VRF. In either case, once the BGP routing information prefix of an address family is introduced, the number of BGP global or specified VRF routes reaches the upper limit, the prefix will not increase and a prompt indicating route overflow in the global or specified VRF is displayed, and the BGP global or specified VRF is set to the overflow state.

**Usage****Guide**

Run the **show bgp** { *addressfamily* | **all** } **summary** command to check routing information base status.

If the address family enters the overflow state because the BGP routing information prefix reaches the upper limit, it can be adjusted by **maximum-prefix**.

For IPv4 unicast routes, the routing information prefix may still be received if it is in the overflow state in the following cases:

- 1) The routing information of the same routing prefix already exists in the routing information base;
- 2) A route that covers the prefix (except the default route) already exists in the routing information base, and the next hop of the route is different from the next hop of the newly received route prefix.

**Configuration** The following example sets the maximum number of routes to 100.

**Examples**

```
Ruijie(config)#router bgp 100
Ruijie(config-router)#bgp maximum-prefix 100
```

### 5.39 bgp mp-error-handle session-retain

Use this command to retain BGP sessions when BGP protocol detects errors in multi-protocol route attributes. Use the **no** or **default** form of this command to restore the default setting.

**bgp mp-error-handle session-retain [refresh-timer *time* ]**

**no bgp mp-error-handle session-retain**

**default bgp mp-error-handle session-retain**

**Parameter Description**

| Parameter                        | Description                                                                                                                                       |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>refresh-timer <i>time</i></b> | Configures the waiting time for auto route recovery.<br>The parameter ranges from 10 to 4294967296 in the unit of seconds.<br>The default is 120. |

**Defaults**

By default, BGP sessions will be interrupted when multi-protocol attribute errors are detected.

**Command Mode**

BGP configuration mode or BGP Scope Global configuration mode

**Usage Guide**

By default, when UPDATA packets are received from a neighbor, BGP sessions will be interrupted if multi-protocol attribute errors are detected, which will cause oscillation of routes of all the address families of the neighbor. An address family's route error will affect the stability of routes of other address families. After this command is configured, when an error of the route attribute of an address family occurs, all the route information of the address family and neighbor will be deleted, thus preventing impact on the BGP session and other protocol address families, improving BGP protocol's stability.

The option recovery-time is used to configure the waiting time for auto route recovery. To use the option, the neighbor must support the route refreshing capability. After recovery-time expires, BGP will send a route-refresh message to the neighbor's address family and re-notify the neighbor of the address family's all route information.

**Configuration Examples**

The following example retains BGP sessions when BGP protocol detects errors in multi-protocol route attributes.

```
Ruijie(config-router)# bgp mp-error-handle session-retain
```

Description

## 5.40 bgp nexthop trigger delay

Use this command to configure the delay time for updating the routing table when the nexthop of the BGP route changes. Use the **no** or **default** form of this command to restore the default setting.

**bgp nexthop trigger delay** *delay-time*

**no bgp nexthop trigger delay**

**default bgp nexthop trigger delay**

| Parameter Description | Parameter | Description       |
|-----------------------|-----------|-------------------|
|                       |           | <i>delay-time</i> |

Defaults The default is 5.

Command Mode BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode or BGP Scope configuration mode.

Usage Guide This command is used to configure the delay time for updating the routing table when the nexthop changes, it takes effect when the bgp nexthop trigger enable switch is opened.

Configuration Examples The following example retains BGP sessions when BGP protocol detects errors in multi-protocol route attributes.

```
Ruijie(config-router)# bgp nexthop trigger delay 30
```

## 5.41 bgp nexthop trigger enable

Use this command to enable the nexthop trigger update function. Use the **no** or **default** form of this command to disable this function.

**bgp nexthop trigger enable**

**no bgp nexthop trigger enable**

**default bgp nexthop trigger enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address-family configuration mode, BGP IPv4/IPv6 VRF address-family configuration mode, BGP L2VPN EVPN address family configuration mode, BGP VPNv4/VPNv6 address-family configuration mode or BGP Scope configuration mode.

**Usage**

**Guide** This command is used to enable the nexthop trigger update function.

**Configuration Examples** The following example enables the nexthop trigger update function.

```
Ruijie(config-router)# bgp nexthop trigger enable
```

| Related Commands | Command                          | Description                                                                  |
|------------------|----------------------------------|------------------------------------------------------------------------------|
|                  | <b>Bgp nexthop trigger delay</b> | Sets the delay time for updating the routing table when the nexthop changes. |

**Platform**

**Description** None

## 5.42 bgp notify unsupported-capability

Use this command to enable the neighbor address family capability detection function. Use the **no** or **default** form of this command to restore the default setting.

**bgp notify unsupported-capability**

**no bgp notify unsupported-capability**

**default bgp notify unsupported-capability**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode or BGP Scope Global configuration mode

**Usage Guide** When BGP neighbor address family capability negotiation is not fully consistent, neighbors can still be connected. After this command is configured, when an address family capability supported by the local device is not supported by the neighbor device, Notification packet that carries the address family that does not support the capability will be send.

**Configuration Examples** The following example enables the neighbor address family capability detection function.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp notify unsupported-capability
```

| Configuration Examples | Command                 | Description           |
|------------------------|-------------------------|-----------------------|
|                        | <code>router bgp</code> | Enables BGP protocol. |

**Platform Description** N/A

## 5.43 bgp redistribute-internal

Use this command to control BGP whether to allow redistributing routes learned from IBGP, such as RIP, OSPF and ISIS, to the IGP protocol. Use the **no** or **default** form of this command to disable this function.

**bgp redistribute-internal**

**no bgp redistribute-internal**

**default bgp redistribute-internal**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** IBGP routes are allowed by default to be redistributed to the IGP protocol.

**Command Mode** BGP configuration mode, IPv4/IPv6 Unicast address family configuration mode, IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage Guide** This command is used to control whether IBGP routes are allowed to be redistributed to the IGP protocol.

**Configuration** The following example enables the BGP to learn the redistributing routes from IBGP.

**Examples**

```
Ruijie(config-router)# bgp redistribute-internal
```

**Related  
Commands**

| Command             | Description                                        |
|---------------------|----------------------------------------------------|
| <b>redistribute</b> | Redistributes routes learned from other protocols. |

**Platform**

**Description** None

## 5.44 bgp router-id

Use this command to configure the ID-IP address of the device. Use the **no** or **default** form of this command to restore the default setting.

**bgp router-id** *ip-address*

**no bgp router-id**

**default bgp router-id**

**Parameter  
Description**

| Parameter         | Description |
|-------------------|-------------|
| <i>ip address</i> | IP address  |

**Defaults**

The loop-back interface of the device is selected preferentially by default. If it does not exist, the device route-id of the device is used.

**Command  
Mode**

BGP configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope Global configuration mode.

**Usage  
Guide**

This command is used to configure IP address, the ID of the device when running the BGP protocol.

**Configuration**

The following example configures the ID-IP address of the device.

**Examples**

```
Ruijie(config-router)# bgp router-id 10.0.0.1
```

**Related  
Commands**

| Command                                     | Description                                                         |
|---------------------------------------------|---------------------------------------------------------------------|
| <b>show ip bgp dampening dampened-paths</b> | Displays the suppressed routing information.                        |
| <b>bgp dampening</b>                        | Enables the route dampening function and sets dampening parameters. |

**Platform**

**Description** None

## 5.45 bgp scan-rib disable

Use this command to update the routing table by event triggering. Use the **no** or **default** form of this command to restore the default setting.

**bgp scan-rib disable**

**no bgp scan-rib disable**

**default bgp scan-rib disable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** Timely scan and update is enabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address-family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP L2VPN EVPN address family configuration mode and BGP Scope configuration mode.

**Usage Guide** BGP provides two route update mechanisms: regular-scanning update and event-triggering update. Regular-scanning update indicates that BGP uses an internal timer to start scanning regularly and update the routing table. Event-triggering update indicates that BGP starts scanning and updates the routing table when the BGP configuration commands are changed due to user configuration or the next hop of a BGP route changes.

**Configuration Examples** The following example configures the timely scan for the BGP protocol.

```
Ruijie(config-router)# bgp scan-rib disable
```

| Related Commands | Command              | Description                                      |

## 5.47 `bgp tcp-source-check disable`

Use this command to configure BGP's TCP source check function. Use **no** or **default** form of this command to disable this function.

**bgp tcp-source-check disable**

**no bgp tcp-source-check disable**

**default bgp tcp-source-check disable**

| Parameter | Description |
|-----------|-------------|
| -         | -           |

**Defaults** This function is enabled by default.

**Command Mode** BGP configuration mode or BGP Scope Global configuration mode

**Usage Guide** After TCP source check function is disabled, all TCP connection requests will be received. After TCP connection is established, if no neighbor peer is configured on the local device, Notification packet will be send to refuse the BGP connection.

**Configuration** The following example configures BGP's TCP source check function.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp tcp-source-check disable
```

| Configuration Examples | Command           | Description           |
|------------------------|-------------------|-----------------------|
|                        | <b>router bgp</b> | Enables BGP protocol. |

**Platform** N/A

**Description**

## 5.48 bgp timer accuracy-control

Use this command to configure BGP's internal timer accuracy control. Use **no** or **default** form of this command to restore the default setting.

**bgp timer accuracy-control**  
**no bgp timer accuracy-control**  
**default bgp timer accuracy-control**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode

**Usage Guide** By default, a deviation from the given time will occur on the BGP protocol's timer to prevent concurrent overtime of many timers. You can use this command to configure BGP protocol's timer to strictly implement the given time. It is recommended disabling this function unless necessary.

**Configuration** The following example configures BGP's internal timer accuracy control.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# bgp timer accuracy-control
```

| Configuration Examples | Command           | Description           |
|------------------------|-------------------|-----------------------|
|                        | <b>router bgp</b> | Enables BGP protocol. |

**Platform** N/A

**Description**

## 5.49 bgp update-delay

Use this command to set the maximum delay time of the BGP Speaker before sending the first updating information to neighbors. The **no** or **default** form of the command restores it to the default value. During the BGP graceful-restart, this command is used to update the delay time.

**bgp update-delay** *delay-time*

**no bgp update-delay**

**default bgp update-delay**

| Parameter         | Description                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>delay-time</i> | Maximum delay time of the BGP Speaker before sending its route updating information, in the range from 0 to 3600 in the unit of seconds, 120 seconds by default. For BGP graceful-restart, it is the maximum time of waiting to receive the EOR message of all neighbors, in the range from 1 to 3600 in the unit of seconds. |

**Parameter**  
**Description**

**Defaults** The default is 120.

**Command**

**Mode** BGP configuration mode or BGP Scope Global configuration mode

With the BGP starting up, it first waits some time to connect with its neighbors, and then sends the updating message to these neighbors. After connecting with neighbors, the BGP does not send the updating message to them immediately, but waits some time to receive the updating routing message from all neighbors and then performs routing optimization calculation and finally advertises the route updating message to its neighbors, which improves the convergence time and reduces the calculation consumption. If the software sends the route updating information to its neighbors immediately, it may send the information again when it receives more optimized routes from other neighbors.

**Usage Guide**

The **bgp update-delay** command is used to adjust the initial waiting time of the software, which is the maximum time, from establishing the connection with the first neighbor to performing the routing optimization calculation and sending the route advertisement. When the BGP graceful-restart is enabled, this command is also used to set the maximum waiting time to receive EOR messages from all neighbors. You can increase this value if there are many neighbors or the routing information of the neighbors is huge. If the number of neighbors is 100 and the average amount of routes is 5000, the update sending time that each neighbor completes all the routing is 1 second, then the update of all the routing needs 100 seconds; if the number of neighbors increases to 200, the Update Delay time can be set to 240 seconds, ensuring that all the routing can be updated with the Update Delay period. The specific time is also related to data transmission rate.

**Configuration**  
**Examples**

The following example sets the update-delay time to 200 seconds.

```
Ruijie(config)# router bgp 500
Ruijie(config-router)# bgp graceful-restart
```

```
Ruijie(config-router)# bgp update-delay 200
```

## 5.50 clear bgp all

Use this command to reset all BGP address-families. The content to be reset depends on the further parameters .

**clear bgp all** [ *as number* ] [ **soft** ] [ **in** | **out** ]

| Parameter             | Description                                                                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>none parameter</i> | Resets peer sessions in all address-families.                                                                                                                                                                                                      |
| <i>as-number</i>      | Resets sessions with all members in the specified AS.<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
| <b>in</b>             | Resets the received routing information.                                                                                                                                                                                                           |
| <b>out</b>            | Resets the redistributed routing information.                                                                                                                                                                                                      |
| <b>soft</b>           | Soft-resets all routing information received/sent from/to the specified peer.                                                                                                                                                                      |
| <b>soft in</b>        | Soft-resets the received routing information.                                                                                                                                                                                                      |
| <b>soft out</b>       | Soft-resets the distributed routing information.                                                                                                                                                                                                   |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to reset sessions of all supported address-families, including the vrf session in every address-family.

**Configuration Examples** N/A

## Description

## 5.51 clear bgp all peer-group

Use this command to reset BGP's specific peer group. The reset content is determined by further parameters.

**clear bgp all peer-group** *peer-group-name* [ **soft** ] [ **in** | **out** ]

### Parameter Description

| Parameter              | Description                                      |
|------------------------|--------------------------------------------------|
| <i>peer-group-name</i> | Resets a specific peer group.                    |
| <b>in</b>              | Resets received route information.               |
| <b>out</b>             | Resets allocated route information.              |
| <b>soft</b>            | Soft-resets received and sent route information. |
| <b>soft in</b>         | Soft-resets received route information.          |
| <b>soft out</b>        | Soft-resets allocated route information.         |

### Defaults

-

### Command Mode

Privileged EXEC mode

### Usage Guide

This command will reset replies of all supported address families, including reply connection included in vrf in each address family.

### Description

## 5.52 clear bgp all update-group

Use this command to reset sessions of all members in an update-group.

**clear bgp all update-group** [ *update-group-index* | *peer-address* ] [ **soft** ] [ **in** | **out** ]

### Parameter Description

| Parameter                 | Description                                                      |
|---------------------------|------------------------------------------------------------------|
| <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of |

|                     |                                                                                      |
|---------------------|--------------------------------------------------------------------------------------|
|                     | members need to be reset.                                                            |
| <i>peer-address</i> | Specifies the update-group, to which a peer whose session needs to be reset belongs. |
| -                   | Resets BGP sessions directly if no option is carried.                                |
| <b>in</b>           | Resets received routing information.                                                 |
| <b>out</b>          | Resets distributed routing information.                                              |
| <b>soft</b>         | Soft-resets sent and received routing information.                                   |
| <b>soft in</b>      | Soft-resets received routing information.                                            |
| <b>soft out</b>     | Soft-resets distributed routing information.                                         |

**Command** Privileged EXEC mode

**Mode**

**Default Level** 14

**Usage Guide** This command is used to reset BGP sessions of all members in an update-group.

**Configuration Example** The following example resets routing information received by all peers in an update group to which the peer with the IP address of 1.1.1.1 belongs.

```
Ruijie# clear bgp all update-group 1.1.1.1 in
```

## 5.53 clear bgp ipv4 unicast

Use this command to reset BGP IPv4 unicast address families. The reset content is determined by further parameters.

**clear bgp ipv4 unicast** [ **vrf** *vrf-name* ] { \* | *as-number* | *peer-address* } [ **soft** ] [ **in** | **out** ]

| Parameter Description | Parameter           | Description                                            |
|-----------------------|---------------------|--------------------------------------------------------|
|                       | <i>vrf-name</i>     | VRF name                                               |
|                       | *                   | Resets all peer group sessions under address families. |
|                       | <i>as-number</i>    | Resets sessions with all members in the specified AS.  |
|                       | <i>peer-address</i> | Resets sessions with the specified peer.               |
|                       | <b>in</b>           | Resets received route information.                     |
|                       | <b>out</b>          | Resets allocated route information.                    |
|                       | <b>soft</b>         | Soft-resets received and sent route information.       |
|                       | <b>soft in</b>      | Soft-resets received route information.                |
|                       | <b>soft out</b>     | Soft-resets allocated route information.               |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** This command is the same as **clear ip bgp** in terms of the function and parameters.

**Configuration** N/A

**Examples**

| Configuration Examples | Command | Description |
|------------------------|---------|-------------|
|                        | N/A     | N/A         |

**Platform** N/A

**Description**

## 5.54 clear bgp ipv4 unicast dampening

Use this command to clear the flap information and disable route dampening.

**clear bgp ipv4 unicast [ vrf *vrf-name* ] dampening [ *ip-address* [ *mask* ] ]**

| Parameter       | Description                                |
|-----------------|--------------------------------------------|
| <i>vrf-name</i> | VRF name.                                  |
| -               | Clears the flap information of all routes. |
| <i>address</i>  | IP address                                 |
| <i>mask</i>     | Mask                                       |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage Guide** This command is used to clear the BGP route dampening information and release suppressed routes. This command can be used to restart the BGP route dampening.

**Configuration Examples** The following example clears the flap information and disables route dampening.

```
Ruijie# clear ip bgp dampening 192.168.0.0 255.255.0.0
```

| Related Commands | Command                                     | Description                                                    |
|------------------|---------------------------------------------|----------------------------------------------------------------|
|                  | <b>show ip bgp dampening dampened-paths</b> | Displays the suppressed routing information.                   |
|                  | <b>bgp dampening</b>                        | Enables the route dampening and sets the dampening parameters. |

**Platform**

**Description** None

## 5.55 clear bgp ipv4 unicast external

Use this command to reset all EBGp connections.

**clear bgp ipv4 unicast [ vrf *vrf-name* ] external [ soft ] [ in | out ]**

| Parameter       | Description                                                                   |
|-----------------|-------------------------------------------------------------------------------|
| <i>vrf-name</i> | VRF name.                                                                     |
| <b>in</b>       | Resets received route information.                                            |
| <b>out</b>      | Resets allocated route information.                                           |
| <b>soft</b>     | Soft-resets all routing information received/sent from/to the specified peer. |
| <b>soft in</b>  | Soft-resets the received routing information.                                 |
| <b>soft out</b> | Soft-resets the distributed routing information.                              |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage**

**Guide** This command is used to reset the specified external BGP connection.

**Configuration** The following example resets all EBGp connections.

**Examples** Ruijie# clear bgp ipv4 unicast external in

| Command                      | Description                        |
|------------------------------|------------------------------------|
| <b>clear ip bgp</b>          | Resets the BGP session.            |
| <b>show ip bgp neighbors</b> | Displays the neighbor information. |

**Description** None

## 5.56 clear bgp ipv4 unicast flap-statistics

Use this command to clear the route flap information.

**clear bgp ipv4 unicast [ vrf *vrf-name* ] flap-statistics [ address [ mask ] ]**

| Parameter       | Description                       |
|-----------------|-----------------------------------|
| <i>vrf-name</i> | VRF name.                         |
| -               | Clears all route flap information |
| <i>address</i>  | IP address                        |
| <i>mask</i>     | Mask                              |

**Parameter**

**Description**

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage Guide**

This command can be used only to clear the statistics of unsuppressed routes. It does not release the suppressed routes. To clear all route statistics and release the suppressed routes, run the **clear ip bgp dampening** command.

**Configuration**

The following example clears the route flap information.

**Examples**

```
Ruijie# clear bgp ipv4 unicast flap-statistics
```

**Related Commands**

| Command              | Description                                                         |
|----------------------|---------------------------------------------------------------------|
| <b>bgp dampening</b> | Enables the route dampening function and sets dampening parameters. |
| <b>show ip bgp</b>   | Displays the BGP route entry.                                       |

**Platform**

**Description** None

## 5.57 clear bgp ipv4 unicast peer-group

Use this command to reset the session with all members in the peer group.

**clear bgp ipv4 unicast [ vrf *vrf-name* ] peer-group *peer-group-name* [ soft ] [ in | out ]**

**Parameter Description**

| Parameter              | Description                                                                   |
|------------------------|-------------------------------------------------------------------------------|
| <i>vrf-name</i>        | VRF name                                                                      |
| <i>peer-group-name</i> | Name of the peer group                                                        |
| <b>in</b>              | Resets received route information.                                            |
| <b>out</b>             | Resets allocated route information.                                           |
| <b>soft</b>            | Soft-resets all routing information received/sent from/to the specified peer. |
| <b>soft in</b>         | Soft-resets for the received routing information.                             |
| <b>soft out</b>        | Soft-resets the distributed routing information.                              |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage**

This command resets the BGP session with all members in the peer group.

**Guide**

**Configuration** The following example resets the session with all members in the peer group.

**Examples** Ruijie# clear bgp ipv4 unicast peer-group my-group in

**Related  
Commands**

| Command      | Description                   |
|--------------|-------------------------------|
| clear ip bgp | Resets the BGP session.       |
| show ip bgp  | Displays the BGP route entry. |

**Platform**

**Description** None

## 5.58 clear bgp ipv4 unicast table-map

Use this command to update the table-map setting under the IPv4 unicast address family of BGP.

**clear bgp ipv4 unicast [ vrf *vrf-name* ] table-map**

**Parameter  
Description**

| Parameter       | Description |
|-----------------|-------------|
| <i>vrf-name</i> | VRF name    |

**Defaults** -

**Command  
Mode** Privileged EXEC mode

**Usage Guide** Re-apply table-map setting and update allocated core route table information.

**Configuration** -

**Examples**

**Parameter  
Description**

| Command      | Description                                 |
|--------------|---------------------------------------------|
| clear ip bgp | Resets BGP's IPv4 unicast address families. |

**Platform** -

**Description**

## 5.59 clear bgp ipv4 unicast update-group

Use this command to reset sessions of all members in an update-group in the IPv4 unicast address family.

```
clear bgp ipv4 unicast [ vrf vrf-name ] update-group [ update-group-index | peer-address ] [ soft ]
[ in | out ]
```

**Parameter  
Description**

| Parameter                 | Description                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>           | Specifies the name of a VRF instance. A global VRF instance is used if no VRF instance name is entered. |
| <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset.              |
| <i>peer-address</i>       | Specifies the update-group, to which a peer whose session needs to be reset belongs.                    |
| -                         | Resets BGP sessions directly if no option is carried.                                                   |
| <b>in</b>                 | Resets received routing information.                                                                    |
| <b>out</b>                | Resets distributed routing information.                                                                 |
| <b>soft</b>               | Soft-resets sent and received routing information.                                                      |
| <b>soft in</b>            | Soft-resets received routing information.                                                               |
| <b>soft out</b>           | Soft-resets distributed routing information.                                                            |

**Command  
Mode**

Privileged EXEC mode

**Default Level**

14

**Usage Guide**

This command is used to reset BGP sessions of all members in an update-group in the IPv4 unicast address family.

**Configuration  
Example**

The following example resets routing information received by all peers in an update group to which the peer with the IP address of 1.1.1.1 in the IPv4 unicast address family belongs.

```
Ruijie# clear bgp ipv4 unicast update-group 1.1.1.1 in
```

## 5.60 clear bgp ipv6 unicast

Use this command to reset BGP's IPv6 unicast address families.

```
clear bgp ipv6 unicast [ vrf vrf-name ] { * | as-number | peer-address } [ soft ] [ in | out ]
```

**Parameter  
Description**

| Parameter        | Description                                                                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>  | VRF name                                                                                                                                                                                        |
| *                | Resets all peer group sessions under address families.                                                                                                                                          |
| <i>as-number</i> | Resets sessions with all members in the specified AS.<br>In 10.4(3) or a later version, adds support for 4-byte AS numbers. The new AS number ranges from 1 to 4294967295, or 1 and 65535.65535 |

|                     |                                                  |
|---------------------|--------------------------------------------------|
|                     | in the dotted mode.                              |
| <i>peer-address</i> | Resets sessions with the specified peer.         |
| <b>in</b>           | Resets received routing information.             |
| <b>out</b>          | Resets distributed routing information.          |
| <b>soft</b>         | Soft-resets received and sent route information. |
| <b>soft in</b>      | Soft-resets received route information.          |
| <b>soft out</b>     | Soft-resets allocated route information.         |

**Defaults** -

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** The function is similar with **clear bgp ipv4 unicast**, but applies to different address families.

**Configuration** -

**Examples**

| Configuration Examples | Command                       | Description                                 |
|------------------------|-------------------------------|---------------------------------------------|
|                        | <b>clear bgp ipv4 unicast</b> | Resets BGP's IPv4 unicast address families. |

**Platform** -

**Description**

## 5.61 clear bgp ipv6 unicast dampening

Use this command to clear flap information and disable route dampening.

**clear bgp ipv6 unicast [ vrf vrf-name ] dampening [ ip-address [ mask ] ]**

| Parameter Description | Parameter         | Description                          |
|-----------------------|-------------------|--------------------------------------|
|                       | <i>vrf-name</i>   | VRF name                             |
|                       | -                 | Clears all routes' flap information. |
|                       | <i>ip-address</i> | IP address                           |
|                       | <i>mask</i>       | Mask code                            |

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** You can use this command to clear BGP's route flap information and disable route dampening. The command can restart BGP's route flap.

**Configuration** The following example clears flap information and disables route dampening.

**Examples**

**Configuration Examples**

| Command              | Description                                                         |
|----------------------|---------------------------------------------------------------------|
| <b>bgp dampening</b> | Enables the route dampening function and sets dampening parameters. |

**Platform** -

**Description**

## 5.62 clear bgp ipv6 unicast external

Use this command to reset all EBGP connection of IPv6 unicast address families.

**clear bgp ipv6 unicast [ vrf *vrf-name* ] external [ soft ] [ in | out ]**

**Parameter Description**

| Parameter       | Description                                      |
|-----------------|--------------------------------------------------|
| <i>vrf-name</i> | VRF name                                         |
| <b>in</b>       | Resets received routing information.             |
| <b>out</b>      | Resets distributed routing information.          |
| <b>soft</b>     | Soft-resets received and sent route information. |
| <b>soft in</b>  | Soft-resets received route information.          |
| <b>soft out</b> | Soft-resets allocated route information.         |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** You can use this command to reset all the specified external BGP connection.

**Configuration** The following example resets all EBGP connection of IPv6 unicast address families.

**Examples**

```
Ruijie# clear bgp ipv6 unicast external in
```

**Configuration Examples**

| Command             | Description          |
|---------------------|----------------------|
| <b>clear ip bgp</b> | Resets BGP sessions. |

|                              |                                      |
|------------------------------|--------------------------------------|
| <b>show ip bgp neighbors</b> | Displays BGP neighbors' information. |
|------------------------------|--------------------------------------|

**Platform** -

**Description**

## 5.63 clear bgp ipv6 unicast flap-statistics

Use this command to clear IPv6 unicast address families' route flap statistics.

**clear bgp ipv6 unicast** [ *vrf vrf-name* ] **flap-statistics** [ *address* [ *mask* ] ]

| Parameter Description | Parameter       | Description                                      |
|-----------------------|-----------------|--------------------------------------------------|
|                       | <i>vrf-name</i> | VRF name                                         |
|                       | -               | Clears all route information's flap information. |
|                       | <i>address</i>  | IP address                                       |
|                       | <i>mask</i>     | Mask code                                        |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** This command can only clear statistics of routes that are not damped and will not relieve damped routes. To clear statistics of all route information and relieve damped routes, use the **clear bgp ipv4 unicast dampening** command.

**Configuration Examples** The following example clears IPv6 unicast address families' route flap statistics.

**Examples** Ruijie# clear bgp ipv6 unicast flap-statistics

| Configuration Examples | Command              | Description                                                         |
|------------------------|----------------------|---------------------------------------------------------------------|
|                        | <b>bgp dampening</b> | Enables the route dampening function and sets dampening parameters. |
|                        | <b>show ip bgp</b>   | Displays BGP route entries.                                         |

**Platform** -

**Description**

## 5.64 clear bgp ipv6 unicast peer-group

Use this command to reset sessions with all members in the peer group.

**clear bgp ipv6 unicast** [ vrf *vrf-name* ] **peer-group** *peer-group-name* [ **soft** ] [ **in** | **out** ]

| Parameter Description | Parameter              | Description                                      |
|-----------------------|------------------------|--------------------------------------------------|
|                       | <i>vrf-name</i>        | VRF name                                         |
|                       | <i>peer-group-name</i> | Peer group name                                  |
|                       | <b>in</b>              | Resets received routing information.             |
|                       | <b>out</b>             | Resets distributed routing information.          |
|                       | <b>soft</b>            | Soft-resets received and sent route information. |
|                       | <b>soft in</b>         | Soft-resets received route information.          |
|                       | <b>soft out</b>        | Soft-resets allocated route information.         |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to reset BGP sessions with all members in the peer group.

**Configuration** The following example resets sessions with all members in the peer group.

**Examples** Ruijie# clear bgp ipv6 unicast peer-group my-group in

| Configuration Examples | Command             | Description                 |
|------------------------|---------------------|-----------------------------|
|                        | <b>clear ip bgp</b> | Resets BGP sessions.        |
|                        | <b>show ip bgp</b>  | Displays BGP route entries. |

**Platform** -

**Description**

## 5.65 clear bgp ipv6 unicast table-map

Use this command to update the table-map setting under the IPv6 unicast address family of BGP.

**clear bgp ipv6 unicast [ vrf *vrf-name* ] table-map**

| Parameter Description | Parameter       | Description |
|-----------------------|-----------------|-------------|
|                       | <i>vrf-name</i> | VRF name    |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** -

**Configuration** -

**Examples**

| Configuration Examples | Command             | Description                                 |
|------------------------|---------------------|---------------------------------------------|
|                        | <b>clear ip bgp</b> | Resets BGP's IPv4 unicast address families. |

**Platform** -

**Description**

## 5.66 clear bgp ipv6 unicast update-group

Use this command to reset sessions of all members in an update-group in the IPv6 unicast address family.

**clear bgp ipv6 unicast [ vrf *vrf-name* ] update-group [ *update-group-index* | *neighbor-address* ] [ soft ] [ in | out ]**

| Parameter Description | Parameter                 | Description                                                                                             |
|-----------------------|---------------------------|---------------------------------------------------------------------------------------------------------|
|                       | <i>vrf-name</i>           | Specifies the name of a VRF instance. A global VRF instance is used if no VRF instance name is entered. |
|                       | <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset.              |
|                       | <i>neighbor-address</i>   | Specifies the update-group, to which a peer whose session needs to be reset belongs.                    |

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| -               | Resets BGP sessions directly if no option is carried. |
| <b>in</b>       | Resets received routing information.                  |
| <b>out</b>      | Resets distributed routing information.               |
| <b>soft</b>     | Soft-resets sent and received routing information.    |
| <b>soft in</b>  | Soft-resets received routing information.             |
| <b>soft out</b> | Soft-resets distributed routing information.          |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to reset BGP sessions of all members in an update-group in the IPv6 unicast address family.

**Configuration Example** The following example resets routing information received by all peers in an update group to which the peer with the IP address of 1111::1111 in the IPv6 unicast address family belongs.

```
Ruijie# clear bgp ipv6 unicast update-group 1111::1111 in
```

## 5.67 clear bgp l2vpn evpn

Use this command to reset BGP EVPN address families.

**clear bgp l2vpn evpn** { \* | *as-number* | *neighbor-address* } [ **soft** ] [ **in** | **out** ]

| Parameter Description | Parameter               | Description                                                                                                                                                                                                         |
|-----------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | *                       | Resets all peer group sessions under address families.                                                                                                                                                              |
|                       | <i>as-number</i>        | Resets sessions with all members in the specified AS.<br>In 10.4(3) or a later version, adds support for 4-byte AS numbers. The new AS number ranges from 1 to 4294967295, or 1 and 65535.65535 in the dotted mode. |
|                       | <i>neighbor-address</i> | Resets sessions with the specified peer.                                                                                                                                                                            |
|                       | <b>in</b>               | Resets received route information.                                                                                                                                                                                  |
|                       | <b>out</b>              | Resets allocated route information.                                                                                                                                                                                 |
|                       | <b>soft</b>             | Soft-resets received and sent route information.                                                                                                                                                                    |
|                       | <b>soft in</b>          | Soft-resets received route information.                                                                                                                                                                             |
|                       | <b>soft out</b>         | Soft-resets allocated route information.                                                                                                                                                                            |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** The function is similar with **clear bgp ipv4 unicast**, but applies to different address families.

**Configuration** -

**Examples**

| Configuration Examples | Command | Description                   |
|------------------------|---------|-------------------------------|
|                        |         | <b>clear bgp ipv4 unicast</b> |

**Platform** -

**Description**

## 5.68 clear bgp l2vpn evpn dampening

Use this command to clear flap information and disable route dampening.

**clear bgp l2vpn evpn dampening**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | N/A         |

**Defaults** -

**Command Mode** Privileged EXEC mode

**Usage Guide** You can use this command to clear BGP's route flap information and relieve damped routes. The command can restart BGP's route flap.

**Configuration Examples** The following example clears flap information and disables route dampening.

```
Ruijie# clear bgp l2vpn evpn dampening
```

**Platform** N/A

**Description**

## 5.69 clear bgp l2vpn evpn external

Use this command to reset all EBGP connection of BGP EVPN address families.

**clear bgp l2vpn evpn external [ soft ] [ in | out ]**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | <b>in</b>   |

|                 |                                                  |
|-----------------|--------------------------------------------------|
| <b>out</b>      | Resets allocated route information.              |
| <b>soft</b>     | Soft-resets received and sent route information. |
| <b>soft in</b>  | Soft-resets received route information.          |
| <b>soft out</b> | Soft-resets allocated route information.         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** You can use this command to reset all the specified external BGP connection.

**Configuration** The following example resets all EBGp connection of L2VPN EVPN address families.

**Examples** Ruijie# clear bgp l2vpn evpn external in

**Platform** N/A

**Description**

## 5.70 clear bgp l2vpn evpn flap-statistics

Use this command to clear BGP EVPN address families' route flap statistics.

**clear bgp l2vpn evpn flap-statistics**

| <b>Parameter Description</b>  | Parameter                                                                                                                                                                                                                               | Description |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
|                               | N/A                                                                                                                                                                                                                                     |             |
| <b>Defaults</b>               | N/A                                                                                                                                                                                                                                     |             |
| <b>Command Mode</b>           | Privileged EXEC mode                                                                                                                                                                                                                    |             |
| <b>Usage Guide</b>            | This command can only clear statistics of routes that are not damped and will not relieve damped routes. To clear statistics of all route information and relieve damped routes, use the <b>clear bgp l2vpn evpn dampening</b> command. |             |
| <b>Configuration Examples</b> | The following example clears L2VPN EVPN address families' route flap statistics.                                                                                                                                                        |             |
| <b>Examples</b>               | <pre>Ruijie# clear bgp l2vpn evpn flap-statistics</pre>                                                                                                                                                                                 |             |
| <b>Platform Description</b>   | N/A                                                                                                                                                                                                                                     |             |

## 5.71 clear bgp l2vpn evpn peer-group

Use this command to reset sessions of all members in the peer group.

**clear bgp l2vpn evpn peer-group** *peer-group-name* [ **soft** ] [ **in** | **out** ]

| <b>Parameter Description</b> | Parameter              | Description                                      |
|------------------------------|------------------------|--------------------------------------------------|
|                              | <i>peer-group-name</i> | Peer group name                                  |
|                              | <b>in</b>              | Resets received route information.               |
|                              | <b>out</b>             | Resets allocated route information.              |
|                              | <b>soft</b>            | Soft-resets received and sent route information. |
|                              | <b>soft in</b>         | Soft-resets received route information.          |
|                              | <b>soft out</b>        | Soft-resets allocated route information.         |
| <b>Defaults</b>              | N/A                    |                                                  |
| <b>Command Mode</b>          | Privileged EXEC mode   |                                                  |

**Usage Guide** Use this command to reset BGP sessions of all members in the peer group.

**Configuration Examples** The following example displays that the L2VPN EVPN address family soft-resets received route information of all members in the peer group my-group.

```
Ruijie# clear bgp l2vpn evpn peer-group my-group in
```

**Platform** N/A

**Description**

## 5.72 clear bgp l2vpn evpn update-group

Use this command to reset sessions of all members in an update-group of L2VPN EVPN address family.

**clear bgp l2vpn evpn update-group** [ *update-group-index* | *peer-address* ] [ **soft** ] [ **in** | **out** ]

| Parameter Description | Parameter                 | Description                                                                                |
|-----------------------|---------------------------|--------------------------------------------------------------------------------------------|
|                       | <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset. |
|                       | <i>peer-address</i>       | Specifies the update-group, to which a peer whose session needs to be reset belongs.       |
|                       | -                         | Resets BGP sessions directly if no option is carried.                                      |
|                       | <b>in</b>                 | Resets received routing information.                                                       |
|                       | <b>out</b>                | Resets distributed routing information.                                                    |
|                       | <b>soft</b>               | Soft-resets sent and received routing information.                                         |
|                       | <b>soft in</b>            | Soft-resets received routing information.                                                  |
|                       | <b>soft out</b>           | Soft-resets distributed routing information.                                               |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to reset BGP sessions of all members in an update-group of L2VPN EVPN address family.

**Configuration Example** The following example resets routing information received by all peers in an update group of L2VPN EVPN address family to which the peer with the IP address of 1.1.1.1 belongs.

```
Ruijie# clear bgp l2vpn evpn update-group 1.1.1.1 in
```

## 5.73 clear evpn conflict mac

Use this command to clear MAC information and other statistics of conflicts occurring in EVPN.

**clear evpn conflict mac** [ *vni-id* ]

| Parameter Description | Parameter     | Description                                                                              |
|-----------------------|---------------|------------------------------------------------------------------------------------------|
|                       | <i>vni-id</i> | Clears MAC information and other statistics of conflicts occurring on a specified L2VNI. |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** This command is used to clear conflict MAC information and re-advertise the EVPN routes corresponding to the conflict MAC.

**Configuration Example** The following example clears all conflict MAC information.

**Example**

```
Ruijie# clear evpn conflict mac
```

## 5.74 clear ip bgp

Use this command to reset the BGP session.

**clear ip bgp** [ *vrf vrf-name* ] { \* | *as-number* / *peer-address* } [ *soft* ] [ *in* | *out* ]

| Parameter Description | Parameter        | Description                                                                                                                                                                                                                                     |
|-----------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>vrf-name</i>  | VRF name.                                                                                                                                                                                                                                       |
|                       | *                | Resets all the current BGP sessions and the OVERFLOW status of BGP ipv4 unicast address family.                                                                                                                                                 |
|                       | <i>address</i>   | Resets the BGP session with the specified peer.                                                                                                                                                                                                 |
|                       | <i>as number</i> | Resets sessions with all members in the specified AS. In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new range of the new AS notation is from 1 to 4294967295, represented as 1 to 65535.65535 in dot mode. |
|                       | <b>in</b>        | Reset the received routing information.                                                                                                                                                                                                         |
|                       | <b>out</b>       | Reset the distributed routing information.                                                                                                                                                                                                      |
|                       | <b>soft</b>      | Soft-reset all routing information received/sent from/to the specified peer                                                                                                                                                                     |
|                       | <b>soft in</b>   | Soft-reset the received routing information.                                                                                                                                                                                                    |
|                       | <b>soft out</b>  | Soft-reset the distributed routing information.                                                                                                                                                                                                 |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

At any time, once the routing policy or BGP configuration changes, an effective way must be available to implement the new routing policy or configuration. Traditional measure is to close the BGP connection and establish a new one.

This product supports implementing a new routing strategy without closing the BGP session connection by soft-resetting BGP.

**Usage**

For the peer that does not support the route refresh function, you may run the **neighbor soft-reconfiguration inbound** command to keep a copy of original routing information of every specified BGP peer on the local BGP speaker. This will consume some resources.

**Guide**

You can use the **show ip bgp neighbors** command to see whether the BGP peer supports the route refresh function. If it is supported, you need not to execute the **neighbor soft-reconfiguration inbound** command when the inbound routing strategy changes.

 All connected BGP routers must support the route refresh function to execute this command. This product supports the route refresh function.

**Configuration**

The following example resets the BGP session.

**Examples**

```
Ruijie# clear bgp ipv4 unicast *
```

## 5.75 clear ip bgp dampening

Use this command to clear the dampening information and disable route dampening.

```
clear ip bgp [ vrf vrf-name ] dampening [ ip-address [ mask ] ]
```

**Parameter Description**

| Parameter       | Description |
|-----------------|-------------|
| <i>vrf-name</i> | VRF name    |
| <i>address</i>  | IP address  |
| <i>mask</i>     | Mask        |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage** This command is used to clear the BGP route flap information and disable route dampening. This command can be used to restart BGP route dampening.

**Configuration** The following example clears the dampening information and disables route dampening.

**Examples** Ruijie# clear ip bgp dampening 192.168.0.0 255.255.0.0

|                         | Command                              | Description                                                         |
|-------------------------|--------------------------------------|---------------------------------------------------------------------|
| <b>Related Commands</b> | show ip bgp dampening dampened-paths | Displays the suppressed routing information.                        |
|                         | bgp dampening                        | Enables the route dampening function and sets dampening parameters. |

**Platform**  
**Description** None

## 5.76 clear ip bgp external

Use this command to reset all EBGp connections.

**clear ip bgp [ vrf *vrf-name* ] external [ soft ] [ in | out ]**

|                              | Parameter       | Description                                      |
|------------------------------|-----------------|--------------------------------------------------|
| <b>Parameter Description</b> | <i>vrf-name</i> | VRF name.                                        |
|                              | in              | Reset the received routing information.          |
|                              | out             | Reset the distributed routing information.       |
|                              | soft in         | Soft-resets the received routing information.    |
|                              | soft out        | Soft-resets the distributed routing information. |

**Defaults** N/A

**Command**  
**Mode** Privileged EXEC mode

**Usage**  
**Guide** This command is used to reset the specified external BGP connection.

**Configuration** The following example resets all EBGp connections.

**Examples** Ruijie# clear ip bgp external in

|                         | Command               | Description                        |

**Platform****Description** None

## 5.77 clear ip bgp flap-statistics

Use this command to clear the routes vibration statistics of the IPv4 unicast address family.

```
clear ip bgp [ vrf vrf-name ] flap-statistics [ ip-address [ mask ] ]
```

|                                        | Parameter       | Description |
|----------------------------------------|-----------------|-------------|
| <b>Parameter</b><br><b>Description</b> | <i>vrf-name</i> | VRF name.   |
|                                        | <i>address</i>  | IP address  |
|                                        | <i>Mask</i>     | Mask        |

**Defaults** N/A**Command****Mode** Privileged EXEC mode**Usage****Guide**

This command can be used only to clear statistics of unsuppressed routes. It does not release the suppressed routes. To clear all route statistics and release the suppressed routes, run the **clear ip bgp dampening** command.

**Configuration**

The following example clears the routes vibration statistics of the IPv4 unicast address family.

**Examples**

```
Ruijie# clear ip bgp flap-statistics
```

|                                   | Command              | Description                                                         |
|-----------------------------------|----------------------|---------------------------------------------------------------------|
| <b>Related</b><br><b>Commands</b> | <b>bgp dampening</b> | Enables the route dampening function and sets dampening parameters. |
|                                   | <b>show ip bgp</b>   | Displays the BGP route entry.                                       |

**Platform****Description** None

## 5.78 clear ip bgp peer-group

Use this command to reset the session with all members in the peer group.

```
clear ip bgp [ vrf vrf-name ] peer-group peer-group-name [ soft ] [ in | out ]
```

|                                        | Parameter              | Description                                |
|----------------------------------------|------------------------|--------------------------------------------|
| <b>Parameter</b><br><b>Description</b> | <i>vrf-name</i>        | VRF name.                                  |
|                                        | <i>peer-group-name</i> | Name of the peer group                     |
|                                        | <b>in</b>              | Reset the received routing information.    |
|                                        | <b>out</b>             | Reset the distributed routing information. |

|                 |                                                                              |
|-----------------|------------------------------------------------------------------------------|
| <b>soft</b>     | Soft-resets all routing information received/sent from/to the specified peer |
| <b>soft in</b>  | Soft-resets the received routing information.                                |
| <b>soft out</b> | Soft-resets the distributed routing information.                             |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage**

**Guide** This command resets the BGP session with all members in the peer group.

**Configuration** The following example resets the session with all members in the peer group.

**Examples**

```
Ruijie# clear ip bgp peer-group my-group in
```

**Related  
Commands**

| Command             | Description                   |

| <b>clear ip bgp</b> | Resets the BGP session.       |
| <b>show ip bgp</b>  | Displays the BGP route entry. |

**Platform**

**Description** None

## 5.79 clear ip bgp table-map

Use this command to update the table-map's route information applied by IPv4 unicast address family.

**clear ip bgp [vrf *vrf-name*] table-map**

| Parameter          | Parameter       | Description |
|--------------------|-----------------|-------------|
| <b>Description</b> | <i>vrf-name</i> | vrf name    |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage**

**Guide** This command is used to update the route information of the applied table-map.

**Configuration** The following example updates the table-map's route information applied by IPv4 unicast address family.

**Examples**

```
Ruijie# clear ip bgp table-map
```

| Related<br>Commands | Command            | Description                   |

**Platform**  
**Description**        None

## 5.80 clear ip bgp update-group

Use this command to reset sessions of all members in an update-group in the IPv4 unicast address family.

**clear ip bgp** [ *vrf vrf-name* ] **update-group** [ *update-group-index* | *neighbor-address* ] [ **soft** ] [ **in** | **out** ]

| Parameter<br>Description | Parameter                 | Description                                                                                             |
|--------------------------|---------------------------|---------------------------------------------------------------------------------------------------------|
|                          | <i>vrf-name</i>           | Specifies the name of a VRF instance. A global VRF instance is used if no VRF instance name is entered. |
|                          | <i>update-group-index</i> | Specifies the index of an update-group, in which the sessions of members need to be reset.              |
|                          | <i>neighbor-address</i>   | Specifies the update-group, to which a peer whose session needs to be reset belongs.                    |
|                          | -                         | Resets BGP sessions directly if no option is carried.                                                   |
|                          | <b>in</b>                 | Resets received routing information.                                                                    |
|                          | <b>out</b>                | Resets distributed routing information.                                                                 |
|                          | <b>soft</b>               | Soft-resets sent and received routing information.                                                      |
|                          | <b>soft in</b>            | Soft-resets received routing information.                                                               |
|                          | <b>soft out</b>           | Soft-resets distributed routing information.                                                            |

**Command Mode**        Privileged EXEC mode

**Default Level**    14

**Usage Guide**        This command is used to reset BGP sessions of all members in an update-group in the IPv4 unicast address family.

**Configuration Example**    The following example resets routing information received by all peers in an update group to which the peer with the IP address of 1.1.1.1 in the IPv4 unicast address family belongs.

```
Ruijie# clear ip bgp update-group 1.1.1.1 in
```

## 5.81 default-information originate

Use this command to enable BGP to distribute the default route. Use the **no** form of this command to restore the default setting.

**default-information originate**

**[no] default-information originate**

**default default-information originate**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 address family configuration mode, BGP IPv4 VRF configuration mode, BGP IPv6 VRF configuration mode

**Usage Guide** This command is used to control whether the redistributed default route is effective, and this command needs to be configured together with the **redistribute** command. It takes effect only when a default route exists in the redistributed route.

This command is similar to the **network** command. The difference is that in the process of configuring the former, the **redistribute** command must be configured explicitly to redistribute the default route, only in this case, the redistributed default route is effective. For the later command, the IGP must have the default route.

**Configuration Examples** The following example enables BGP to distribute the default route.

```
Ruijie(config-router)# default-information originate
```

| Related Commands | Command             | Description                             |
|------------------|---------------------|-----------------------------------------|
|                  | <b>network</b>      | Configures routes to be advertised.     |
|                  | <b>redistribute</b> | Redistributes routes of other protocol. |

**Platform**

**Description** None

## 5.82 default-metric

Use this command to set the metric for route redistribution. Use the **no** or **default** form of this command to restore the default setting.

**default-metric *number***

**no default-metric**

**default default-metric**

| Parameter   | Parameter     | Description                                      |
|-------------|---------------|--------------------------------------------------|
| Description | <i>number</i> | Metric number, in the range from 1 to 4294967295 |

**Defaults** No metric is set by default.

**Command Mode** BGP configuration mode, BGP IPv4/ IPv6 Unicast address family configuration mode, BGP IPv4/ IPv6 VRF address family configuration mode or BGP Scope configuration mode.

This command sets the metric of routes to be redistributed for integrity.

### Usage

#### Guide

-  The metric set by the command cannot cover that set by the **redistribute metric** command. The value is 0 when the default metric applies to redistributed connected routes.

**Configuration Examples** The following example sets the metric for route redistribution.

```
Ruijie(config-router)# default-metric 45
```

### Related Commands

| Command             | Description                             |
|---------------------|-----------------------------------------|
| <b>redistribute</b> | Redistributes routes of other protocol. |

## 5.83 distance bgp

Use this command to set different management distances for different types of BGP routes. Use the **no** or **default** form of this command to restore the default setting.

**distance bgp** *external-distance internal-distance local-distance*

**no distance bgp**

**default distance bgp**

| Parameter                | Description                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>external-distance</i> | Route management distance learned from EBGp peers, in the range from 1 to 255                                                                                                                                                           |
| <i>internal-distance</i> | Route management distance learned from IBGP peers, in the range from 1 to 255                                                                                                                                                           |
| <i>local-distance</i>    | Specifies the management distance of route learned from peers. However, the optimal one can be learned from the IGP. In general, these routes are indicated by the Network Backdoor command.<br>The value is in the range from 1 to 255 |

### Defaults

The parameter defaults are as follows:

*external-distance* - 20

*internal-distance - 200*  
*local-distance - 200*

**Command**

**Mode** BGP configuration mode or BGP Scope configuration mode.

It is not recommended to change the management distance of the BGP route. If it is necessary, observe the following points:

- Usage**
- The management distance of "external-distance" must be shorter than those of other IGP routing protocols (such as OSPF and RIP);
  - The internal-distance and local-distance should have longer management distances than other IGP routing protocols.
- Guide**

**Configuration** The following example sets different management distances for different types of BGP routes.

**Examples** Ruijie(config-router)# distance bgp 20 20 200

| Command                                      | Description                                                                                         |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <b>neighbor soft-reconfiguration inbound</b> | Restarts the BGP session and reserves the unchanged route information sent by the BGP peer (group). |
| <b>show ip bgp</b>                           | Displays the BGP route entry.                                                                       |

**Description** None

## 5.84 evpn

Use this command to enter EVPN configuration mode. Use the **no** or **restore** form of this command to restore the default settings.

**evpn**

**no evpn**

**default evpn**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** By default, the EVPN configuration mode is disabled.

**Command**

**Mode** Global configuration mode

**Usage** Use this command to enter EVPN configuration mode. Use the **exit** command to exit the EVPN configuration mode

**Guide**

**Configuration** The following example enters EVPN configuration mode.

**Examples**

```
Ruijie(config)# evpn
```

**Platform**

**Description** N/A

## 5.85 exit-address-family

Use this command to exit BGP address-family configuration mode.

### exit-address-family

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command**

**Mode** BGP address-family configuration mode

**Usage Guide** This command can be used to exit from various address-family modes of BGP to BGP configuration mode.

**Configuration** The following example exits the BGP address-family configuration mode.

**Examples**

```
Ruijie(config-router-af)#exit-address-family
```

## 5.87 import map(EVPN VNI)

Use this command to configure the route map for importing the remote EVPN routes to the local VNI instance. Use the **no** form of this command to delete the route map for importing the remote EVPN routes to the local VNI instance. Use the **default** form of this command to restore the default settings.

**import map** *route-map-name*

**no import map**

**default import map**

| Parameter            | Parameter                                                                                                                                                                             | Description           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| <b>Description</b>   | <i>route-map-name</i>                                                                                                                                                                 | Name of the route map |
| <b>Defaults</b>      | No route map is configured for importing the remote EVPN routes to the local VNI instance by default.                                                                                 |                       |
| <b>Command Mode</b>  | EVPN VNI configuration mode.                                                                                                                                                          |                       |
| <b>Default Level</b> | 14                                                                                                                                                                                    |                       |
| <b>Usage Guide</b>   | This command is used to filter the remote EVPN routes to be imported to the local VNI instance, or modify the attribute of the remote EVPN routes imported to the local VNI instance. |                       |

This command supports only one route map, and the old configuration is overwritten by the new configuration.

**Configuration Examples** The following example configures the route map map1 for importing the remote EVPN routes to the local VNI instance vni 1.

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 1
Ruijie(config-evpn-vni)# import map map1
```

**Verification** Run the **show running-config** command to display the configurations.

## 5.88 maximum-paths

Use this command to configure the number of equivalent paths of the EBGP/IBGP multipath load balancing function. Use the no form of this command to disable the EBGP/IBGP multipath load balancing function. Use the default form of this command to restore the default settings.

**maximum-paths** { **ebgp** | **ibgp** } *number*

**no maximum-paths** { **ebgp** | **ibgp** }

**default maximum-paths** { **ebgp** | **ibgp** }

| Parameter Description | Parameter   | Description                                                                                                                                                                                                  |
|-----------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>ebgp</b> | Specifies the number of equivalent paths of the EBGP multipath load balancing function.                                                                                                                      |
|                       | <b>ibgp</b> | Specifies the number of equivalent paths of the IBGP multipath load balancing function.                                                                                                                      |
|                       | number      | Indicates the maximum number of equivalent paths. The minimum value is 1, and the maximum value depends on the device capability. If the value is 1, the EBGP multipath load balancing function is disabled. |

**Defaults** Equivalence of multiple BGP paths is not supported by default.

**Command Mode** BGP configuration mode, BGP IPv4 Unicast address family configuration mode, BGP IPv6 Unicast address family configuration mode, and BGP Scope Global configuration mode

**Default Level** 14

**Usage Guide** The maximum-paths ebgp command is also used to configure equivalence of confederation EBGP multiple paths and local inter-VRF import routes.  
IBGP and EBGP routes cannot form equivalent routes.

**Configuration Examples** The following example configures EBGP load balancing and sets the maximum number of equivalent routes to 2.

```
Ruijie(config)# router bgp 65530
Ruijie(config-router)# maximum-paths ebgp 2
```

**Verification** Run the show running-config command to display the BGP configurations.

## 5.89 maximum-prefix

Use this command to limit the maximum number of prefixes in the routing database in the address family. Use the **no** or **default** form of this command to restore the default setting.

**maximum-prefix** *maximum*

**no maximum-prefix**

**default maximum-prefix**

| Parameter      | Description                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------|
| <i>maximum</i> | The maximum number of prefixes in the routing database in the address family, in the range from 1 to 4294967295 |

**Defaults** The maximum number is not limited by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF configuration mode, BGP L2VPN EVPN address family configuration mode or BGP Scope configuration mode.

In a BGP address family, routing prefixes may be introduced through redistribution or learnt from neighbors, or other VRFs. Once routing prefixes in the BGP address family reaches the maximum number, this address family will enter to the overflow state.

Use the **show bgp { addressfamily | all } summary** command to display the state of routing database.

It is necessary to reconfigure BGP for state clearing, or use the **clear bgp { addressfamily | all } \*** command to reset the address family.

### Usage Guide

 When the address family is overflow as the number of prefixes reaches the maximum number, you can adjust maximum-prefix.

 Maximum-prefix will not filter the routing information generated by the network and aggregate commands.

IPv4 unicast routes can receive the routing prefix in the following conditions even in the Overflow state:

The route information of the same routing prefix exists in the address database.

One route that overwrites this prefix (except for the default route) exists in the address database and the next-hop of this route is different from that of the newly received routing prefix.

The following example sets the maximum number of prefixes in the BGP routing database in the ipv4 multicast address family.

**Configuration Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# address-family ipv4 multicast
Ruijie(config-router-af)# maximum-prefix 65535
```

**Related Commands**

| Command                              | Description                                               |
|--------------------------------------|-----------------------------------------------------------|
| <b>clear bgp all</b>                 | Resets BGP's all address families.                        |
| <b>clear bgp ipv4 mdt</b>            | Resets BGP's ipv4 mdt address families.                   |

| <b>clear bgp ipv6 unicast</b>        | Resets BGP's ipv6 unicast address families.               |
| <b>clear bgp vpnv4 unicast</b>       | Resets BGP's vpnv4 unicast address families.              |
| <b>show bgp all summary</b>          | Displays summary of BGP's all address families.           |
| <b>show bgp ipv4 mdt summary</b>     | Displays summary of BGP's ipv4 mdt address families.      |
| <b>show bgp ipv4 unicast summary</b> | Displays summary of BGP's ipv4 unicast address families.  |
| <b>show bgp ipv6 unicast summary</b> | Displays summary of BGP's ipv6 unicast address families.  |
| <b>show bgp vpnv4 summary</b>        | Displays summary of BGP's vpnv4 unicast address families. |

**Platform**

**Description** N/A

## 5.90 neighbor activate

Use this command to activate the neighbor or peer group in the current address mode. Use the **no** or **default** form of this command to disable this function.

**neighbor {peer-address | peer-group-name} activate**

**no neighbor {peer-address | peer-group-name} activate**

**default neighbor { peer-address | peer-group-name } activate**

**Parameter Description**

| Parameter              | Description                                          |
|------------------------|------------------------------------------------------|
| <i>peer-address</i>    | IP address of the peer, IPv4 address or IPv6 address |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters        |

**Defaults**

This function is enabled in IPv4 address family mode by default.

**Command Mode**

BGP configuration mode, BGP IPv4/ IPv6 Unicast address family configuration mode, BGP IPv4/ IPv6 VRF address family configuration mode, BGP L2VPN EVPN address family configuration

mode, or BGP Scope configuration mode.

**Usage** The function is enabled by default for IPv4 address families. You need to set this command in other address-family configuration modes for exchanging routes.

**Guide**

The following example activates the neighbor or peer group in the current address mode.

**Configuration Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 100
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 10.0.0.1 activate
```

**Related Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.91 neighbor advertisement-interval

Use this command to set the time interval to send the BGP route update message. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** { *peer-address* | *peer-group-name* } **advertisement-interval** *seconds*

**no neighbor** { *peer-address* | *peer-group-name* } **advertisement-interval**

**default neighbor** { *peer-address* | *peer-group-name* } **advertisement-interval**

**Parameter Description**

| Parameter              | Description                                                                       |
|------------------------|-----------------------------------------------------------------------------------|
| <i>peer address</i>    | IP address of the peer                                                            |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters                                     |
| <i>seconds</i>         | Time interval to send the route update message in the range from 0 to 600 seconds |

**Defaults**

IBGP connection: 15 seconds  
EBGP connection: 30 seconds

**Command Mode**

BGP configuration mode, BGP IPv4/ IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage** If you have specified the BGP peer group, all members of the peer group will adopt the settings of the command.

**Guide**

**Configuration** The following example sets the time interval to send the BGP route update message.

**Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 100
Ruijie(config-router)# neighbor 10.0.0.1 advertisement-interval 10
```

**Related Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.92 neighbor allowas-in

Use this command to allow the PE to receive messages with the same AS number as itself. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **allowas-in** *number*

**no neighbor** {*peer-address* | *peer-group-name*} **allowas-in**

**default neighbor** {*peer-address* | *peer-group-name*} **allowas-in**

**Parameter Description**

| Parameter              | Description                                                                 |
|------------------------|-----------------------------------------------------------------------------|
| <i>peer address</i>    | IP address of the peer                                                      |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters                               |
| <i>number</i>          | Number of the AS number duplication in the range from 1 to 10, 3 by default |

**Defaults**

This function is disabled by default.

**Command Mode**

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode or BGP Scope configuration mode.

**Usage Guide**

A typical application is spoke\_hub mode. Execute this command on the PE to enable it to receive and then send the advertised address prefix. Configure two VRFs on the PE. One VRF receives the routes of all PEs and advertises them to the CE; the other VRF receives the routes advertised by the CE and advertises them to all PEs.

This command applies to IBGP or EBGP peers.

**Configuration Examples**

The following example allows the PE to receive messages with the same AS number as itself.

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 100
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# neighbor 10.1.1.1 allowas-in
```

|                     | Command                   | Description               |

**Platform**  
**Description** None

## 5.93 neighbor as-originate-interval

Use this command to configure the interval that the device advertises local original BGP routes to the peer (group). Use the **no** or **default** form of this command to restore the default setting.

**neighbor** { *peer-address* | *peer-group-name* } **as-origination-interval** *seconds*

**no neighbor** { *peer-address* | *peer-group-name* } **as-origination-interval**

**default neighbor** { *peer-address* | *peer-group-name* } **as-origination-interval**

|                          | Parameter              | Description                                                                                                                                     |
|--------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter<br>Description | <i>peer address</i>    | IP address of the peer.                                                                                                                         |
|                          | <i>peer-group-name</i> | Name of the peer group, containing up to 32 characters.                                                                                         |
|                          | <i>seconds</i>         | The interval at which the device advertises local original BGP routes to the peer (group), in the range from 1 to 65535 in the unit of seconds. |

**Defaults** The default interval is 1.

**Command Mode** BGP configuration mode/ BGP IPv4 VRF address family configuration mode/ BGP IPv6 VRF address family configuration mode/ BGP scope global configuration mode.

**Usage Guide** If you specify a peer group name in this command, the configuration takes effect on all members of the peer group.

The following example configures the interval at which the device advertises local original BGP routes to the peer in the BGP IPv4 VRF address family configuration mode.

**Configuration Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# address-family ipv4 vrf vpn1
Ruijie(config-router-af)# neighbor 10.0.0.1 remote-as 100
Ruijie(config-router-af)# neighbor 10.0.0.1 as-origination-interval 10
```

## Description

## 5.94 neighbor default-originate

Use this command to allow the BGP speaker to advertise the default route to the peer (group). Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **default-originate** [**route-map** *map-tag*]

**no neighbor** {*peer-address* | *peer-group-name*} **default-originate** [**route-map** *map-tag*]

**default neighbor** { *peer-address* | *peer-group-name* } **default-originate** [ **route-map** *map-tag* ]

|             | Parameter              | Description                                   |
|-------------|------------------------|-----------------------------------------------|
| Parameter   | <i>peer address</i>    | IP address of the peer                        |
| Description | <i>peer-group-name</i> | Name of the peer group of up to 32 characters |
|             | <i>map-tag</i>         | Name of the route-map of up to 32 characters  |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, or BGP Scope configuration mode

## Usage Guide

This command does not requires the default route but sends a default route whose next-hop address is the local address to neighbors.

If you have specified the BGP peer group, all members of the peer group will adopt the settings of the command. If you set the command for a member in the peer, this command will overwrite the settings on the peer group.

## Configuration Examples

The following example allows the BGP speaker to advertise the default route to the peer (group).

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 80
Ruijie(config-router)# neighbor 10.1.1.1 default-originate
```

|                  | Command                   | Description               |
|------------------|---------------------------|---------------------------|
| Related Commands | <b>router bgp</b>         | Enables the BGP protocol. |
|                  | <b>neighbor remote-as</b> | Configures the BGP peer.  |

## Platform

**Description** None

## 5.95 neighbor description

Use this command to set a descriptive sentence for the specified peer (group). Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **description** *text*

**no neighbor** {*peer-address* | *peer-group-name*} **description**

**default neighbor** { *peer-address* | *peer-group-name* } **description**

|             | Parameter              | Description                                                 |
|-------------|------------------------|-------------------------------------------------------------|
| Parameter   | <i>peer address</i>    | IP address of the peer                                      |
| Description | <i>peer-group-name</i> | Name of the peer group of up to 32 characters               |
|             | <i>text</i>            | Descriptive text of the peer (group) of up to 80 characters |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode and BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage Guide** This command is used to add descriptive characters for the peer (group). This may help remember features and characteristics of the peer (group).

The following example sets a descriptive sentence for the specified peer (group).

**Configuration**

```
Ruijie(config)# router bgp 60
```

**Examples**

```
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 80
```

```
Ruijie(config-router)# neighbor 10.1.1.1 description xyz.com
```

**Related Commands**

|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.96 neighbor distribute-list

Use this command to implement the routing policy based on the ACL when receiving/sending route information from/to the specified BGP peer. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** { *peer-address* | *peer-group-name* } **distribute-list** { *access-list-number* } { **in** | **out** }

**no neighbor** { *peer-address* | *peer-group-name* } **distribute-list** { *access-list-number* } { **in** | **out** }

**default neighbor** { *peer-address* | *peer-group-name* } **distribute-list** { *access-list-number* | *access-list-name* } { **in** | **out** }

|             | Parameter                 | Description                                   |
|-------------|---------------------------|-----------------------------------------------|
| Parameter   | <i>peer address</i>       | IP address of the peer                        |
| Description | <i>peer-group-name</i>    | Name of the peer group of up to 32 characters |
|             | <i>access-list-number</i> | ACL number                                    |

|            |                                                      |
|------------|------------------------------------------------------|
| <b>in</b>  | Specifies the ACL for filtering the incoming routes. |
| <b>out</b> | Specifies the ACL for filtering the outgoing routes. |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode or BGP Scope configuration mode.

For in rule or out rule, this command cannot be used together with the **neighbor prefix-list** command. Only one of them can take effect.

**Usage Guide** If you have specified the BGP peer group, all members of the peer group will adopt the settings. If you set the **neighbor distribute-list** command for a member in the peer, this command will overwrite the settings on the peer group.

You can set different filtering policies in different address-family configuration modes to control routes.

The following example implements the routing policy based on the ACL when receiving/sending route information from/to the specified BGP peer.

**Configuration Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.1.1.1 remote-as 80
Ruijie(config-router)# neighbor 10.1.1.1
distribute-list bgp-filter in
```

|                         | Command                   | Description                                   |
|-------------------------|---------------------------|-----------------------------------------------|
| <b>Related Commands</b> | <b>router bgp</b>         | Enables the BGP protocol.                     |
|                         | <b>neighbor remote-as</b> | Configures the BGP peer.                      |
|                         | <b>ip access-list</b>     | Creates a standard IP ACL or extended IP ACL. |

**Platform Description** None

## 5.97 neighbor ebgp-multihop

Use this command to allow establishing BGP connection between EBGp peers that are not directly connected. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {peer-address | peer-group-name} **ebgp-multihop** [ttl]

**no neighbor** {peer-address | peer-group-name} **ebgp-multihop** [ttl]

**default neighbor** { peer-address | peer-group-name } **ebgp-multihop** [ ttl ]

|                              | Parameter       | Description                                   |
|------------------------------|-----------------|-----------------------------------------------|
| <b>Parameter Description</b> | peer address    | IP address of the peer                        |
|                              | peer-group-name | Name of the peer group of up to 32 characters |

|            |                                    |
|------------|------------------------------------|
| <i>ttl</i> | Maximum hops in the range 1 to 255 |
|------------|------------------------------------|

**Defaults**

The BGP connection is allowed between EBGP peers connected with each other directly by default.

If "ebgp-multihop" is followed by no parameter, the ttl is 255.

**Command Mode**

BGP configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage Guide**

To prevent routing loop and dampening, non-default routes that can reach the peer must exist between EBGP peers between which the BGP connection can only be established via multiple hops.

If the BGP peer group is specified, all members of the peer group adopt the settings. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

**Configuration Examples**

The following example allows establishing BGP connection between EBGP peers that are not directly connected.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 65100
Ruijie(config-router)# neighbor 10.0.0.1 ebgp-multihop
```

**Related Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.98 neighbor fall-over bfd

Use this command to enable BFD correlation with BGP. Use the **no** form or **default** form of this command to disable BFD correlation with BGP.

**neighbor** { *peer-address* | *peer-group-name* } **fall-over bfd**

**no neighbor** { *peer-address* | *peer-group-name* } **fall-over bfd**

**default neighbor** { *peer-address* | *peer-group-name* } **fall-over bfd**

**Parameter Description**

| Parameter              | Description                                             |
|------------------------|---------------------------------------------------------|
| <i>peer address</i>    | IPv4 or IPv6 address of the peer.                       |
| <i>peer-group-name</i> | Name of the peer group, containing up to 32 characters. |

**Defaults**

BFD correlation is disabled by default.

**Command**

BGP configuration mode / IPv4 VRF address family configuration mode/ IPv6 VRF address family

**Mode** configuration mode/ Scope configuration mode

**Usage** Before configuring BFD correlation, the BFD session parameters of the neighbor interface must be configured.

**Guide**

The following example enables BFD correlation to detect the forwarding path between local and the neighbor 172.16.0.2.

**Configuration Examples**

```
Ruijie(config)# router bgp 45000
Ruijie(config-router)# neighbor 172.16.0.2 remote-as 45001
Ruijie(config-router)# neighbor 172.16.0.2 fall-over bfd
```

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.99 neighbor filter-list

Use this command to enable route filtering when sending/receiving routing information to/from BGP peers. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** { *peer-address* | *peer-group-name* } **filter-list** *access-list-number* { **in** | **out** }

**no neighbor** { *peer-address* | *peer-group-name* } **filter-list** *access-list-number* { **in** | **out** }

**default neighbor** { *peer-address* | *peer-group-name* } **filter-list** *access-list-number* { **in** | **out** }

| Parameter                 | Description                                                  |
|---------------------------|--------------------------------------------------------------|
| <i>peer address</i>       | IP address of the peer, IPv4 address or IPv6 address         |
| <i>peer-group-name</i>    | Name of the peer group of up to 32 characters                |
| <i>access-list-number</i> | ACL number                                                   |
| <b>in</b>                 | Applies as-path list on the received routing information.    |
| <b>out</b>                | Applies as-path list on the distributed routing information. |

**Defaults** The function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode or BGP Scope configuration mode.

**Usage** If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If the **neighbor filter-list** command is set for a member of the peer, the setting will overwrite the setting for the group.

**Guide**

You can set different filter policies in different address-family configuration modes to control routes.

The following example enables route filtering when sending/receiving routing information to/from BGP peers.

**Configuration**

```
Ruijie(config)# ip as-path access-list 1 deny _123_
```

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 65100
Ruijie(config-router)# neighbor 10.0.0.1 filter-list 1 out
```

**Related  
Commands**

| Command                       | Description               |
|-------------------------------|---------------------------|
| <b>router bgp</b>             | Enables the BGP protocol. |
| <b>neighbor remote-as</b>     | Configures the BGP peer.  |
| <b>ip as-path access-list</b> | Creates an AS_PATH list.  |
| <b>match as-path</b>          | Matches the AS_PATH list. |

**Platform**

**Description** None

## 5.100 neighbor local-as

Use this command to configure the local AS number for the BGP peer, which could be used as its Remote AS to connect with local router. Use the **no** or **default** form of this command to restore the default setting.

**neighbor {peer-address | peer-group-name} local-as as-number [no-prepend [replace-as [dual-as]]]**

**no neighbor {peer-address | peer-group-name} local-as**

**default neighbor { peer-address | peer-group-name } local-as**

**Parameter  
Description**

| Parameter              | Description                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>peer address</i>    | IP address of the peer, IPv4 address or IPv6 address                                                                                                                                                                                  |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters                                                                                                                                                                                         |
| <i>as-number</i>       | Local AS number, in the range from 1 to 65535.<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new AS notation range is from 1 to 4294967295, represented as from 1 to 65535.65535 in dot mode. |
| <b>no-prepend</b>      | The AS-PATH of the routing information received from the peer does not depend on the Local AS. This option is disabled by default.                                                                                                    |
| <b>replace-as</b>      | The AS-PATH of the routing information sent to the peer replaces the BGP AS with the Local AS. This option is disabled by default.                                                                                                    |
| <b>dual-as</b>         | Uses BGP AS or Local AS to establish BGP connection with the device. This option is disabled by default.                                                                                                                              |

**Defaults** No Local AS is configured for the peer. If Local AS is configured, no option is configured by default. The peer could only use Local AS to establish BGP connection with local device, and adds Local AS into the AS-PATH of the received routing information, inserts Local AS to the corresponding AS-PATH before sending the routing information to the peer.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 VRF configuration mode or BGP Scope configuration mode.

**Usage Guide** Local AS could be configured on the EBGp peer only, and if the attributes of the peer change, such as EBGp converts to IBGP or union EBGp, Local AS and corresponding options will be deleted. Local AS must be different from BGP AS and this peer's Remote AS and the union ID (if federation is configured). If you have specified the BGP peer group, all members of this peer group will adopt the settings of this command. You cannot set Local AS for the specified member of the peer group separately.

**Configuration Examples** The following example configures the local AS number for the BGP peer.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 65100
Ruijie(config-router)# neighbor 10.0.0.1 local-as 23
```

|------------------|---------------------------|---------------------------|
|                  | <b>router bgp</b>         | Enables the BGP protocol. |
|                  | <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform Description** N/A

## 5.101 neighbor maximum-prefix

Use this command to limit the number of prefixes received from the specified BGP peer. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **maximum-prefix** *maximum* [*threshold*] [**warning-only**]

**no neighbor** {*peer-address* | *peer-group-name*} **maximum-prefix** *maximum*

**default neighbor** { *peer-address* | *peer-group-name* } **maximum-prefix** *maximum*

| Parameter Description | Parameter              | Description                                                                                                 |
|-----------------------|------------------------|-------------------------------------------------------------------------------------------------------------|
|                       | <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address                                                                |
|                       | <i>peer-group-name</i> | Name of the peer group of up to 32 characters                                                               |
|                       | <i>maximum</i>         | Upper limit of the number of the received route entries                                                     |
|                       | <i>threshold</i>       | Percentage of the maximum when alarming.                                                                    |
|                       | <b>warning-only</b>    | Does not terminate the BGP connection when the route entries reach the upper limit but produce a log entry. |

| <b>Defaults</b>               | This function is disabled by default.                                                                                                                                                                                                                                                                                                                                                                        |         |             |                   |                           |                           |                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-------------|-------------------|---------------------------|---------------------------|--------------------------|
| <b>Command Mode</b>           | BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode or BGP Scope configuration mode.                                                                                                                                                                                      |         |             |                   |                           |                           |                          |
| <b>Usage Guide</b>            | <p>The BGP connection will be torn down when the received routes exceeds the upper limit by default. To prevent tearing down the connection, set the "warning-only" to control that.</p> <p>If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.</p> |         |             |                   |                           |                           |                          |
| <b>Configuration Examples</b> | <p>The following example limits the number of prefixes received from the specified BGP peer.</p> <pre>Ruijie(config)# router bgp 65000 Ruijie(config-router)# neighbor 10.0.0.1 maximum-prefix 1000</pre>                                                                                                                                                                                                    |         |             |                   |                           |                           |                          |

## 5.102 neighbor next-hop-self

Use this command to set the next-hop of the route to the local BGP speaker while specifying the routes that the BGP peer redistributes. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **next-hop-self**

**no neighbor** {*peer-address* | *peer-group-name*} **next-hop-self**

**default neighbor** { *peer-address* | *peer-group-name* } **next-hop-self**

| <b>Parameter Description</b> | Parameter              | Description                                   |
|------------------------------|------------------------|-----------------------------------------------|
|                              | <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address  |
|                              | <i>peer-group-name</i> | Name of the peer group of up to 32 characters |

|                     |                                                                                                                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>     | This function is disabled by default.                                                                                                                                                                                    |
| <b>Command Mode</b> | BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode or BGP Scope configuration mode. |
| <b>Usage</b>        | This command is mostly used in the non-full-mesh-type network, such as the Frame Relay and                                                                                                                               |

**Guide** X.25, where the BGP speakers within the same subnet cannot completely be accessed mutually. If you have specified the BGP peer group, all members of the peer group will adopt the settings of the command.

**Configuration Examples**

The following example sets the next-hop of the route to the local BGP speaker.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 next-hop-self
```

**Related Commands**

|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.103 neighbor next-hop-unchanged

Use this command to maintain the next-hop when sending routes to the peer(group). Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **next-hop-unchanged**

**no neighbor** {*peer-address* | *peer-group-name*} **next-hop-unchanged**

**default neighbor** { *peer-address* | *peer-group-name* } **next-hop-unchanged**

**Parameter Description**

| Parameter                 | Description                                                         |
|---------------------------|---------------------------------------------------------------------|
| <i>peer-address</i>       | IP address of the peer, IPv4 or IPv6 address                        |
| <i>peer-group-name</i>    | Name of the peer group of up to 32 characters                       |
| <b>next-hop-unchanged</b> | Maintains the next-hop while sending the routes to the peer(group). |

**Defaults**

The next-hop will be changed by default when routes are sent to the EBGp peer.

**Command Mode**

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP L2VPN EVPN address family configuration mode or BGP Scope Global configuration mode.

**Usage Guide**

This command is used to control to maintain the next-hop route transmitting between multi-hop EBGp peer sessions. This command cannot be configured on the route reflector. And for the client of the route reflector, if this function is enabled, the **neighbor next-hop-self** command cannot be used to change the next-hop of routes. This function is mainly applied to the cross-domain VPN. In the implementation with the Option C adopted, to reduce the complete connectivity between the PEs of the cross-domain CPN, a route reflector can be set in every autonomous domain to establish the Multihop MP-EBGP connection to implement the VPN route interaction. As the next-hop route is changed as itself while sending routes to the EBGp peer by default, PE stations of other autonomous domains will consider the final next-hop of the VPN route as the route reflector

when receiving the VPN route at last, which will result in all cross-domains VPN flow going through the reflector. However, usually this is not the optimal forwarding path, and the requirement for the forwarding performance of the RR is higher. To avoid this condition, use the **neighbor next-hop-unchanged** command in the address-family VPNv4 configuration mode to maintain the next-hop of the VPNv4 route sent to the BGP peer when establishing the cross-domain Multihop MP-EBGP connection on the router reflector.

The following example maintains the next-hop when sending routes to the peer (group).

**Configuration Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 10.1.1.1 next-hop-unchanged
```

**Description** None

## 5.104 neighbor password

When the BGP connection with the BGP peer is established, use this command to enable TCP MD5 authentication and set the password. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **password** [0 | 7 ]*string*

**no neighbor** {*peer-address* | *peer-group-name*} **password**

**default neighbor** { *peer-address* | *peer-group-name* } **password**

**Parameter Description**

| Parameter              | Description                                                           |
|------------------------|-----------------------------------------------------------------------|
| <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address                          |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters                         |
| <b>0</b>               | Displays the password with encryption.                                |
| <b>7</b>               | Displays the password without encryption.                             |
| <i>string</i>          | Password for MD5 authentication in the range from up to 80 characters |

**Defaults** The function is disabled by default

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage Guide** This command will enable MD5 authentication of the TCP. BGP peers must have the same password configured; otherwise, the neighbor relationship cannot be established. When this

command is set, the local BGP speaker will re-establish the BGP connection with the BGP peer. If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

No matter in which mode, a neighbor has only one password, not one for every address family, .

The following example enables TCP MD5 authentication and sets the password.

### Configuration Examples

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 password Red-Giant
```

### Related Commands

| Command                   | Description              |
|---------------------------|--------------------------|
| <b>router bgp</b>         | Enables the BGP protocol |
| <b>neighbor remote-as</b> | Configures the BGP peer. |

### Platform

Description None

## 5.105 neighbor peer-group (creating)

Use this command to create a BGP peer group. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** *peer-group-name* **peer-group**

**no neighbor** *peer-group-name* **peer-group**

**default neighbor** *peer-group-name* **peer-group**

| Parameter   | Parameter              | Description                                   |
|-------------|------------------------|-----------------------------------------------|
| Description | <i>peer-group-name</i> | Name of the peer group of up to 32 characters |

Defaults No BGP peer group is created.

Command Mode BGP configuration mode, BGP IPv4/IPv6 VRF configuration mode or BGP Scope configuration mode.

Usage Guide If multiple BGP peers use the same update policy, the peers can be configured in the same peer group, so as to simplify the configuration and boost operation efficiency.

### Configuration Examples

The following example creates a BGP peer group.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor Red-Giant peer-group
```

### Related Commands

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

|                                                |                                                                    |
|------------------------------------------------|--------------------------------------------------------------------|
| <b>neighbor peer-group (assigning members)</b> | Configures the specified peer as the member of the BGP peer group. |
| <b>show ip bgp peer-group</b>                  | Displays the information of the BGP peer.                          |

**Platform**

**Description** None

### 5.106 neighbor peer-group (assigning members)

Use this command to configure the specified peer as a member of the BGP peer group. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** *peer-address* **peer-group** *peer-group-name*

**no neighbor** *peer-address* **peer-group** *peer-group-name*

**default neighbor** *peer-address* **peer-group** *peer-group-name*

| Parameter              | Description                                   |
|------------------------|-----------------------------------------------|
| <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address  |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters |

**Defaults** No peer exists in the peer group.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode or BGP Scope configuration mode.

**Usage Guide** Members of the peer group can adopt all configurations of the peer. It is allowed to configure an individual member of the peer group to replace the universal configuration for the peer group, but such separate configuration does not contain the configuration information that may affect the output update. In other words, every member in the peer group will always adopt the following configurations of the peer group:  
 remote-as, update-source, local-as, reconnect-interval, times, advertisement-interval, default-originate, next-hop-self, remove-private-as, send-community, distribute-list out, filter-list out, prefix-list out, route-map out, unsuppress-map, route-reflector-client.

 Do not place neighbors of different address families in the same peer group, or place IBGP and EBGp neighbors in the same peer group.

**Configuration Examples** The following example configures the specified peer as a member of the BGP peer group.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor Red-Giant peer-group
Ruijie(config-router)# neighbor 10.0.0.1 peer-group Red-Giant
```

|                     | Command                               | Description                               |
|---------------------|---------------------------------------|-------------------------------------------|
| Related<br>Commands | <b>router bgp</b>                     | Enables the BGP protocol.                 |
|                     | <b>neighbor remote-as</b>             | Configures the BGP peer.                  |
|                     | <b>neighbor peer-group (creating)</b> | Creates the BGP peer group.               |
|                     | <b>show ip bgp peer-group</b>         | Displays the information of the BGP peer. |

**Platform**

**Description** None

## 5.107 neighbor prefix-list

Use this command to implement the routing policy based on the prefix list to receive/transmit routes from/to the BGP peer. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **prefix-list** *prefix-list-name* { **in** | **out** }

**no neighbor** {*peer-address* | *peer-group-name*} **prefix-list** *prefix-list-name* { **in** | **out** }

**default neighbor** { *peer-address* | *peer-group-name* } **prefix-list** *prefix-list-name* { **in** | **out** }

|                          | Parameter              | Description                                          |
|--------------------------|------------------------|------------------------------------------------------|
| Parameter<br>Description | <i>peer address</i>    | IP address of the peer, IPv4 or IPv6 address         |
|                          | <i>peer-group-name</i> | Name of the peer group of up to 32 characters        |
|                          | <i>prefix-lis-name</i> | Name of the prefix-list of up to 32 characters       |
|                          | <b>in</b>              | Applies the prefix list to the received routes.      |
|                          | <b>out</b>             | Applies the prefix list to the redistributed routes. |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode or BGP Scope configuration mode.

For the "in" rule or "out" rule, this command cannot be used together with the **neighbor distribute-list** command. That is, only one of them takes effect.

**Usage Guide** If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If the **neighbor prefix-list in** command is set for a member of the peer, the setting will overwrite the setting for the group.

You can set different filter policies in different address-family configuration modes to control routes.

**Configuration Examples** The following example implements the routing policy based on the prefix list to receive/transmit routes from/to the BGP peer.

```
Ruijie(config)# ip prefix-list bgp-filter deny 10.0.0.1/16
```

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 prefix-list bgp-filter in
```

| Related Commands | Command                   | Description               |
|------------------|---------------------------|---------------------------|
|                  | <b>router bgp</b>         | Enables the BGP protocol. |
|                  | <b>neighbor remote-as</b> | Configures the BGP peer.  |
|                  | <b>ip prefix-list</b>     | Creates the prefix lists. |

**Platform**  
**Description**        None

### 5.108 neighbor remote-as

Use this command to configure the BGP peer (group). Use the **no** or **default** form of this command to restore the default setting.

**neighbor** { *peer-address* | *peer-group-name* } **remote-as** *as-number*

**no neighbor** { *peer-address* | *peer-group-name* } **remote-as**

**default neighbor** { *peer-address* | *peer-group-name* } **remote-as**

| Parameter Description | Parameter              | Description                                                                                                                                                                                                                                                   |
|-----------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address                                                                                                                                                                                                                  |
|                       | <i>peer-group-name</i> | Name of the peer group of up to 32 characters                                                                                                                                                                                                                 |
|                       | <i>as-number</i>       | BGP peer (group) autonomous system number in the range from 1 to 65535<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new AS notation range is from 1 to 4294967295, represented as from 1 to 65535.65535 in dot mode. |

**Defaults**                No BGP peer is configured.

**Command Mode**        BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode or BGP Scope configuration mode.

**Usage Guide**            If you have specified the BGP peer group, all members of the peer group will inherit the settings of the command.

**Configuration Examples**        The following example configures the BGP peer (group).  

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remote-as 80
```

| Related Commands | Command           | Description               |
|------------------|-------------------|---------------------------|
|                  | <b>router bgp</b> | Enables the BGP protocol. |

**Description** None

## 5.109 neighbor remove-private-as

Use this command to delete the private AS number recorded in the AS path attribute in the route sent to the specified EBGp peer. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **remove-private-as**

**no neighbor** {*peer-address* | *peer-group-name*} **remove-private-as**

**default neighbor** { *peer-address* | *peer-group-name* } **remove-private-as**

| Parameter Description | Parameter              | Description                                   |
|-----------------------|------------------------|-----------------------------------------------|
|                       | <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address  |
|                       | <i>peer-group-name</i> | Name of the peer group of up to 32 characters |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 address family configuration mode, or BGP IPv4 VRF configuration mode.

This command takes effect only on EBGp peers.

**Usage Guide** If the AS path contains the private AS number that is the AS number of the EBGp peer to be sent, the AS number is not deleted.

Private AS number range: 64512 - 65535

**Configuration Examples** The following example deletes the private AS number recorded in the AS path attribute in the route sent to the specified EBGp peer

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 remove-private-as
```

| Related Commands | Command                   | Description               |
|------------------|---------------------------|---------------------------|
|                  | <b>router bgp</b>         | Enables the BGP protocol. |
|                  | <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.110 neighbor route-map

Use this command to enable route match for the received/sent routes. Use the **no** or **default** form of this command to disable this function.

**neighbor** { *peer-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

**no neighbor** { *peer-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

**default neighbor** { *peer-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

|                          | Parameter              | Description                                   |
|--------------------------|------------------------|-----------------------------------------------|
| Parameter<br>Description | <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address  |
|                          | <i>peer-group-name</i> | Name of the peer group of up to 32 characters |
|                          | <i>map-tag</i>         | Name of the match rule                        |
|                          | <b>in</b>              | Applies the rule to the incoming routes.      |
|                          | <b>out</b>             | Applies the rule to the outgoing routes.      |

**Defaults** N/A

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode or BGP Scope configuration mode.

**Usage Guide** This command can be used to filter the incoming and outgoing routes for different neighbors by using different incoming/outgoing rules, purifying and controlling routes.  
You can set different filter policies in different address-family configuration modes to control routes.

**Configuration Examples** The following example enables route match for the received/sent routes.

```
Ruijie(config-router)# neighbor 10.0.0.1 route-map map-tag in
```

|                     | Command                                      | Description                                            |
|---------------------|----------------------------------------------|--------------------------------------------------------|
| Related<br>Commands | <b>neighbor soft-reconfiguration inbound</b> | Stores the routing information sent from the BGP peer. |
|                     | <b>show ip bgp</b>                           | Displays the BGP route entry.                          |

**Platform Description** None

## 5.111 neighbor route-reflector-client

Use this command to configure the local device as the route reflector and specifies its client. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** *peer-address* **route-reflector-client**

**no neighbor** *peer-address* **route-reflector-client**

**default neighbor** { *peer-address* | *peer-group-name* } **route-reflector-client**

| Parameter   | Parameter              | Description                                             |
|-------------|------------------------|---------------------------------------------------------|
| Description | <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address            |
|             | <i>peer-group-name</i> | Name of the peer. The name cannot exceed 32 characters. |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode or BGP Scope configuration mode.

**Usage** By default, all IBGP speakers in the autonomous system must establish neighbor relationship with each other. The BGP speaker does not forward the routes learned from an IBGP peer to other IBGP peers to avoid route loop.

**Guide** This command can be used to set route reflector, so that there is no need for all IBGP speakers to establish full neighboring relationship between each other. This will allow the route reflector to forward learned IBGP routes to other IBGP peers.

**Configuration Examples** The following example configures the local device as the route reflector and specifies its client.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 route-reflector-client
```

| Command                                | Description                                        |
|----------------------------------------|----------------------------------------------------|
| <b>router bgp</b>                      | Enables the BGP protocol.                          |
| <b>neighbor remote-as</b>              | Configures the BGP peer.                           |
| <b>bgp cluster-id</b>                  | Configures the cluster ID of the route reflectors. |
| <b>bgp client-to-client reflection</b> | Enables the route reflection between clients       |

**Platform**

**Description** None

## 5.112 neighbor send-community

Use this command to transmit community attributes to the specified BGP neighbor. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **send-community** [**both** | **standard** | **extended**]

**no neighbor** {*peer-address* | *peer-group-name*} **send-community** [**both** | **standard** | **extended**]

**default neighbor** { *peer-address* | *peer-group-name* } **send-community** [ **both** | **standard** | **extended** ]

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |                        |                                                   |
|--------------------|------------------------|---------------------------------------------------|
| <b>Description</b> | <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address      |
|                    | <i>peer-group-name</i> | Name of the peer group of up to 32 characters     |
|                    | <b>both</b>            | Transmits both standard and extended communities. |
|                    | <b>standard</b>        | Transmits the standard community only.            |
|                    | <b>extended</b>        | Transmits the extended community only.            |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4 Unicast VRF address family configuration mode, BGP IPv6 Unicast/VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode, BGP scope configuration mode

**Usage**

**Guide** This command transmits the community to the neighbor or neighbor group.

**Configuration Examples** The following example transmits community attributes to the specified BGP neighbor.

```
Ruijie(config-router)# neighbor 10.1.1.1 send-community both
```

|                         | Command                   | Description                 |
|-------------------------|---------------------------|-----------------------------|
| <b>Related Commands</b> | <b>router bgp</b>         | Enables the BGP protocol.   |
|                         | <b>neighbor remote-as</b> | Configures the BGP peer.    |
|                         | <b>ip community-list</b>  | Creates the community list. |

**Platform**

**Description** None

## 5.113 neighbor shutdown

Use this command to disconnect the BGP connection established with the specified BGP peer. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **shutdown**

**no neighbor** {*peer-address* | *peer-group-name*} **shutdown**

**default neighbor** { *peer-address* | *peer-group-name* } **shutdown**

|                              | Parameter              | Description                                   |
|------------------------------|------------------------|-----------------------------------------------|
| <b>Parameter Description</b> | <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address  |
|                              | <i>peer-group-name</i> | Name of the peer group of up to 32 characters |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

This command is used to disconnect valid connection established with the specified peer (group), and delete all associated routing information. However, this command still keeps the configuration information of that specified peer (group).

**Usage****Guide**

If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

**Configuration**

The following example disconnects the BGP connection established with the specified BGP peer.

**Examples**

```
Ruijie(config)# router bgp 60
Ruijie(config-router)# neighbor 10.0.0.1 shutdown
```

**Related****Commands**

| Command                    | Description                         |
|----------------------------|-------------------------------------|
| <b>router bgp</b>          | Enables the BGP protocol.           |
| <b>neighbor remote-as</b>  | Configures the BGP peer.            |
| <b>show ip bgp summary</b> | Displays the BGP connection status. |

**Platform****Description**

None

## 5.114 neighbor soft-reconfiguration inbound

Use this command to store the routing information sent from the BGP peer. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **soft-reconfiguration inbound**

**no neighbor** {*peer-address* | *peer-group-name*} **soft-reconfiguration inbound**

**default neighbor** { *peer-address* | *peer-group-name* } **soft-reconfiguration inbound**

**Parameter****Description**

| Parameter              | Description                                   |
|------------------------|-----------------------------------------------|
| <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address  |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters |

**Defaults**

This function is disabled by default.

**Command****Mode**

BGP configuration mode, BGP IPv4 Unicast VRF address family configuration mode, BGP IPv6 Unicast/VRF address family configuration mode, BGP VPNv4/VPNv6 address family configuration mode, BGP scope configuration mode

This command restarts the BGP session, and keeps the unchanged routing information sent from the BGP peer (group).

**Usage**

Executing this command will consume more memories. If both parties support the route refresh function, this command becomes unnecessary. You may run the **show ip bgp neighbors** command to judge whether the peer can support the route refresh function.

**Guide**

If the BGP peer group is specified, all members of the peer group adopt the settings of this

command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

### Configuration Examples

The following example stores the routing information sent from the BGP peer.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 soft-reconfiguration inbound
```

### Related Commands

| Command                      | Description                               |
|------------------------------|-------------------------------------------|
| <b>router bgp</b>            | Enables the BGP protocol.                 |
| <b>neighbor remote-as</b>    | Configures the BGP peer.                  |
| <b>show ip bgp neighbors</b> | Displays the information of the BGP peer. |
| <b>clear ip bgp</b>          | Resets the BGP peer session.              |

### Platform

**Description** None

## 5.115 neighbor timers

In specifying BGP peer to establish the BGP connection, use this command to set the keepalive and holdtime time values used for establishing the BGP connection. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **timers** *keepalive holdtime [minimum-holdtime]* | **connect connect-retry** }

**no neighbor** [*peer-address* | *peer-group-name*] **timers** [ **connect** ]

**default neighbor** { *peer-address* | *peer-group-name* } **timers** [ **connect** ]

### Parameter Description

| Parameter               | Description                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>peer-address</i>     | IP address of the peer, IPv4 or IPv6 address                                                                                           |
| <i>peer-group-name</i>  | Name of the peer group of up to 32 characters                                                                                          |
| <i>keepalive</i>        | Time interval to send the KEEPALIVE message to the BGP peer.<br>Range: 0-65535 seconds                                                 |
| <i>holdtime</i>         | Time interval to consider the BGP peer alive<br>Range: 0-65535 seconds                                                                 |
| <i>minimum-holdtime</i> | Allows a minimum holdtime value of neighbor advertisement. It is unrestricted when the value is 0.<br>The range is 0 to 65535 seconds. |
| <i>connect-retry</i>    | The value of the connect-retry timer is 15s.                                                                                           |

### Defaults

*keepalive*: 60 seconds  
*holdtime*: 180 seconds  
*minimum-holdtime*: 0 seconds  
connect-retry: 15 seconds

**Command** BGP configuration mode, BGP IPv4 VRF address family configuration mode, BGP IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Mode**

A proper keepalive value must not exceed one-third of the holdtime value.

If the time is configured for an individual peer or a peer group, that peer or peer-group will use its time to replace the global time configuration and connect the peer.

**Usage**

**Guide** If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

**Configuration** The following example sets the keepalive and holdtime time values used for establishing the BGP connection.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 80 240
```

The following example sets the connect-retry time values used for establishing the BGP connection.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 timers connect 100
```

**Related Commands**

| Command           | Description                                      |
|-------------------|--------------------------------------------------|
| <b>router bgp</b> | Enables the BGP protocol.                        |
| <b>timers bgp</b> | Sets the keepalive and holdtime values globally. |

**Platform**

**Description** None

## 5.116 neighbor unsuppress-map

Use this command to selectively advertise routing information suppressed by aggregate-address command. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** {*peer-address* | *peer-group-name*} **unsuppress-map** *map-tag*

**no neighbor** {*peer-address* | *peer-group-name*} **unsuppress-map** *map-tag*

**default neighbor** { *peer-address* | *peer-group-name* } **unsuppress-map** *map-tag*

**Parameter Description**

| Parameter              | Description                                   |
|------------------------|-----------------------------------------------|
| <i>peer-address</i>    | IP address of the peer                        |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters |
| <i>map-tag</i>         | Name of the route-map of up to 32 characters  |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4 Unicast/VRF address family configuration mode, BGP IPv6 Unicast/VRF address family configuration mode, BGP L2VPN EVPN address family configuration mode BGP VPNv4/VPNv6 address family configuration mode, BGP scope configuration mode

This command advertises the specified suppressed routes.

**Usage Guide** If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

The following example selectively advertises routing information suppressed by aggregate-address command.

**Configuration Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 unsuppress-map
unspress-route
```

**Related Commands**

| Command                   | Description                       |
|---------------------------|-----------------------------------|
| <b>router bgp</b>         | Enables the BGP protocol.         |
| <b>neighbor remote-as</b> | Configures the BGP peer.          |
| <b>aggregate-address</b>  | Configures the aggregate address. |
| <b>route-map</b>          | Configures the route-map          |

**Platform**

**Description** None

## 5.117 neighbor update-delay

Use this command to configure the time of BGP delayed advertisement for first routes. Use the **no** or **restore** form of the command to restore the default setting.

**neighbor** { *peer-address* | *peer-group-name* } **update-delay** *time*

**no neighbor** { *peer-address* | *peer-group-name* } **update-delay**

**default neighbor** { *peer-address* | *peer-group-name* } **update-delay**

**Parameter Description**

| Parameter              | Description                                         |
|------------------------|-----------------------------------------------------|
| <i>peer-address</i>    | IP address of the peer, IPv4 or IPv6 address        |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters       |
| <i>time</i>            | Time of BGP delayed advertisement for first routes. |

**Defaults** The function is disabled by default.

**Command Mode** BGP configuration mode/ BGP IPv4 VRF address family configuration mode/ BGP IPv6 VRF address family configuration mode/ BGP scope configuration mode

After BGP starts, BGP peers negotiate to establish the neighborhood before sending route information (update packets).

**Usage**

In addition, after **update-delay** is configured on the local end, a specific neighbor sends route

**Guide**

information to the local end, the local end will send out the route information after the delay time.

If the BGP peer group is specified, all members of the peer group adopt the settings of this command.

**Configuration**

The following example sets the delayed time to 60s.

**Examples**

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 update-delay 60
```

**Platform****Description**

N/A

## 5.118 neighbor update-source

Use this command to configure the interface for BGP connection of the IBGP peer..

**neighbor** { *peer-address* | *peer-group-name* } **update-source** {interface-type interface-number | address }

Use the **no** form of the command to remove the source address configuration for the BGP peer.

**no neighbor** {*peer-address* | *peer-group-name*} **update-source**

Use the **default** form of the command to restore the default settings.

**default neighbor** { *peer-address* | *peer-group-name* } **update-source**

**Parameter****Description**

| Parameter                                        | Description                                                                                                                        |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>peer-address</i>                              | IP address of the peer, IPv4 or IPv6 address                                                                                       |
| <i>peer-group-name</i>                           | Name of the peer group of up to 32 characters                                                                                      |
| <i>interface-type</i><br><i>interface-number</i> | Interface name                                                                                                                     |
| <i>address</i>                                   | The interface address which is used for BGP connection. The address type ( IPv4 or IPv6) must be same as that of the peer address. |

**Defaults**

The local interface is used as the egress interface by default.

**Command****Mode**

BGP configuration mode/ IPv4 VRF address family configuration mode/ IPv6 VRF address family configuration mode/ Scope configuration mode

**Usage**

You can use this command to enable the loopback interface to establish a BGP connection with the

**Guide**

peer.

The interface address specified for BGP connection must be valid in local, otherwise the BGP connection may be faulty.

All members in a BGP peer group inherit the settings of this command. Particularly, if the interface address is used, only the member whose address type is same as the interface address's can inherit the settings of this command.

If the IPv6 address of the loopback interface is used for neighbor connection, both peers need to be configured with the loopback interface. The BGP connection can be established only when the address of the egress interface on the peer is same as that of the neighbor in local.

A loopback interface address can be configured on different interfaces. You need to specify only the interface name,

The peer configured with the IPv6 address of loopback interface support only one-hop BGP neighbor connection.

**Configuration Examples**

The following example establishes the BGP connection.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# neighbor 10.0.0.1 update-source loopback 1
```

**Related Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform**

**Description** None

## 5.119 neighbor version

Use this command to display the number of the BGP protocol version used by the specific BGP neighbor. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** { *peer-address* | *peer-group-name* } **version** 4

**no neighbor** { *peer-address* | *peer-group-name* } **version**

**default neighbor** { *peer-address* | *peer-group-name* } **version**

| Parameter              | Description                                   |
|------------------------|-----------------------------------------------|
| <i>peer-address</i>    | IP address of the peer                        |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters |
| 4                      | Version number                                |

**Defaults** The default version number is 4.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode

**Usage****Guide**

When the command is used, BGP will lose the version negotiation function.

**Configuration**

The following example displays the number of the BGP protocol version used by the specific BGP neighbor.

**Examples**

```
Ruijie(config-router)# neighbor 10.1.1.1 version 4
```

**Related****Commands**

| Command                   | Description               |
|---------------------------|---------------------------|
| <b>router bgp</b>         | Enables the BGP protocol. |
| <b>neighbor remote-as</b> | Configures the BGP peer.  |

**Platform****Description**

None

## 5.120 neighbor weight

Use this command to set the weight for the specific neighbor. Use the **no** or **default** form of this command to restore the default setting.

**neighbor** { *peer-address* | *peer-group-name* } **weight** *number*

**no neighbor** { *peer-address* | *peer-group-name* } **weight**

**default neighbor** { *peer-address* | *peer-group-name* } **weight**

**Parameter****Description**

| Parameter              | Description                                   |
|------------------------|-----------------------------------------------|
| <i>peer-address</i>    | IP address of the peer                        |
| <i>peer-group-name</i> | Name of the peer group of up to 32 characters |
| <i>number</i>          | Weight, in the range from 0 to 65535.         |

**Defaults**

No weight is configured for the specific neighbor by default. In this case, the learned route weight is 0 and the locally generated route's weight is 32768 initially.

**Command****Mode**

BGP configuration mode, BGP IPv4 Unicast/VRF address family configuration mode, BGP IPv6 Unicast/VRF address family configuration mode, BGP scope configuration mode and BGP L2VPN EVPN family address configuration mode

**Usage****Guide**

When the command is used, routes learnt from the neighbor use this value as the initial weight value. The higher the weight, the higher the priority is.

Executing the **set weight** command in the route map of the neighbor will overwrite this value.

**Configuration****Examples**

The following example sets the weight for the specific neighbor.

```
Ruijie(config-router)# neighbor 10.1.1.1 weight 73
```

**Related**

**Platform**

**Description** None

## 5.121 network

Use this command to configure the network information to be advertised by the local BGP speaker. Use the **no** or **default** form of this command to restore the default setting.

**network** *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor**]

**no network** *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor**]

**default network** *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor** ]

| <b>Parameter</b><br><b>Description</b> | <b>Parameter</b>      | <b>Description</b>                           |
|----------------------------------------|-----------------------|----------------------------------------------|
|                                        | <i>network-number</i> | Network number                               |
|                                        | <i>mask</i>           | Subnet mask                                  |
|                                        | <i>map-tag</i>        | Name of the route-map of up to 32 characters |
|                                        | <b>backdoor</b>       | The route is a backdoor route.               |

**Defaults** No network information is specified by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage Guide** This command allows injecting the IGP route into the BGP routing table. The network information advertised can be direct route, static route and dynamic route. The "route-map" can be used to modify the network information.

**Configuration Examples** The following example configures the network information to be advertised by the local BGP speaker.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# network 10.0.0.1 mask 255.255.0.0
```

| <b>Related Commands</b> | <b>Command</b>                 | <b>Description</b>                   |
|-------------------------|--------------------------------|--------------------------------------|
|                         | <b>router bgp</b>              | Enables the BGP protocol.            |
|                         | <b>redistribute</b>            | Configures the route redistribution. |
|                         | <b>Network synchronization</b> | Enables network synchronization.     |

**Platform**

**Description** None

## 5.122 network synchronization

Use this command to advertise the network information after the local BGP speaker is synchronized with the local device. Use the **no** or **default** form of this command to directly advertise the network information.

**network synchronization**

**no network synchronization**

**default network synchronization**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage Guide** This command is used to modify the status of the network during the process of advertisement. It is not recommended to turn off this switch lest route black hole is caused.

**Configuration Examples** The following example advertises the network information after the local BGP speaker is synchronized with the local device.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# network synchronization
```

| Related Commands | Command             | Description                             |

|                  | <b>network(BGP)</b> | Configures the route to be distributed. |

**Platform**

**Description** None

## 5.123 overflow memory-lack

Use this command to allow BGP to enter the OVERFLOW state when the memory is insufficient. Use the **no** or **default** form of this command to disable this function.

**overflow memory-lack**

**no overflow memory-lack**

**default overflow memory-lack**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** Allow the BGP to enter the OVERFLOW state when the memory is insufficient.

### Command

**Mode** BGP configuration mode or BGP Scope Global configuration mode

In the BGP OVERFLOW state, the newly-learned routes are discarded, which prevents the memory from increasing.

When this function is enabled, if the BGP address family is in the OVERFLOW state, the newly-learned routes will be discarded, which may result in network loop. To prevent this, BGP generates a default route directing to the NULL interface, and the default route will always exist in the OVERFLOW state.

### Usage

**Guide** Use the **clear bgp {addressfamily|all} \*** command to reset the BGP and clear the OVERFLOW state in the BGP address family.

Use the no option to disallow the BGP to enter the OVERFLOW state when the memory is insufficient, which may lead to the continuous exhaustion of the memory resources. When the memory has been exhausted to a certain degree, BGP will break down all neighbors and delete all learned routes.

### Configuration

The following example sets BGP not to enter the OVERFLOW configuration status when the memory is insufficient.

### Examples

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# no overflow memory-lack
```

## 5.124 rd

Use this command to configure a RD value for the EVI instance. Use the **no** or **restore** form of this command to restore the default settings.

```
rd { auto | rd_value }
```

```
no rd { auto | rd_value }
```

```
default rd
```

|--------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <b>auto</b>     | Generates the RD value automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                    | <i>rd_value</i> | <p>Indicates value of the RD.</p> <p>There are 3 forms of <i>rd_value</i>:</p> <ol style="list-style-type: none"> <li><i>rd_value</i> = <i>as_num</i>:<i>nn</i><br/>The <i>as_num</i> indicates the public AS number (2 bytes) and <i>nn</i> is customized. The range is from 0 to 4,294,967,295.</li> <li><i>rd_value</i> = <i>ip_addr</i>:<i>nn</i><br/>The <i>ip_add</i> refers to the global IP address and <i>nn</i> is customized. The range is from 0 to 65,535.</li> <li><i>rd_value</i> = <i>as4_num</i>:<i>nn</i><br/>The <i>as4_num</i> indicates the public AS number (2 bytes) and <i>nn</i> is customized. The range is from 0 to 65,535.<br/>The 4-byte AS notation range is from 1 to 4,294,967,295, represented as from 1 to 65535.65535 in dot mode.</li> </ol> |

**Defaults** The RD value is not configured by default.

**Command**

**Mode** evpn-vni configuration mode

If an EVI is configured with a RD value, the RD value cannot be revised. If you want to revise it, you can only delete the EVI first and then configure a new RD value for it. One EVI can be configured with one RD value only.

**Usage Guide**

 The RD format in 4-byte AS is **AS4:NN**. The **AS4** supports demical and dot mode. The range of **AS4** is from 1 to 4,294,967,295, represented as from 1 to 65535.65535 in dot mode. The range of **NN** is from 1 to 65,535.

 For AS number in the range of 1 to 65,535, it will be saved in the format of 2-byte AS, because under this condition, the demical and dot mode AS are the same.

The following example sets RD for EVI 100. The value is 100 : 1.

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 100
Ruijie(config-evpn-vni)# rd 100:1
```

**Configuration Examples**

The following example sets RD for EVI 200. The value is auto.

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 200
Ruijie(config-evpn-vni)# rd auto
```

**Platform**

**Description** N/A

## 5.125 redistribute

Use this to redistribute routes between the other routing protocol and the BGP. Use the **no** or **default** form of this command to restore the default setting.

**redistribute** *protocol-type* [**route-map** *map-tag*] [**metric** *metric-value*]

**no redistribute** *protocol-type* [**route-map** *map-tag*] [**metric**]

**default redistribute protocol-type** [ **route-map** *map-tag* ] [ **metric** ]

**Parameter Description**

| Parameter                         | Description                                                                           |
|-----------------------------------|---------------------------------------------------------------------------------------|
| <i>protocol-type</i>              | The source protocol types for redistributing routes, including connected, static, RIP |
| <b>route-map</b> <i>map-tag</i>   | Specifies the route map.<br>No route map is associated with by default.               |
| <b>metric</b> <i>metric-value</i> | Sets the default metric of the routes to be redistributed, null by default.           |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

When a switch supports multiple routing protocols, the coordination between these protocols becomes an important task. The switch may run multiple routing protocols at the same time, so it should redistribute a protocol's information to another protocol. This is applicable to all IP routing protocols.

**Usage Guide**

-  When you configure the **no** form of this command with parameters, the corresponding parameter configuration will be removed. The no form removes redistribution without any parameters configured.
-  The route metric generated by the route-map command takes precedence over the one generated by the metric option of this command. If both are unavailable, the redistributed one is used.

**Configuration Examples**

The following example redistributes routes between the other routing protocol and the BGP.

```
Ruijie(config-router)# redistribute static route-map static-rmap
```

**Related Commands**

|-------------------------|--------------------------------------|
| <b>show ip protocol</b> | Displays the protocol configuration. |

**Platform Description**

None

## 5.126 redistribute ospf

Use this command to redistribute routes between OSPF and BGP. Use the **no** or **default** form of this command to restore the default setting.

**redistribute ospf** *process-id* [**route-map** *map-tag*] [**metric** *metric-value*] [**match internal external** [1|2] **nssa-external** [1|2]]

**no redistribute ospf** *process-id* [**route-map** *map-tag*] [**metric** *metric-value*] [**match internal external** [1|2] **nssa-external** [1|2]]

**default redistribute ospf** *process-id* [ **route-map** *map-tag* ] [ **metric** ] [ **match** { **internal** | **external** [ 1 | 2 ] } | **nssa-external** [ 1 | 2 ] }

**Parameter Description**

| Parameter                         | Description                                                                                                                  |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <i>process-id</i>                 | OSPF process ID to be redistributed                                                                                          |
| <b>route-map</b> <i>map-tag</i>   | Specifies the route map.<br>No route map is associated by default.                                                           |
| <b>metric</b> <i>metric-value</i> | Sets the default metric of the routes to be redistributed, null by default.                                                  |
| <b>match</b>                      | Matches the sub type of OSPF routes.                                                                                         |
| <b>internal</b>                   | Matches the internal OSPF routes, the default configuration.                                                                 |
| <b>external</b> [ 1   2 ]         | Matches the external OSPF routes. You can specify the concrete type (v1 or v2) or v1 and v2 without indication.              |
| <b>nssa-external</b> [ 1   2 ]    | Matches the NSSA-external type of OSPF routes. You can specify the concrete type (v1 or v2) or v1 and v2 without indication. |

**Defaults** This function is disabled by default.

**Command Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

When a switch supports multiple routing protocols, the coordination between these protocols becomes an important task. The switch may run multiple routing protocols at the same time, so it should redistribute a protocol's information to another protocol.

**Usage Guide**

 When you configure the **no** form of this command with parameters, the corresponding parameter configuration will be removed. The **no** form removes redistribution without any parameters configured.

 The filtering rule of OSPF routing: filtering the OSPF routing type according to the configured match option before filtering the route-map rule. The route metric generated by the **route-map** command takes precedence over the one generated by the metric option of this command. If both are not available, the redistributed one is used.

**Configuration** The following example redistributes routes between OSPF and BGP.

**Examples**

```
Ruijie(config-router)# redistribute ospf 2 route-map static-rmap
```

## 5.127 redistribute isis

Use this command to redistribute routes between ISIS and BGP. Use the **no** or **default** form of this command to restore the default settings.

**redistribute isis** [*isis-tag*] [**route-map** *map-tag*] [**metric** *metric-value*] [**level-1** | **level-1-2** | **level-2**]

**no redistribute isis** [*isis-tag*] [**route-map** *map-tag*] [**metric**] [**level-1** | **level-1-2** | **level-2**]

**default redistribute isis** [*isis-tag*] [**route-map** *map-tag*] [**metric**] [**level-1** | **level-1-2** | **level-2**]

**Parameter  
Description**

| Parameter                         | Description                                                                 |
|-----------------------------------|-----------------------------------------------------------------------------|
| <i>isis-tag</i>                   | (Optional)ISIS process ID to be redistributed                               |
| <b>route-map</b> <i>map-tag</i>   | Specifies the route map.<br>No route map is associated by default.          |
| <b>metric</b> <i>metric-value</i> | Sets the default metric of the routes to be redistributed, null by default. |
| <b>level-1</b>                    | Redistributes level-1 ISIS routes.                                          |
| <b>level-1-2</b>                  | Redistributes level-1 and level-2 ISIS routes.                              |
| <b>level-2</b>                    | Redistributes level-2 ISIS routes.                                          |

**Defaults**

This function is disabled by default.

**Command  
Mode**

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage  
Guide**

When a switch supports multiple routing protocols, the coordination between these protocols becomes an important task. The switch may run multiple routing protocols at the same time, so it should redistribute a protocol's information to another protocol. This is applicable to all IP routing protocols.

When you configure the **no** form of this command with parameters, the corresponding parameter configuration will be removed. The **no** form removes redistribution without any parameters configured.

The filtering rule of ISIS routing is: filtering the ISIS routing type according to the configured level option before filtering the route-map rule. The route metric generated by the route-map command takes precedence over the one generated by the metric option of this command. If both are unavailable, the redistributed one is used.

**Configuration** The following example redistributes routes between ISIS and BGP.

**Examples**

```
Ruijie(config-router)# redistribute isis route-map static-rmap
```

## 5.128 route-target

Use this command to configure a RT (Route Target) for EVI. Use the **no** or **restore** form of this command to restore the default settings.

**route-target** { import | export | both } { auto | *rt\_value* }

**no route-target** { import | export | both } { auto | *rt\_value* }

**default route-target** { import | export | both } { auto | *rt\_value* }

| Parameter          | Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <b>auto</b>     | Generates the RD value automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                    | <b>import</b>   | Sets the import RT value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                    | <b>export</b>   | Sets the export RT value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                    | <b>both</b>     | Sets the import and export RT value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                    | <i>rt_value</i> | <p>Indicates value of the RT.</p> <p>There are 3 forms of <i>rt_value</i>:</p> <ol style="list-style-type: none"> <li><i>rt_value</i> = as_num:nn<br/>The as_num indicates the public AS number (2 bytes) and nn is customized. The range is from 0 to 4,294,967,295.</li> <li><i>rt_value</i> = ip_addr:nn<br/>The ip_add refers to the global IP address and nn is customized. The range is from 0 to 65,535.</li> <li><i>rt_value</i> = as4_num:nn<br/>The as4_num indicates the public AS number (2 bytes) and nn is customized. The range is from 0 to 65,535.</li> </ol> <p>The 4-byte AS notation range is from 1 to 4,294,967,295, represented as from 1 to 65535.65535 in dot mode.</p> |

**Defaults** The RT value is not configured by default.

**Command**

**Mode** evpn-vni configuration mode

**Usage** One EVI can be configured with multiple import and export RT values.

**Guide**

- i The format of auto RT is **AS2:NN**. The **AS2** is the AS number of 2B. If an AS number of 4B is configured, it will be split into two 2B AS number and then be put in the RT. The **nn** indicates value of **vni-id** and has a space of 4B.
- i If the AS number of BGP changes, the auto RT will be changed, too.
- i If the manually configured RT is coherent with the auto RT, both will be displayed. After the **auto** command is configured and the automatically generated RT value is 100 : 1, then if you delete value 100 : 1, only the value not the **auto** command will be deleted.

The following example sets RT for EVI 100. The values are import RT 100:1, 100:4, export RT 100:2, 100:4, and both auto.

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 100
Ruijie(config-evpn-vni)# route-target import 100:1
Ruijie(config-evpn-vni)# route-target export 100:2
Ruijie(config-evpn-vni)# route-target both 100:4
Ruijie(config-evpn-vni)# route-target both auto
```

**Configuration**

**Examples**

**Platform**

**Description** N/A

## 5.129 router bgp

Use this command to enable the BGP protocol, configure the local autonomous system number and enter BGP protocol configuration mode. Use the **no** or **default** form of this command to restore the default setting.

**router bgp** *as-number*

**no router bgp** *as-number*

**default router bgp** *as-number*

**Parameter**

**Description**

| Parameter        | Description                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> | AS number in the range from 1 to 65535<br>In the 10.4(3) or later versions, the 4-byte AS notation is supported, namely, the new AS notation range is from 1 to 4294967295, represented as from 1 to 65535.65535 in dot mode. |

**Defaults**

This function is disabled by default.

**Command**

**Mode**

Global configuration mode

**Usage**

This command is used to start the BGP protocol.

**Guide** RFC4839 defines a new reserved AS notation 23456, which cannot be used. The original private AS notation in the range from 64512 to 65534 is still effective, 65535 is reserved for special purposes.

RFC 5398 also defines two groups of new reserved AS notation for documents, whose ranges are from 64496 to 64511 and from 65536 to 65551.

**Configuration** The following example enables the BGP protocol.

**Examples** Ruijie(config)# router bgp 65000

**Related  
Commands**

| Command              | Description                                                             |
|----------------------|-------------------------------------------------------------------------|
| <b>ip routing</b>    | Enables IP routing.                                                     |
| <b>bgp router-id</b> | Sets the ID of the device running the BGP protocol                      |
| <b>network</b>       | Sets the network information to be advertised by the local BGP speaker. |

**Platform**

**Description** None

## 5.130 synchronization

Use this command to enable the synchronization mechanism of BGP and IGP routing information. Use the **no** or **default** form of this command to restore the default settings.

**synchronization**

**no synchronization**

**default synchronization**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command  
Mode** BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

The synchronization between BGP and IGP aims to prevent the possible route black hole. In any of the two cases below, you may cancel the synchronization mechanism to ensure fast convergence of routing information.

**Usage  
Guide**

- There is no route information which passes through this AS (In general, this AS is an end AS).
- All devices within this AS operate BGP protocol and the full connection relationship is established among all BGP Speakers (The adjacent relationship is established between any two BGP Speakers).

**Configuration** The following example enables the synchronization mechanism of BGP and IGP routing

**Examples**

information.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# synchronization
```

**Related****Commands**

| Command           | Description               |
|-------------------|---------------------------|
| <b>router bgp</b> | Enables the BGP protocol. |

**Platform****Description**

None

## 5.131 table-map

Use this command to control the route information distributed to the kernel table. Use the **no** or **default** form of this command to restore the default setting.

**table-map** *route-map-name*

**no table-map**

**default table-map**

**Parameter****Description**

| Parameter             | Description           |
|-----------------------|-----------------------|
| <i>route-map-name</i> | Name of the route-map |

**Defaults**

No table-map is configured by default.

**Command****Mode**

BGP configuration mode, BGP IPv4/IPv6 Unicast address family configuration mode, BGP IPv4/IPv6 VRF address family configuration mode or BGP Scope configuration mode.

**Usage****Guide**

BGP uses the table-map to control the information distributed to the kernel routing table. The table-map is used to modify attributes of that route information, and it only takes effect on the IPv4 address-family.

**Configuration****Examples**

The following example controls the route information distributed to the kernel table.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# table-map bgp_tm
```

**Related****Commands**

| Command          | Description              |
|------------------|--------------------------|
| <b>route-map</b> | Configures the route-map |

**Platform****Description**

None

## 5.132 timers bgp

Use this command to adjust the BGP network timer. Use the **no** or **default** form of this command to restore the default value.

**timers bgp** *keepalive holdtime* [*minimum-holdtime*]

**no timers bgp**

**default timers bgp**

| Parameter               | Description                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>keepalive</i>        | Time interval to send the keepalive message to the BGP peer<br>Range: 0-65535 seconds.                                                 |
| <i>holdtime</i>         | Time interval to consider the BGP peer alive<br>Range: 0-65535 seconds.                                                                |
| <i>Minimum-holdtime</i> | Allows a minimum holdtime value of neighbor advertisement. It is unrestricted when the value is 0.<br>The range is 0 to 65535 seconds. |

**Defaults**  
*keepalive*: 60 seconds  
*holdtime*: 180 seconds  
*minum-holdtime*: 0 seconds

**Command**

**Mode** BGP configuration mode / BGP scope global configuration mode

A proper keepalive value must not exceed one-third of the holdtime value.

**Usage** If the time is configured for an individual peer or a peer group, that peer or peer-group will use its time to replace the global time configuration and connect the peer.

**Guide** If the BGP peer group is specified, all members of the peer group adopt the settings of this command. If this command is set for a member of the peer, the setting will overwrite the setting for the group.

**Configuration Examples** The following example adjusts the BGP network timer.

```
Ruijie(config)# router bgp 65000
Ruijie(config-router)# timers bgp 80 240
```

| Related Commands | Command                | Description                                                       |
|------------------|------------------------|-------------------------------------------------------------------|
|                  | <b>neighbor timers</b> | Sets the keepalive and holdtime values on the basis of neighbors. |

**Platform**

**Description** None

### 5.133 show bgp all

Use this command to display all the address-families information of BGP route. The use of this command is consistent with other BGP's show commands.

Display the parameters of the route information.

```
show bgp all [ community [ community-number [ exact-match ] ] | filter-list path-list-number |
community-list community-name [ exact-match ] | extcommunity-list extcommunity-name | regexp
regexp | quote-regexp regexp | inconsistent-as ]
```

Display the route dampening parameter.

```
show bgp all dampening { flap-statistics | dampened-paths | parameters }
```

Display the related information of the neighbors.

```
show bgp all neighbors [ peer-address [ received-routes | routes | advertised-routes | policy
[ detail ] ] ]
```

```
show bgp all summary
```

Display the update-group information.

```
show bgp [ instance as-num ] all update-group [ neighbor-address | update-group-index ]
[ summary ]
```

Parameter  
Description

| Parameter                                         | Description                                                                                                                                                                                                                                           |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>community</b> <i>community-number</i>          | Displays the routing information including the specified community value. Community-number can be in the format of AA:NN (autonomous system number / 2-byte number), or the following pre-defined value: internet, no-export, local-as, no-advertise. |
| <b>community-list</b> <i>community-name</i>       | Displays the BGP routing information matching the specified community-list.                                                                                                                                                                           |
| <b>exact-match</b>                                | Routing information exactly matching the community value or community-list.                                                                                                                                                                           |
| <b>dampening dampened-paths</b>                   | Displays the restrained routing information.                                                                                                                                                                                                          |
| <b>dampening flap-statistics</b>                  | Displays the routing dampening statistics.                                                                                                                                                                                                            |
| <b>dampening parameters</b>                       | Displays the routing dampening parameters.                                                                                                                                                                                                            |
| <b>extcommunity-list</b> <i>extcommunity-name</i> | Displays the routing information including the specified extcommunity value.                                                                                                                                                                          |
| <b>filter-list</b> <i>path-list-number</i>        | Displays the routing information matching the filter-list.                                                                                                                                                                                            |

|                                                                             |                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>inconsistent-as</b>                                                      | Displays the routing information of the inconsistent source AS.                                                                                                                                                                                 |
| <b>neighbors</b> [ <i>peer-address</i> ]                                    | Displays all the BGP neighbors' information.                                                                                                                                                                                                    |
| <b>neighbors</b> <i>peer-address</i> <b>received-routes</b>                 | Displays all routing information received from the specified peer (including the accepted and refused route).                                                                                                                                   |
| <b>neighbors</b> <i>peer-address</i> <b>routes</b>                          | Displays all the accepted routing information received from the peer.                                                                                                                                                                           |
| <b>neighbors</b> <i>peer-address</i> <b>advertised-routes</b>               | Displays all the routing information sent to the specified peer.                                                                                                                                                                                |
| <b>neighbors</b> <i>peer-address</i> <b>policy</b>                          | Displays the related routing policy information of BGP neighbors. (General)                                                                                                                                                                     |
| <b>neighbors</b> <i>peer-address</i> <b>policy detail</b>                   | Displays the related routing policy information of BGP neighbors. (Detail)                                                                                                                                                                      |
| <b>quote-regexp</b> <i>regexp</i>                                           | Displays the BGP routing information with the AS path attribute matching the specified regexp within the double quote marks.                                                                                                                    |
| <b>regexp</b> <i>regexp</i>                                                 | Displays the BGP routing information with the AS path attribute matching the specified regexp.                                                                                                                                                  |
| <b>Summary</b>                                                              | Displays BGP neighbor information.                                                                                                                                                                                                              |
| <b>update-group</b> [ <i>neighbor-address</i>   <i>update-group-index</i> ] | Display update-group information.<br>When <i>neighbor-address</i> is specified, display the update-group information of the specified neighbor.<br>When <i>update-group-index</i> is specified, display the specified update-group information. |

**Command****Mode** Privileged EXEC mode**Usage****Guide** N/A

The following example shows all neighbors' information.

```
Ruijie(config)# show bgp all
For address family: IPv4 Unicast
BGP table version is 1, local router ID is 1.2.3.4
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
                S Stale
```

**Configuration****Examples**

```
Origin codes: i - IGP, e - EGP, ? - incomplete

      Network          Next Hop          Metric      LocPrf      Weight Path
*> 1.0.0.0            0.0.0.0              0              32768      ?

Total number of prefixes 1

For address family: IPv6 Unicast

BGP table version is 1, local router ID is 1.2.3.4

Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               S Stale

Origin codes: i - IGP, e - EGP, ? - incomplete

      Network          Next Hop          Metric      LocPrf      Weight Path
*> 5750:1::/120      ::                  0              32768      ?

Total number of prefixes 1
```

| <b>show bgp ipv4 unicast</b> | Displays the IPv4 unicast route information of BGP |

**Platform**

**Description**      None

### 5.134 show bgp ipv4 unicast

Use this command to display the IPv4 unicast route information of BGP.

**show bgp ipv4 unicast** [ vrf *vrf-name* ] [ network [ *network-mask* [ **longer-prefixes** ] ] ]

**show bgp ipv4 unicast** [ vrf *vrf-name* ] **community** *community-number* [ **exact-match** ]

**show bgp ipv4 unicast** [ vrf *vrf-name* ] **community-list** *community-name* [ **exact-match** ]

**show bgp ipv4 unicast** [ vrf *vrf-name* ] **extcommunity-list** *extcommunity-name*

**show bgp ipv4 unicast** [ vrf *vrf-name* ] **dampening** **dampened-paths**

**show bgp ipv4 unicast [ vrf *vrf-name* ] dampening flap-statistics**

**show bgp ipv4 unicast [ vrf *vrf-name* ] filter-list *path-list-number***

**show bgp ipv4 unicast [ vrf *vrf-name* ] inconsistent-as**

**show bgp ipv4 unicast [ vrf *vrf-name* ] prefix-list *ip-prefix-list-name***

**show bgp ipv4 unicast [ vrf *vrf-name* ] quote-regexp *regexp***

**show bgp ipv4 unicast [ vrf *vrf-name* ] regexp *regexp***

**show bgp ipv4 unicast[ vrf *vrf-name* ] route-map *map-tag***

**show bgp ipv4 unicast [ vrf *vrf-name* ] neighbors [ *neighbor-address* [ received-routes | routes | advertised-routes | policy [ detail ] ] ]**

**show bgp ipv4 unicast [ vrf *vrf-name* ] cidr-only**

**Parameter  
Description**

| Parameter                                            | Description                                                                                                                                                                                                                                           |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>                                      | VRF name                                                                                                                                                                                                                                              |
| <i>network</i>                                       | Displays the specific routing information in the routing table                                                                                                                                                                                        |
| <i>network-mask</i>                                  | Displays the routing information included in the specified network.                                                                                                                                                                                   |
| <b>longer-prefixes</b>                               | Displays the route map information.                                                                                                                                                                                                                   |
| <b>community</b><br><i>community-number</i>          | Displays the routing information including the specified community value. Community-number can be in the format of AA:NN (autonomous system number / 2-byte number), or the following pre-defined value: internet, no-export, local-as, no-advertise. |
| <b>community-list</b><br><i>community-name</i>       | Displays the BGP routing information matching the specified community-list.                                                                                                                                                                           |
| <b>exact-match</b>                                   | Routing information exactly matching the community value or community-list.                                                                                                                                                                           |
| <b>extcommunity-list</b><br><i>extcommunity-name</i> | Displays the routing information including the specified extcommunity value.                                                                                                                                                                          |
| <b>dampening dampened-paths</b>                      | Displays the restrained routing information.                                                                                                                                                                                                          |
| <b>dampening flap-statistics</b>                     | Displays the routing dampening statistics.                                                                                                                                                                                                            |
| <b>filter-list</b> <i>path-list-number</i>           | Displays the routing information matching the filter-list.                                                                                                                                                                                            |
| <b>inconsistent-as</b>                               | Displays the routing information of the inconsistent source AS.                                                                                                                                                                                       |
| <b>prefix-list</b> <i>ip-prefix-list-name</i>        | Displays the routing information matching the specified prefix-list.                                                                                                                                                                                  |
| <b>quote-regexp</b> <i>regexp</i>                    | Displays the BGP routing information with the AS path attribute matching the specified regexp within the double quote marks.                                                                                                                          |
| <b>regexp</b> <i>regexp</i>                          | Displays the BGP routing information with the AS path attribute matching the specified regexp.                                                                                                                                                        |
| <b>route-map</b> <i>map-tag</i>                      | Displays the routing information matching the specified route-map filtering condition.                                                                                                                                                                |
| <b>neighbors</b>                                     | Displays the BGP IPv4 unicast neighbor information.                                                                                                                                                                                                   |

|                                                                      |                                                                                                               |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| [ <i>neighbor-address</i> ]                                          |                                                                                                               |
| <b>neighbors</b> <i>neighbor-address</i><br><b>received-routes</b>   | Displays all routing information received from the specified peer (including the accepted and refused route). |
| <b>neighbors</b> <i>neighbor-address</i><br><b>routes</b>            | Displays all the routing information received from the peer and accepted.                                     |
| <b>neighbors</b> <i>neighbor-address</i><br><b>advertised-routes</b> | Displays all the routing information sent to the specified peer.                                              |
| <b>neighbors</b> <i>neighbor-address</i><br><b>policy</b>            | Displays the related routing policy information of BGP neighbors. (General)                                   |
| <b>neighbors</b> <i>neighbor-address</i><br><b>policy detail</b>     | Displays the related routing policy information of BGP neighbors. (Detail)                                    |
| <b>cidr-only</b>                                                     | Displays the routing information without the category.                                                        |

Defaults N/A

### Command

**Mode** Privileged EXEC mode

**Usage** Use this command to view the IPv4 unicast route information of BGP. You can filter the information with the specified parameter to display the matching route information.

### Configuration Examples

The following example displays the IPv4 unicast route information of BGP.

```
Ruijie# show bgp ipv4 unicast
BGP table version is 2, local router ID is 192.168.183.1

| <b>show ip bgp</b> | Displays the IPv4 unicast route information of BGP. |

**Platform**

**Description** None

## 5.135 show bgp ipv4 unicast dampening parameters

Use this command to display the IPv4 unicast route dampening parameters configured for the BGP.

**show bgp ipv4 unicast [ vrf *vrf-name* ] dampening parameters**

| Parameter   | Parameter       | Description |
|-------------|-----------------|-------------|
| Description | <i>vrf-name</i> | VRF name    |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage** This command is used to display the IPv4 unicast route dampening parameters configured for BGP.

**Guide**

The following example displays the IPv4 unicast route dampening parameters configured for the BGP.

```
Ruijie(config-router)# bgp dampening 25 10000 10000 200
Ruijie# show bgp ipv4 unicast dampening parameters
dampening 25 10000 10000 200
Dampening Control Block(s):
Reachability Half-Life time : 25 min
Reuse penalty      : 10000
Suppress penalty   : 10000
Max suppress time  : 200 min
Max penalty (ceil) : 29800000
Min penalty (floor) : 5000
```

## 5.136 show bgp ipv4 unicast neighbors

Use this command to display the related information of BGP IPv4 unicast neighbor.

**show bgp ipv4 unicast [ vrf *vrf-name* ] neighbors *neighbor-address***

| Parameter   | Parameter                                              | Description                                                                 |
|-------------|--------------------------------------------------------|-----------------------------------------------------------------------------|
| Description | <i>vrf-name</i>                                        | VRF name                                                                    |
|             | <i>neighbor-address</i>                                | Neighbor IPv4 address                                                       |
|             | <b>neighbors <i>neighbor-address</i> policy</b>        | Displays the related routing policy information of BGP neighbors. (General) |
|             | <b>neighbors <i>neighbor-address</i> policy detail</b> | Displays the related routing policy information of BGP neighbors. (Detail)  |

**Command****Mode** Privileged EXEC mode**Usage****Guide** This command is used to view the information of the connection with BGP IPv4 unicast neighbor.

The following example displays the related information of BGP IPv4 unicast neighbor.

```
Ruijie# show bgp ipv4 unicast neighbors
BGP neighbor is 192.168.195.183, remote AS 23, local AS 23, internal link
  BGP version 4, remote router ID 44.0.0.1
  BGP state = Established, up for 00:06:37
  Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
  Address family IPv4 Unicast: advertised and received
  Graceful restart: advertised and received
  Remote Restart timer is 120 seconds
  Received 14 messages, 0 notifications, 0 in queue
  open message:1 update message:4 keepalive message:9
  refresh message:0 dynamic cap:0 notifications:0
  Sent 12 messages, 0 notifications, 0 in queue
  open message:1 update message:3 keepalive message:8
  refresh message:0 dynamic cap:0 notifications:0
  Route refresh request: received 0, sent 0
  Minimum time between advertisement runs is 0 seconds
  For address family: IPv4 Unicast
  BGP table version 2, neighbor version 1
  Index 2, Offset 0, Mask 0x4
  Inbound soft reconfiguration allowed
  8 accepted prefixes
  0 announced prefixes
  Connections established 2; dropped 1
  Local host: 192.168.195.239, Local port: 1074
  Foreign host: 192.168.195.183, Foreign port: 179
  Nexthop: 192.168.195.239
  Nexthop global: ::
  Nexthop local: ::
  BGP connection: non shared network
  Last Reset: 00:06:43, due to BGP Notification sent
  Notification Error Message: (Cease/Unspecified Error Subcode)
  Using BFD to detect fast fallover
```

## 5.139 show bgp ipv4 unicast update-group

Use this command to display information about an update-group in the BGP IPv4 unicast address family.

**show bgp ipv4 unicast** [ *vrf vrf-name* ] **update-group** [ *neighbor-address* | *update-group-index* ]  
[ **summary** ]

**Parameter Description**

| Parameter                 | Description                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------|
| <i>vrf-name</i>           | Specifies a VRF instance name.                                                                |
| <i>neighbor-address</i>   | Specifies a neighbor that belongs to an update-group whose information needs to be displayed. |
| <i>update-group-index</i> | Specifies an update-group whose information needs to be displayed.                            |
| <b>summary</b>            | Displays neighbor-related information.                                                        |

**Command** Privileged EXEC mode**Mode****Default Level** 14**Usage Guide** This command is used to display information about an update-group in the BGP IPv4 unicast address family.

**Configuration** The following example displays information about an update-group in the BGP IPv4 unicast address family.

**Example**

```
Ruijie#show bgp ipv4 update-group
BGP version 4 update-group 1(ref 2), internal, Address Family: IPv4 Unicast
Update message formated 2, replicated 2
Minimum route advertisement interval is 0 seconds
Minimum AS origination interval is 1 seconds
Format state: Current working
                Refresh blocked
Has 1 members:
    192.168.195.183
```

The following example displays the neighbor summary of update-group 1 in the BGP IPv4 unicast address family.

```
Ruijie # show bgp ipv4 unicast update-group 1 summary
BGP router identifier 192.168.183.1, local AS number 23
BGP table version is 2
2 BGP AS-PATH entries
1 BGP community entries
Neighbor      V   AS  MsgRcvd  MsgSent  TblVer  InQ  OutQ  Up/Down
State/PfxRcd
192.168.195.79 4   24    0        0        0    0    0   never   Active
192.168.195.183 4   23   17       15        1    0    0   00:09:04 8
Total number of neighbors 2
```

| Parameter                                            | Description                                                                                                                                                                                                                                           |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>                                      | VRF name                                                                                                                                                                                                                                              |
| <i>IPv6-prefix</i>                                   | Displays the IPv6 routing information included in the specified network. The input format of the routing information prefix is X:X:X:X::X/<0-128>.                                                                                                    |
| <b>longer-prefixes</b>                               | Displays the route map information.                                                                                                                                                                                                                   |
| <b>community</b><br><i>community-number</i>          | Displays the routing information including the specified community value. Community-number can be in the format of AA:NN (autonomous system number / 2-byte number), or the following pre-defined value: internet, no-export, local-as, no-advertise. |
| <b>community-list</b><br><i>community-name</i>       | Displays the BGP routing information matching the specified community-list.                                                                                                                                                                           |
| <b>exact-match</b>                                   | Routing information exactly matches the community value or community-list.                                                                                                                                                                            |
| <b>extcommunity-list</b><br><i>extcommunity-name</i> | Displays the routing information including the specified extcommunity value.                                                                                                                                                                          |
| <b>dampening</b><br><b>dampened-paths</b>            | Displays the restrained routing information.                                                                                                                                                                                                          |
| <b>dampening flap-statistics</b>                     | Displays the routing dampening statistics.                                                                                                                                                                                                            |

|                                                                      |                                                                                                                              |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>filter-list</b> <i>path-list-number</i>                           | Displays the routing information matching the filter-list.                                                                   |
| <b>inconsistent-as</b>                                               | Displays the routing information of the inconsistent source AS.                                                              |
| <b>prefix-list</b><br><i>ipv6-prefix-list-name</i>                   | Displays the routing information matching the specified prefix-list.                                                         |
| <b>quote-regexp</b> <i>regexp</i>                                    | Displays the BGP routing information with the AS path attribute matching the specified regexp within the double quote marks. |
| <b>regexp</b> <i>regexp</i>                                          | Displays the BGP routing information with the AS path attribute matching the specified regexp.                               |
| <b>route-map</b> <i>map-tag</i>                                      | Displays the routing information matching the specified route-map filtering condition.                                       |
| <b>neighbors</b><br>[ <i>neighbor-address</i> ]                      | Displays the BGP IPv6 unicast neighbor information.                                                                          |
| <b>neighbors</b> <i>neighbor-address</i><br><b>received-routes</b>   | Displays all routing information received from the specified peer (including accepted and refused routes).                   |
| <b>neighbors</b> <i>neighbor-address</i><br><b>routes</b>            | Displays all the routing information received from the peer and accepted.                                                    |
| <b>neighbors</b> <i>neighbor-address</i><br><b>advertised-routes</b> | Displays all the routing information sent to the specified peer.                                                             |
| <b>neighbors</b> <i>neighbor-address</i><br><b>policy</b>            | Displays the related routing policy information of BGP neighbors. (General)                                                  |
| <b>neighbors</b> <i>neighbor-address</i><br><b>policy detail</b>     | Displays the related routing policy information of BGP neighbors. (Detail)                                                   |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage Guide**

Use this command to view the IPv6 unicast route information of BGP. You can filter the information with the specified parameter to display the matching route information. The function and use of this command is similar to the **show bgp ipv4 unicast** command, please refer to the command.

**Configuration**

**Examples** N/A

**Description** None

## 5.141 show bgp ipv6 unicast dampening parameters

Use this command to display the IPv6 unicast route dampening parameters configured for BGP.

**show bgp ipv6 unicast [ vrf *vrf-name* ] dampening parameters**

| Parameter   | Parameter       | Description |
|-------------|-----------------|-------------|
| Description | <i>vrf-name</i> | VRF name.   |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage****Guide**

This command is used to display the IPv6 unicast route dampening parameters configured for the BGP. The function and use of this command are similar to the **show bgp ipv4 unicast dampening parameters** command. Please refer to the command.

**Configuration**

**Examples** N/A

## 5.143 show bgp ipv6 unicast paths

Use this command to display the path information of the IPv6 unicast in the route database.

**show bgp ipv6 unicast [ vrf *vrf-name* ] paths**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
| vrf-name  | VRF name    |

**Defaults** N/A

### Command

**Mode** Privileged EXEC mode

### Usage

**Guide** This command is used to view the path information in the route database.

The following example displays the path information of the IPv6 unicast in the route database.

### Configuration Examples

```
Ruijie# show bgp ipv6 unicast paths
Address Refcnt Path
[0x1d7806a0:0] (67)
[0x1d7389a0:13] (20) 10
```

## 5.144 show bgp ipv6 unicast summary

Use this command to display the related information of BGP IPv6 unicast.

**show bgp ipv6 unicast [ vrf *vrf-name* ] summary**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | vrf-name  | VRF name.   |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage  
Guide**

This command is used to display the related information of BGP IPv6 unicast. The function and use of this command are similar to the **show bgp ipv4 unicast summary** command. Please refer to the command.

|                     | <b>show bgp ipv4 unicast summary</b> | Displays the related information of BGP IPv4 unicast. |

**Platform**

**Description** None

## 5.145 show bgp ipv6 unicast update-group

Use this command to display information about an update-group in the BGP IPv6 unicast address family.

**show bgp ipv6 unicast [ vrf *vrf-name* ] update-group [ *neighbor-address* | *update-group-index* ] [ summary ]**

| Parameter<br>Description | Parameter                 | Description                                                                                   |
|--------------------------|---------------------------|-----------------------------------------------------------------------------------------------|
|                          | <i>vrf-name</i>           | Specifies a VRF instance name.                                                                |
|                          | <i>neighbor-address</i>   | Specifies a neighbor that belongs to an update-group whose information needs to be displayed. |
|                          | <i>update-group-index</i> | Specifies an update-group whose information needs to be displayed.                            |
|                          | <b>summary</b>            | Displays neighbor-related information.                                                        |

**Command** Privileged EXEC mode

**Mode****Default Level** 14**Usage Guide** This command is used to display information about an update-group in the BGP IPv6 address family.**Configuration Example** The following example displays information about an update-group in the BGP IPv6 unicast address family.

```
Ruijie#show bgp ipv6 update-group
BGP version 4 update-group 1(ref 2), internal, Address Family: IPv6 Unicast
Update message formatted 2, replicated 2
Minimum route advertisement interval is 0 seconds
Minimum AS origination interval is 1 seconds
Format state: Current working
                Refresh blocked
Has 1 members:
    192:168:195::183
```

The following example displays the neighbor summary of update-group 1 in the BGP IPv6 unicast address family.

```
Ruijie # show bgp ipv6 unicast update-group 1 summary
BGP router identifier 192.168.183.1, local AS number 23
BGP table version is 2
2 BGP AS-PATH entries
1 BGP community entries
Neighbor      V   AS  MsgRcvd  MsgSent  TblVer  InQ   OutQ  Up/Down
State/PfxRcd
192:168:195::79  4   24    0        0        0    0    0   never    Active
192:168:195::183 4   23   17        15        1    0    0   00:09:04  8
Total number of neighbors 2
```

**Platform Description** N/A

## 5.146 show bgp l2vpn

Use the following command to display the BGP L2VPN routing information.

**show bgp l2vpn { evpn } all**

Use the following command to display the neighbor information of the BGP L2VPN EVPN address family.

**show bgp l2vpn evpn all { ethernet-ad | ethernet-segment | inclusive-multicast | ip-prefix | mac-ip } [ detail ]**

Use the following command to display the second type routing information of the BGP L2VPN EVPN address family.

**show bgp l2vpn evpn all mac-ip mac\_addr [ ip\_addr [ detail ] | ipv6\_addr [ detail ] | detail ]**

Use the following command to display the fifth type routing information of the BGP L2VPN EVPN address family.

**show bgp l2vpn evpn all ip-prefix { ip\_addr [ detail ] | ipv6\_addr [ detail ] | detail }**

Use the following command to display the neighbor information of the BGP L2VPN address family.

**show bgp l2vpn { evpn } all neighbor [ peer-address [ policy [ detail ] ] ]**

Use the following command to display the neighbor summary information of the BGP L2VPN address family.

**show bgp l2vpn { evpn } all summary**

Use the following command to display the L2VPN EVPN information on the specified RD.

**show bgp l2vpn evpn rd vpn\_rd [[ethernet-ad | ethernet-segment | inclusive-multicast | ip-prefix | mac-ip ] [ detail ]]**

Use the following command to display the L2VPN EVPN information on the specified EVI.

**show bgp l2vpn evpn evi vni-id [ [ ethernet-ad | ethernet-segment | inclusive-multicast | ip-prefix | mac-ip ] [ detail ] ]**

| Parameter                                                                 | Description                                                                                                                                                                                                      |
|---------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 5.148 show bgp statistics

Use this command to display the BGP statistics information.

**show bgp statistics [ vrf vrf-name ]**

| Parameter          | Parameter    | Description                                     |
|--------------------|--------------|-------------------------------------------------|
| <b>Description</b> | vrf vrf-name | Displays the BGP statistics information of VRF. |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage**

**Guide** Without the **vrf** parameter, the global BGP statistics information will be displayed.

The following example displays the BGP statistics information.

```
Ruijie#show bgp statistics
Local as 100, Router id 1.1.1.1
  Total neighbor 10, Established neighbor 9, Admin-Down neighbor 1
  IBGP neighbor 8, Established IBGP neighbor 8, Admin-Down IBGP neighbor
0
  EBGp neighbor 2, Established EBGp neighbor 1, Admin-Down EBGp neighbor
1
  AS-PATH entries 1, Community entries 1, Extended-Community entries 0

For address family: IPv4 Unicast
  Activated neighbor 9, Unactivated neighbor 0
  Activated IBGP neighbor 8, Unactivated IBGP neighbor 0
  Activated EBGp neighbor 1, Unactivated EBGp neighbor 0

For address family: IPv6 Unicast
  Activated neighbor 0, Unactivated neighbor 9
  Activated IBGP neighbor 0, Unactivated IBGP neighbor 0
  Activated EBGp neighbor 0, Unactivated EBGp neighbor 0
```

**Configuration Examples**

| Parameter                 | Description                                                  |
|---------------------------|--------------------------------------------------------------|
| Router id                 | ID of BGP router.                                            |
| Total neighbor            | Total number of neighbors.                                   |
| Established neighbor      | Number of UP neighbors.                                      |
| Admin-Down neighbor       | Number of admin down neighbors.                              |
| IBGP neighbor             | Number of IBGP neighbors.                                    |
| Established IBGP neighbor | Number of UP IBGP neighbors.                                 |
| Admin-Down IBGP neighbor  | Number of admin down IBGP neighbors.                         |
| EBGP neighbor             | Number of EBGp neighbors.                                    |
| AS-PATH entries           | Number of AS-PATH entries.                                   |
| Community entries         | Number of community entries.                                 |
| Extended-Community        | Number of extended community entries.                        |
| Established EBGp neighbor | Number of UP EBGp neighbors.                                 |
| Admin-Down EBGp neighbor  | Number of admin down EBGp neighbors.                         |
| Activated neighbor        | Number of activated neighbors.                               |
| Unactivated neighbor      | Number of unactivated neighbors, not including UP neighbors. |
| Activated IBGP neighbor   | Number of activated IBGP neighbors.                          |

|                           |                                                                   |
|---------------------------|-------------------------------------------------------------------|
| Unactivated IBGP neighbor | Number of unactivated IBGP neighbors, not including UP neighbors. |
| Activated EBGP neighbor   | Number of activated EBGP neighbors.                               |
| Unactivated EBGP neighbor | Number of unactivated EBGP neighbors, not including UP neighbors. |

**Platform**

**Description** N/A

### 5.149 show evpn

Use this command to display the EVI instance.

**show evpn [ vni-id [detail] / detail ]**

| Parameter          | Parameter | Description                                 |
|--------------------|-----------|---------------------------------------------|
| <b>Description</b> | vni-id    | Indicates the ID of specified EVI instance. |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage Guide** If an ID of EVI instance is exported, display the information of the EVI. IF no EVI ID is imported, display all EVIs' information.

The following example displays all information of EVI 100.

```
Ruijie#show evpn 100 detail
EVI 100, RD 1.1.1.1:100(auto)
  Import VPN route-target communities
    RT: 100:100(auto)
  Export VPN route-target communities
    RT: 100:100(auto)
EVI Layer 3 Interface: OverlayRouter 100
All Route count: 6
  Ethernet Auto-discovery Route count: 0
  MAC/IP Advertisement Route count: 4
  Inclusive Multicast Ethernet Tag Route count: 2
  Ethernet Segment Route count: 0
  Install Route count: 3
```

**Configuration Examples**

| Parameter | Description      |
|-----------|------------------|
| RD        | RD value of EVI. |

|                                     |                                   |
|-------------------------------------|-----------------------------------|
| EVI Layer 3 Interface               | L3 interface associated with EVI. |
| Export VPN route-target communities | Value of the exported RT of EVI.  |
| Import VPN route-target communities | Value of the imported RT of EVI.  |
| Route count                         | Number of routes in EVI instance. |

The following example displays key information of EVI.

```
Ruijie#show evpn
vni      rd                interface
100      1.1.1.1:100        OverlayRouter 100
300      1.1.1.1:300        N/A
789      1.1.1.1:789        N/A
1000     1.1.1.1:1000       OverlayRouter 1000
1122     1:100              N/A
2000     1.1.1.1:2000       OverlayRouter 2000
3344     1.1.1.1:3344       N/A
1678889  1.1.1.1:40489      N/A
Total number: 8
```

| Parameter | Description                       |
|-----------|-----------------------------------|
| vni       | vni-id of EVI.                    |
| rd        | RD value of EVI                   |
| interface | L3 interface associated with EVI. |

### 5.150 show evpn mac

Use this command to display the mobilized or conflict MAC information

**show evpn mac {conflict | mobility} [ vni-id ]**

**Parameter Description**

| Parameter       | Description                             |
|-----------------|-----------------------------------------|
| <b>conflict</b> | Display the conflicted MAC              |
| <b>mobility</b> | Display the mobilized MAC               |
| <i>vni-id</i>   | Display the ID of specific EVI instance |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage** If the parameter has EVI ID, then display the MAC information of specific EVI; if no EVI ID is entered, display the MAC information of all EVI.

**Guide**

The following example checks the mobilized MAC information.

```
Ruijie#show evpn mac mobility
vni    mac                count  remain-time
10     0055.1000.0004       2      72
10     0055.1000.000a       1      66
10     0055.1000.000e       1      72
10     0055.1000.0013       1      27
10     0055.1000.0015       4      75
```

**Configuration**

**Examples**

| Parameter   | Description                                             |
|-------------|---------------------------------------------------------|
| vni         | VNI-ID of EVI.                                          |
| mac         | Mobilized MAC address                                   |
| count       | Mobility times                                          |
| remain-time | Remaining time of the timer for conflict. Unit: second. |

The following example checks the conflict MAC information.

```
Ruijie#show evpn mac conflict
Ruijie#show evpn mac conflict
vni    mac                seq    retry-time
10     0011.0011.e69c      6      -
```

| Parameter  | Description                             |
|------------|-----------------------------------------|
| vni        | vni-id of EVI.                          |
| mac        | Mobilized MAC address                   |
| seq        | Sequence number of conflict MAC address |
| Retry-time | Remaining time for retry. Unit: second  |

## 5.151 show ip bgp

Use this command to display the BGP IPv4 unicast address families' route information. The method of use is the same as other BGP show commands.

**show ip bgp** [ *vrf vrf-name* ] [ *network* [ *network-mask* [ **longer-prefixes** ] ] ] | **cidr-only** | **community** [ *community-number* [ **exact-match** ] ] | **filter-list** *path-list-number* | **community-list** *community-name* [ **exact-match** ] | **regex** *regex* | **quote-regex** *regex* | **extcommunity-list** *extcommunity-name* | **inconsistent-as** | **prefix-list** *ip-prefix-list-name* | **route-map** *map-tag* ]

Display route flap's parameters.

**show ip bgp** [ *vrf vrf-name* ] **dampening** { **flap-statistics** | **dampened-paths** | **parameters** }

Display neighbors' related information.

**show ip bgp** [ *vrf vrf-name* ] **neighbors** [ *peer-address* [ **received-routes** | **routes** | **advertised-routes** [ **policy** [ **detail** ] ] ] ]

**show ip bgp** [ *vrf vrf-name* ] **summary**

Display directory information.

**show ip bgp** [ *vrf vrf-name* ] **paths**

Display route scan status.

**show ip bgp scan**

Display related information under VRF.

**show ip bgp** { *vrf vrf-name* | **labels** }

Display related information of BGP IPv4 unicast update-group.

**show ip bgp** [ *vrf vrf-name* ] **update-group** [ *neighbor-address* | *update-group-index* ] [ **summary** ]

**Parameter Description**

| Parameter                                            | Description                                                                                                                                                                                                                                                       |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i>                                      | VRF name.                                                                                                                                                                                                                                                         |
| <i>network</i>                                       | Displays specific route information in the route table.                                                                                                                                                                                                           |
| <i>network-mask</i>                                  | Displays route information in the specific network.                                                                                                                                                                                                               |
| <b>longer-prefixes</b>                               | Displays the route map information.                                                                                                                                                                                                                               |
| <b>cidr-only</b>                                     | Displays route information without specific category.                                                                                                                                                                                                             |
| <b>community</b><br><i>community-number</i>          | Displays route information containing specific community value. The <i>community-number</i> is the group number. The format is AA:NN (autonomous system number/2-byte figure), or the following pre-defined value: internet, no-export, local-as or no-advertise. |
| <b>community-list</b><br><i>community-name</i>       | Displays the BGP route information of the specified community list. The <i>community-name</i> is the name of the community list.                                                                                                                                  |
| <b>dampening</b><br><b>dampened-paths</b>            | Displays dampened route information.                                                                                                                                                                                                                              |
| <b>dampening flap-statistics</b>                     | Displays the route flap statistics.                                                                                                                                                                                                                               |
| <b>dampening parameters</b>                          | Displays believed route flap parameters.                                                                                                                                                                                                                          |
| <b>extcommunity-list</b><br><i>extcommunity-name</i> | Displays route information containing specific extcommunity value.                                                                                                                                                                                                |
| <b>filter-list</b> <i>path-list-number</i>           | Displays the route information that complies with the filter list. The                                                                                                                                                                                            |

|                                                                                   |                                                                                                                                                                                                                                                 |

**Defaults** -

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** The **show ip bgp** command is the same as **show bgp ipv4 unicast** in terms of the function. All the parameters in **show bgp ipv4 unicast** apply to **show ip bgp**.

**Configuration** -

**Examples**

**Configuration**

**Examples**

| Command                      | Description                                                       |
|------------------------------|-------------------------------------------------------------------|
| <b>show bgp ipv4 unicast</b> | Displays IPv4 unicast route information in BGP route information. |

Platform -  
Description

## 5.152 vni

Use this command to create an EVI instance. Use the **no** form of this command to delete the EVI instance. Use the **default** form of this command to restore the default settings.

**vni** *vni-id*

**no vni** *vni-id*

**default vni** *vni-id*

| Parameter   | Parameter     | Description                                      |
|-------------|---------------|--------------------------------------------------|
| Description | <i>vni-id</i> | Indicates the VNI ID. Ranges from 1 to 16777215. |

Defaults N/A

### Command

Mode EVPN configuration mode

### Usage

Configure the EVPN mode first, and then enter the evpn-vni configuration mode. Run exit command to exit.

### Guide

### Configuration

The following example configures an EVI instance in EVPN mode.

### Examples

```
Ruijie(config)# evpn
Ruijie(config-evpn)# vni 100
```

**Description**

### 6.3 ip local policy route-map

Use this command to apply the policy-based routing ( PBR ) on the packets sent locally. Use the **no** form of this command to restore the default setting.

**ip local policy route-map** *route-map*

**no ip local policy route-map**

| Parameter Description | Parameter | Description           |
|-----------------------|-----------|-----------------------|
|                       |           | <i>route-map-name</i> |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is valid for the IP packets sent locally, but not the IP packets received locally. The IP packets received by the local are free from this command.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

The **set interface** command for the policy-based routing does not support the load-balancing and only supports the redundancy backup.

**Configuration Examples** The following examples send the packets with the source address 192.168.217.10 from the serial 2/0. The following example defines an ACL that match the IP packet.

```
Ruijie(config)#access-list 1 permit 192.168.217.10
```

The following example defines the route map.

```
Ruijie(config)#route-map lab1 permit 10
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set interface serial 2/0
Ruijie(config-route-map)#exit
```

The following example applies PBR on the local interface.

```
Ruijie(config)#ip local policy route-map lab1
```

## Description

## 6.4 ip policy

Use this command to set the policy: redundant backup or load balancing used between multiple next hops of the PBR applied for the **set ip [ default ] nexthop** command in global configuration mode.

Use the **no** form of this command to restore the default setting.

**ip policy { load-balance | redundancy }**

**no ip policy**

Parameter  
Description

| Parameter                        | Description                                               |
|----------------------------------|-----------------------------------------------------------|
| <b>load-balance   redundancy</b> | Specifies the policy: load balancing or redundant backup. |

## Defaults

Redundant backup is adopted by default.

Command  
Mode

Global configuration mode

## Usage Guide

When you configure the **set ip next-hop** command in sub-route map, it is possible to configure

multiple next hops. However, when you set redundant backup, only the first resolved next hop of the policy-based routing takes effect. When the load balancing is set, multiple resolved next hops of the policy-based routing take effect. The WCMP can be set up to 8 next hops, and the ECMP can be set up to 32 next hops. The resolved next hop refers to the ARP message learned by the next hop and the MAC address corresponding to this ARP exists in the MAC address table.

 NPE80 does not support this command.

**Configuration Examples** In the example below, there are multiple next hops configured in the route map. After the redundant backup is set in global configuration mode, only the first next hop among the sub-route map of the policy-based routing applied on the interface FastEthernet 0/0 takes effect.

The following example sets the ACL that match the IP packet.

```
Ruijie(config)#access-list 1 permit 10.0.0.1
Ruijie(config)#access-list 2 permit 20.0.0.1
```

The following example defines the route map.

```
Ruijie(config)#route-map lab1 permit 10
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip next-hop 196.168.4.6
Ruijie(config-route-map)#set ip next-hop 196.168.4.7
Ruijie(config-route-map)#set ip next-hop 196.168.4.8
Ruijie(config-route-map)#exit
Ruijie(config)#route-map lab1 permit 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set ip next-hop 196.168.5.6
Ruijie(config-route-map)#set ip next-hop 196.168.5.7
Ruijie(config-route-map)#set ip next-hop 196.168.5.8
Ruijie(config-route-map)#exit
```

The following example applies the policy-based routing on the interface.

```
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ip policy route-map lab1
Ruijie(config-if)#exit
Ruijie(config)#ip policy redundance
```

## 6.5 ip policy route-map

Use this command to apply the policy-based routing on an interface. Use the **no** form of this command to restore the default setting.

**ip policy route-map** *route-map*

**no ip policy route-map**

| Parameter Description | Parameter        | Description           |
|-----------------------|------------------|-----------------------|
|                       | <i>route-map</i> | Name of the route map |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The policy-based routing must be applied on the specified interface. That interface performs the policy-based routing only on the received packets.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

 Up to one route map can be configured on an interface. When you configure a route map on the interface for many times, the latter will overwrite the former.

**Configuration Examples** In the example below, when the interface FastEthernet0/0 receives a datagram, if the source address of the datagram is 10.0.0.1, it sets the next-hop as 196.168.4.6; if the source address is 20.0.0.1, it sets the next-hop as 196.168.5.6; otherwise, the general forwarding will be performed.

The following example sets the ACL matched with the IP packets.

```
Ruijie(config)#access-list 1 permit 10.0.0.1
Ruijie(config)#access-list 2 permit 20.0.0.1
```

The following example defines the route map.

```
Ruijie(config)#route-map lab1 permit 10
Ruijie (config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip next-hop 196.168.4.6
Ruijie(config-route-map)#exit
Ruijie(config)#route-map lab1 permit 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set ip next-hop 196.168.5.6
Ruijie(config-route-map)#exit
```

The following example applies the route map on the interface.

```
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ip policy route-map lab1
Ruijie(config-if)#exit
```

**Related Commands**

**Description**

## 6.6 ip policy-source in-interface

Use this command to configure the source address policy-based routing for the IPv4 packets received on an interface. Use the **no** form of this command to disable the source address policy-based routing on the interface.

**ip policy-source in-interface** *interface-type* *sequence* { *source-address mask* | *source-address/mask* } **[default]** **next-hop** *ip-address* [*weight*] | **[default]** **interface** *out-interface-type* | **vrf** *vrf-name*}

**no ip policy-source in-interface** *interface-type* *sequence* [ { *source-address mask* | *source-address/mask* } [ **[default]** **next-hop** *ip-address* [*weight*] | **[default]** **interface** *out-interface-type* | **vrf** *vrf-name* ] ]

**Parameter Description**

| Parameter             | Description                                                     |
|-----------------------|-----------------------------------------------------------------|
| <i>interface-type</i> | Interface type                                                  |
| <i>sequence</i>       | Policy sequence number. The lower the number is, the higher the |

|                           |                                |
|---------------------------|--------------------------------|
|                           | priority is.                   |
| <i>source-address</i>     | Source IPv4 address.           |
| <i>mask</i>               | Address mask.                  |
| <i>ip-address</i>         | Next hop IPv4 address          |
| <i>weight</i>             | Next hop weight                |
| <i>out-interface-type</i> | Type of the next hop interface |
| <i>vrf-name</i>           | VRF instance name              |

**Defaults** Source address policy-based routing is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** You can configure multiple **ip source-policy in-interface** commands on an interface. The policy with different source addresses must be configured with different sequence numbers. The lower the sequence number is, the higher the priority is.

In case of the same sequence number, the priority order of the next hop type is as follows:

**vrf vrf-name > next-hop ip-address > interface out-interface-type > default next-hop ip-address > default interface out-interface-type**

The priority of the source address PBR is lower than that of the interface PBR.

**Configuration Examples** In the example below, when the interface GigabitEthernet0/0 receives a datagram, if the source address of the datagram is 10.0.0.2, the next-hop is set as 196.168.1.2; otherwise, the general forwarding will be performed.

The following example configures source address PBR in global configuration mode.

```
Ruijie(config)# ip source-policy in-interface gigabitEthernet 0/0 1 10.0.0.2
255.255.255.255 next-hop 196.168.1.2
Ruijie(config)# ip source-policy in-interface gigabitEthernet 0/0 2 20.0.0.2
255.255.255.255 next-hop 196.168.2.2
```

**Description**

## 6.7 ipv6 local policy route-map

Use this command to enable the policy-based routing on the packets sent locally. Use the **no** form of this command to restore the default setting.

**ipv6 local policy route-map route-map-name**

**no ipv6 local policy route-map**

| Parameter Description | Parameter             | Description                                                                                   |
|-----------------------|-----------------------|-----------------------------------------------------------------------------------------------|
|                       | <i>route-map-name</i> | Name of the router map applied locally, which is configured by the <b>router-map</b> command. |

**Defaults** This function is disabled by default.

**Command Mode** Global Configuration mode

**Usage Guide**

- This command is valid only for the IPv6 packets in accordance with the policy (for example, ping packets used for management) sent locally, but not the packets received locally.
- To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

**Configuration Examples** The following examples display the PBR application process: The device sends the packets from the source address 2003:1000::10/80 to the 2001:100::/64, the packets will match ACL6 of aaa and be sent to the device 2003:1001::2.

- The following example defines the ACL matched with the IPv6 packet:

```
Ruijie(config)#ipv6 access-list aaa
Ruijie(config)#permit ipv6 2003:1000::10/80 2001:100::/64
```

- The following example defines the router map.

```
Ruijie(config)#route-map pbr-aaa permit 10
Ruijie(config-route-map)#match ipv6 address aaa
Ruijie(config-route-map)#set ipv6 next-hop 2003::1001::2
```

- The following example applies the PBR on the device.

```
Ruijie(config)#ipv6 local policy route-map pbr-aaa
```

**Platform** N/A

**Description**

## 6.8 ipv6 policy

Use this command to set the policy: redundant backup or load balancing, applied for the **set ip nexthop** command in global configuration mode. Use the **no** form of this command to restore the default setting.

**ipv6 policy { load-balance | redundancy }**

**no ipv6 policy**

**Parameter Description**

| Parameter           | Description                          |
|---------------------|--------------------------------------|
| <b>load-balance</b> | Sets the policy as load balancing.   |
| <b>redundance</b>   | Sets the policy as redundant backup. |

**Defaults** Redundant backup is adopted by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is valid for the IP packets sent locally, but not the IP packets received locally. The IP packets received by the local are free from this command.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

The **set interface** command for the policy-based routing does not support the load-balancing and only supports the redundancy backup.

**Configuration** This function is valid for the multiple next-hops.

**Examples** When you configure the set ip next-hop command in sub-route map, it is possible to configure multiple next hops. However, when you set redundant backup, only the first resolved next hop takes effect. The second configured next hop will take effect only when the first one fails and the first next hop will take effect again if it recovers.

When the load balancing is set, multiple next hops of the policy-based routing take effect.

The WCMP can be set up to 8 next hops, and the ECMP can be set up to 32 next hops.

 The resolved next hop refers to the learned MAC address for the next-hop.

The following example sets load-balancing mode for multiple nexthops.

The following example configures an ACL matching with IP packets.

```
Ruijie(config)# ipv6 access-list 1
Ruijie(config-ipv6-acl )# permit ipv6 1000::1 any
Ruijie(config)# ipv6 access-list 2
Ruijie(config-ipv6-acl )# permit ipv6 2000::1 any
```

The following example defines a route map.

```
Ruijie(config)# route-map lab1 permit 10
Ruijie(config-route-map)# match ipv6 address 1
Ruijie(config-route-map)# set ipv6 next-hop 2002::1
Ruijie(config-route-map)# set ipv6 next-hop 2002::2
Ruijie(config-route-map)# set ipv6 next-hop 2002::3
Ruijie(config-route-map)# exit
Ruijie(config)# route-map lab1 permit 20
Ruijie(config-route-map)# match ipv6 address 2
Ruijie(config-route-map)# set ipv6 next-hop 2002::5
Ruijie(config-route-map)# set ipv6 next-hop 2002::6
Ruijie(config-route-map)# set ipv6 next-hop 2002::7
Ruijie(config-route-map)# exit
```

The following example applies policy-based routing on the interface.

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# ipv6 policy route-map lab1
Ruijie(config-if)# exit
Ruijie(config)# ipv6 policy load-balance
```

**Description**

## 6.9 ipv6 policy route-map

Use this command to apply the policy-based routing on an interface in interface configuration mode.

Use the **no** form of this command to restore the default setting.

**ipv6 policy route-map** *route-map-name*

**no ip policy route-map****Parameter  
Description**

| Parameter             | Description                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------------------|
| <i>route-map-name</i> | Name of the PBR router map applied locally, which is configured by the <b>router-map</b> command. |

**Defaults**

This function is disabled by default..

**Command**

Interface configuration mode

**Mode****Usage Guide**

The policy-based routing must be applied on the specified interface. That interface performs the policy-based routing only on the received packets.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

 Up to one route map can be configured on an interface. When you configure a route map on the interface for many times, the latter will overwrite the former.

**Configuration**

An IPv6 packet is received on the fastEthernet 0/0. If the packet is sent from 10::/64 network

**Examples**

segment, it is forwarded to the next hop of 2000:1; if the packet is sent from 20::/64 network segment, it is forwarded to the next hop of 2000:2 or forwarded as usual.:

The following example configures an ACL matched with the IP packet.

```
Ruijie(config)# ipv6 access-list acl_for_pbr1
Ruijie (config-ipv6-acl)# permit ipv6 10::/64 any
Ruijie(config)# ipv6 access-list acl_for_pbr2
Ruijie (config-ipv6-acl)# permit ipv6 20::/64 any
```

The following example defines a route map.

```
Ruijie(config)# route-map rm_pbr permit 10
Ruijie (config-route-map)# match ipv6 address acl_for_pbr1
Ruijie(config-route-map)# set ipv6 next-hop 2000::1
Ruijie(config-route-map)# exit
Ruijie(config)# route-map rm_pbr permit 20
Ruijie(config-route-map)# match ipv6 address acl_for_pbr2
Ruijie(config-route-map)# set ipv6 next-hop 2000::2
Ruijie(config-route-map)# exit
```

The following example applies the route map to the interface.

```
Ruijie(config)# interface FastEthernet 0/0
Ruijie(config-if)# no switchport
Ruijie(config-if)# ipv6 policy route-map rm_pbr
```

```
Ruijie(config-if) # exit
```

**Description**

## 6.10 ipv6 policy-source in-interface

Use this command to configure the source address policy-based routing for the IPv6 packets received on an interface. Use the **no** form of this command to disable the source address policy-based routing on the interface.

**ipv6 policy-source in-interface** *interface-type* *sequence* *source-address/prefix-length* {[**default**] **next-hop** *ipv6-address* [*weight*] ]} [**default**] **interface** *out-interface-type* | **vrf** *vrf-name* }  
**no ipv6 policy-source in-interface** *interface-type* *sequence* [ *source-address/prefix-length* [ [**default**] **next-hop** *ipv6-address* [*weight*] ] ] [**default**] **interface** *out-interface-type* | **vrf** *vrf-name* }

**Parameter  
Description**

| Parameter                 | Description                                                                  |
|---------------------------|------------------------------------------------------------------------------|
| <i>interface-type</i>     | Interface type                                                               |
| <i>sequence</i>           | Policy sequence number. The lower the number is, the higher the priority is. |
| <i>source-address</i>     | Source IPv6 address.                                                         |
| <i>ipv6-address</i>       | Next hop IPv6 address                                                        |
| <i>weight</i>             | Next hop weight                                                              |
| <i>out-interface-type</i> | Type of the next hop interface                                               |
| <i>vrf-name</i>           | VRF instance name                                                            |

**Defaults** Source address PBR is disabled by default.

**Command  
Mode** Global configuration mode

**Usage Guide** You can configure multiple **ipv6 source-policy in-interface** commands on an interface. The policy with different source addresses must be configured with different sequence numbers. The lower the sequence number is, the higher the priority is.

In case of the same sequence number, the priority order of the next hop type is as follows:

```
vrf vrf-name > next-hop ipv6-address > interface out-interface-type> default next-hop
ipv6-address > default interface out-interface-type
```

The priority of the source address PBR is lower than that of the interface PBR.

**Configuration Examples** In the example below, when the interface GigabitEthernet0/0 receives an IPv6 datagram, if the source address of the datagram is in the network segment of 10::/64, the next-hop is set as 2000:1; if the source address of the datagram is in the network segment of 20::/64, the next-hop is set as 2000:2; otherwise, the general forwarding will be performed.

The following example configures source address PBR in global configuration mode.

```
Ruijie(config)# ipv6 source-policy in-interface gigabitEthernet 0/0 2 10::/64
next-hop 2000::1
Ruijie(config)# ipv6 source-policy in-interface gigabitEthernet 0/0 2 20::/64
next-hop 2000::2
```

| PBR IPv4 Route Summay | IPv4 PBR route count.                                                                                                                                                                                                                                                                                                                                                                     |
| Interface             | Interface where IPv4 PBR is enabled.                                                                                                                                                                                                                                                                                                                                                      |
| Sequence              | The PBR serial number.                                                                                                                                                                                                                                                                                                                                                                    |
| ACL                   | The ACL ID used in the match rule.                                                                                                                                                                                                                                                                                                                                                        |
| ACL_CLS               | The ACL type used in the match rule, such as the IP standard ACL.                                                                                                                                                                                                                                                                                                                         |
| Min Length            | The minimum match length.                                                                                                                                                                                                                                                                                                                                                                 |
| Max Length            | The maximum match length.                                                                                                                                                                                                                                                                                                                                                                 |
| VRF ID                | Port-correlated VRF ID.                                                                                                                                                                                                                                                                                                                                                                   |
| Route Flags           | PBR flag bit:<br>Route Type: "PBR" indicates PBR routes.<br>"Normal" indicates common routes.<br>Direct: PBR matching action, <b>permit</b> or <b>deny</b><br>Priority: PBR priority, <b>High</b> or <b>Low</b><br>Tos_Dscp: Displays whether the <b>tos</b> rule or the <b>dscp</b> rule is configured.<br>Precedence: Displays whether the <b>set ip precedence</b> rule is configured. |
| Mode                  | Specifies the redundancy mode or the next hop load balancing mode.                                                                                                                                                                                                                                                                                                                        |
| NextHop Count         | Specifies the next hop number. ECMP supports up to 32 next hops.                                                                                                                                                                                                                                                                                                                          |

|         |                                                                       |
|---------|-----------------------------------------------------------------------|
| Nexthop | Specifies the next hop IP address.                                    |
| Weight  | Specifies the next hop weight.                                        |
| lfindex | Specifies the outbound interface index corresponding to the next hop. |

### 6.13 show ip pbr route-map

Use this command to display the IPv4 PBR route-map information.

**show ip pbr route-map** *route-map-name*

| Parameter Description | Parameter | Description           |
|-----------------------|-----------|-----------------------|
|                       |           | <i>route-map-name</i> |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv4 PBR route-map information.

```

Examples
Ruijie#show ip pbr route-map rm
Pbr VRF: GLOBAL, ID: 0
Forward Mode: redundance
Forwarding: On

route-map rm
route-map index: sequence 10, permit
Match rule:
ACL ID : 0, ACL CLS: 0, Name: acl1
Set rule:
IPv4 Nexthop: 192.168.8.100, (VRF Name: , ID: 0), Weight: 0, Flags: 0
PBR state info ifx: GigabitEthernet 0/1, Connected: true, Track State:
Up
    
```

| Field           | Description                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------|
| Pbr VRF         | VRF name and VRF ID.                                                                         |
| Forward Mode    | Sets the load balance mode or the redundancy mode for the next hop.                          |
| Forwarding      | Displays whether the IP route forwarding is enabled.                                         |
| Route-map index | The serial number and the type of the sub-map.                                               |
| Match rule      | Match rule.                                                                                  |
| Set rule        | Set rule.                                                                                    |
| PBR state info  | PBR private data information, such as outbound interface and the link state of the next hop. |

## 6.14 show ip pbr source-route

Use this command to display information about IPv4 source address-based PBR.

**show ip pbr source-route [ interface *if-name* ]**

#### Parameter Description

| Parameter                       | Description                                                                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface <i>if-name</i></b> | Displays the IPv4 PBR applied to a specified interface if <i>if-name</i> is specified.<br>Displays all applied IPv4 PBR information if <i>if-name</i> is not specified. |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** You can use this command to display the configured source address-based PBR.

**Configuration Examples** The following example displays information about the configured source address-based PBR.

```
Ruijie# show ip pbr source-route
PBR IPv4 Source Route
Interface      : GigabitEthernet 0/1
Sequence      : 10
```

```

Source address : 10.1.1.1/24
VRF ID        : 0
Route Flags   :
Route Type    : PBR
Direct        : Permit
Priority       : High
Match_ipaddr  : Exist
Mode          : redundance
Nexthop Count : 1
Nexthop[0]    : 192.168.8.100
Weight[0]     : 1
Ifindex[0]    : 2
    
```

|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface     | Interface to which the PBR is applied                                                                                                                                                                                                                                                                                     |
| Sequence      | Sequence number of the PBR                                                                                                                                                                                                                                                                                                |
| VRF ID        | ID of the VRF table associated with an interface                                                                                                                                                                                                                                                                          |
| Route Flags   | Flag bit of PBR:<br>Route Type: type of routes. The value <b>PBR</b> indicates PBR routes while the value <b>Normal</b> indicates common routes.<br>Direct: PBR matching mode. The options include <b>permit</b> and <b>deny</b> .<br>Priority: priority of a PBR route. The options include <b>High</b> and <b>Low</b> . |
| Mode          | Sets the next hop to work in redundancy mode or load balancing mode.                                                                                                                                                                                                                                                      |
| Nexthop Count | Sets the number of next hops. ECMP supports a maximum of 32 next hops.                                                                                                                                                                                                                                                    |
| Nexthop       | Sets the next-hop IPv4 address.                                                                                                                                                                                                                                                                                           |
| Weight        | Sets the next-hop weight value.                                                                                                                                                                                                                                                                                           |
| Ifindex       | Sets the outbound interface index of the next hop.                                                                                                                                                                                                                                                                        |

## 6.15 show ip pbr statistics

Use this command to display the IPv4 PBR forwarded packet count.

**show ip pbr statistics [ interface *if-name* | local ]**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                                 |                                                                                                                                                                                                                                                    |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b>              |                                                                                                                                                                                                                                                    |
| <b>interface</b> <i>if-name</i> | Specifies the interface name. If the interface name is specified, the IPv4 PBR forwarded packet count of this interface is displayed. Otherwise, the IPv4 PBR forwarded packet count of all interfaces where the IPv4 PBR is enabled is displayed. |
| <b>local</b>                    | Displays the IPv4 PBR forwarded packet count on the local interface.                                                                                                                                                                               |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv4 PBR forwarded packet count.

**Examples**

```
Ruijie#show ip pbr statistics
IPv4 Policy-based route statistic
  gigabitEthernet 0/1
    statistics : 10
```

|                         |                |                    |
|-------------------------|----------------|--------------------|
| <b>Related Commands</b> | <b>Command</b> | <b>Description</b> |
|                         | N/A            | N/A                |

**Platform** N/A

**Description**

## 6.16 show ip policy

Use this command to display the interface configured with the policy-based routing and the name of route map applied on the interface.

**show ip policy** [ *route-map-name* ]

|                              |                       |                                    |
|------------------------------|-----------------------|------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b>      | <b>Description</b>                 |
|                              | <i>route-map-name</i> | Indicates the name of a route map. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** You can use this command to verify the current PBR configured in the system.

**Configuration** The following example displays the current PBR configured in the system.

**Examples**

```
Ruijie#show ip policy
Banlance Mode: redundance
Interface      Route map
local          test
FastEthernet 0/0 test
```

|----------------------------------|----------------------------------------------------------|
| <b>ip policy route-map</b>       | Applies the policy-based routing on the interface.       |
| <b>ip local policy route-map</b> | Applies the policy-based routing on the local interface. |

**Platform** N/A

**Description**

### 6.17 show ipv6 pbr bfd

Use this command to display the correlation between the IPv6 policy router and BFD.

**show ipv6 pbr bfd**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the correlation between the IPv6 policy router and BFD.

**Examples**

```
Ruijie# show ipv6 pbr bfd
VRF ID  Ifindex  Host                               State  Refcnt
    0      13  2000::2                           Up      1
```

Field Description

| Field   | Description                                                            |
|---------|------------------------------------------------------------------------|
| VRF ID  | VRF of BFD neighbors correlated with the policy router                 |
| Ifindex | The interface index of BFD neighbors correlated with the policy router |
| Host    | The peer IPv6 address                                                  |

|        |                                                                   |
|--------|-------------------------------------------------------------------|
| State  | Up/Down status of BFD neighbors correlated with the policy router |
| Refcnt | Calculation referred by BFD neighbors                             |

NextHop Count : 1
NextHop[0]    : 10::1
Weight[0]     : 1
Ifindex[0]    : 3
    
```

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PBR IPv4 Route Summay | IPv4 PBR route count.                                                                                                                                                                                                                                                                                                                                                                     |
| Interface             | Interface where IPv4 PBR is enabled.                                                                                                                                                                                                                                                                                                                                                      |
| Sequence              | The PBR serial number.                                                                                                                                                                                                                                                                                                                                                                    |
| ACL                   | The ACL ID used in the match rule.                                                                                                                                                                                                                                                                                                                                                        |
| ACL_CLS               | The ACL type used in the match rule, such as the IP standard ACL.                                                                                                                                                                                                                                                                                                                         |
| Min Length            | The minimum match length.                                                                                                                                                                                                                                                                                                                                                                 |
| Max Length            | The maximum match length.                                                                                                                                                                                                                                                                                                                                                                 |
| VRF ID                | Port associated VRF ID.                                                                                                                                                                                                                                                                                                                                                                   |
| Route Flags           | PBR flag bit:<br>Route Type: "PBR" indicates PBR routes.<br>"Normal" indicates common routes.<br>Direct: PBR matching action, <b>permit</b> or <b>deny</b><br>Priority: PBR priority, <b>High</b> or <b>Low</b><br>Tos_Dscp: Displays whether the <b>tos</b> rule or the <b>dscp</b> rule is configured.<br>Precedence: Displays whether the <b>set ip precedence</b> rule is configured. |
| Mode                  | Specifies the redundancy mode or the load balance mode for the next hop.                                                                                                                                                                                                                                                                                                                  |
| NextHop Count         | Specifies the next hop number. ECMP supports up to 32 next hops.                                                                                                                                                                                                                                                                                                                          |
| NextHop               | Specifies the next hop IP address.                                                                                                                                                                                                                                                                                                                                                        |
| Weight                | Specifies the next hop weight.                                                                                                                                                                                                                                                                                                                                                            |
| Ifindex               | Specifies the outbound interface index corresponding to the next hop                                                                                                                                                                                                                                                                                                                      |

## 6.19 show ipv6 pbr route-map

Use this command to display the IPv6 PBR route-map information.

**show ipv6 pbr route-map** *route-map-name*

| Parameter Description | Parameter             | Description         |
|-----------------------|-----------------------|---------------------|
|                       | <i>route-map-name</i> | The route-map name. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv6 PBR route-map information.

```

Examples Ruijie#show ipv6 pbr route-map rm6
Pbr VRF: GLOBAL, ID: 0
  Forward Mode: redundance
  Forwarding: On

route-map rm6
  route-map index: sequence 10, permit
Match rule:
  ACL ID :      0, ACL CLS: 0, Name: acl6
  Set rule:
    IPv6 Nexthop: 10::1, (VRF Name: , ID: 0), Weight: 0, Flags: 0
    PBR state info ifx: GigabitEthernet 0/0, Connected: true, Track State:
valid, Flags: 0
    
```

| Field           | Description                                                              |
|-----------------|--------------------------------------------------------------------------|
| Pbr VRF         | VRF name and VRF ID.                                                     |
| Forward Mode    | Sets the load balancing mode or to the redundancy mode for the next hop. |
| Forwarding      | Displays whether the IP route forwarding is enabled.                     |
| Route-map index | The serial number and the type of the sub-map.                           |

|                |                                                                                              |
|----------------|----------------------------------------------------------------------------------------------|
| Match rule     | Match rule                                                                                   |
| Set rule       | Set rule.                                                                                    |
| PBR state info | PBR private data information, such as outbound interface and the link state of the next hop. |

**Description**

## 6.20 show ipv6 pbr source- route

Use this command to display the IPv6 source address PBR configuration.

**show ipv6 pbr source-route [ interface *if-name* ]**

**Parameter Description**

| Parameter                       | Description                                                                                                                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface <i>if-name</i></b> | (Optional) Displays the IPv6 source address PBR configuration on the specified interface.<br><br>If the parameter is not configured, the IPv6 source address PBR configuration on all interfaces will be displayed. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv6 source address PBR configuration.

**Examples**

```
Ruijie# show ipv6 pbr source-route
PBR IPv6 Source Route
Interface      : GigabitEthernet 0/1
Sequence      : 10
Source address : 1000::1/64
VRF ID        : 0
Route Flags   :
Route Type    : PBR
Direct       : Permit
Priority      : High
Match_ipaddr : Exist
Mode         : redundance
```

```

Nexthop Count : 1
Nexthop[0] : 1001::2
Weight[0] : 1
Ifindex[0] : 3
    
```

## 6.21 show ipv6 pbr statistics

Use this command to display the IPv6 PBR forwarded packet count.

**show ip pbr statistics [ interface *if-name* | local ]**

| Parameter Description | Parameter                       | Description                                                          |
|-----------------------|---------------------------------|----------------------------------------------------------------------|
|                       | <b>interface</b> <i>if-name</i> |                                                                      |
| <b>local</b>          |                                 | Displays the IPv6 PBR forwarded packet count on the local interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv6 PBR forwarded packet count.

**Examples**

```

Ruijie#show ipv6 pbr statistics
IPv6 Policy-based route statistic
gigabitEthernet 0/1
statistics : 20
    
```

**Description**

## 6.22 show ipv6 policy

Use this command to display which interfaces are configured with IPv6 PBR.

**show ipv6 policy** [ *route-map-name* ]

| Parameter Description | Parameter             | Description                 |
|-----------------------|-----------------------|-----------------------------|
|                       | <i>route-map-name</i> | Name of the PBR router map. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the current PBR applied in the system.

```

Ruijie#show ipv6 policy
Banlance Mode: redundance
Interface          Route map
VLAN 1             RM_for_Vlan_1
VLAN 2             RM_for_Vlan_2
    
```

| Field        | Description                                     |
|--------------|-------------------------------------------------|
| Balance Mode | The current PBR running mode.                   |
| Interface    | The name of interface with PBR applied.         |
| Route map    | The name of route map applied on the interface. |

| Related Commands | Command               | Description                                |
|------------------|-----------------------|--------------------------------------------|
|                  | <b>show route-map</b> | Displays the current configured route map. |

**Platform Description** N/A

## 7 VRF Commands

### 7.1 address-family

Use this command to configure an IPv4 address family or IPv6 address family for a multiprotocol VRF.

**address-family** { *ipv4* | *ipv6* }

| Parameter Description | Parameter   | Description                 |
|-----------------------|-------------|-----------------------------|
|                       | <b>ipv4</b> | Enters IPv4 address family. |
|                       | <b>ipv6</b> | Enters IPv6 address family. |

**Defaults** No IPv4 address family or IPv6 address family is configured for a multiprotocol VRF.

**Command mode** VRF configuration mode

**Usage Guide** This command is applicable only to the multiprotocol VRF.

**Configuration Examples** The following example defines a multiprotocol VRF vrf1 and configures an IPv4 address family.

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#
```

| Related Commands | Command                    | Description                                      |
|------------------|----------------------------|--------------------------------------------------|
|                  | <b>exit-address-family</b> | Exits the VRF address family configuration mode. |
|                  | <b>vrf definition</b>      | Defines a multiprotocol VRF.                     |

**Platform Description** N/A

### 7.2 description

Use this command to configure the VRF description.

**description** *string*

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|               |                                                                         |
|---------------|-------------------------------------------------------------------------|
| <i>string</i> | VRF description character string. The maximum length is 244 characters. |
|---------------|-------------------------------------------------------------------------|

**Defaults** No VRF description is configured by default .

**Command mode** VRF configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example defines a single-protocol IPv4 VRF vrf1 and configure the description to vpn-a.

```
Ruijie(config)#ip vrf definition vrf1
Ruijie(config-vrf)#description vpn-a
```

The following example defines a multiprotocol VRF vrf2 and configure the description to vpn-b.

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#description vpn-b
```

|                  | <b>vrf definition</b> | Defines a multiprotocol VRF.        |

**Platform Description** N/A

### 7.3 exit-address-family

Use this command to exit VRF address family configuration mode.

**exit-address-family**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command mode** VRF address family configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example defines a multiprotocol VRF vrf1 and configures an IPv4 address family.

```
Ruijie(config)#vrf definition vrf1
```

```
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)# exit-address-family
Ruijie(config-vrf)#
```

| <b>Related Commands</b> | Command               | Description                                                                       |
|-------------------------|-----------------------|-----------------------------------------------------------------------------------|
|                         | <b>address-family</b> | Configures an IPv4 address family or IPv6 address family for a multiprotocol VRF. |
|                         | <b>vrf definition</b> | Defines a multiprotocol VRF.                                                      |

**Platform** N/A  
**Description**

## 7.4 ip vrf

Use this command to create a VRF. Use the **no** form of this command to delete a VRF.

```
ip vrf vrf-name
no ip vrf vrf-name
```

| <b>Parameter Description</b> | Parameter       | Description |
|------------------------------|-----------------|-------------|
|                              | <i>vrf-name</i> | VRF name    |

**Defaults** No VRF is configured by default.

**Command mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example creates a VRF.

```
Ruijie(config)# ip vrf redvrf
Ruijie(config-vrf)#
```

| <b>Related Commands</b> | Command | Description |
|-------------------------|---------|-------------|
|                         | N/A     | N/A         |

**Platform** N/A  
**Description**

## 7.5 ip vrf forwarding

Use this command to add an interface or sub-interface to a VRF. Use the **no** form of this command to quit the VRF.

**ip vrf forwarding** *vrf-name*

**no ip vrf forwarding** *vrf-name*

| Parameter Description | Parameter       | Description                                               |
|-----------------------|-----------------|-----------------------------------------------------------|
|                       | <i>vrf-name</i> | Name of the VRF that the interface or sub-interface joins |

**Defaults** By default, the interface does not belong to any VRF.

**Command mode** Interface configuration mode

**Usage Guide** You can bind the interface to the uni-protocol IPv4 VRF without the IPv6 enabled on the interface. On the device supporting the VRF, if the interface is bound to the uni-protocol IPv4 VRF with the IPv6 protocol enabled, the device cannot forward the IPv6 packets received on this interface.

**Configuration Examples** The following example adds an interface or sub-interface to a VRF.

```
Ruijie(config-if-GigabitEthernet 0/0)# ip vrf forwarding redvrf
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 7.6 ip vrf receive

Use this command to import the host and direct-connected route of one interface into the specified VRF routing table. Use the **no** form of this command to remove the imported host and direct-connected route from the VRF.

**ip vrf receive** *vrf-name*

**no ip vrf receive** *vrf-name*

| Parameter Description | Parameter       | Description                                                           |
|-----------------------|-----------------|-----------------------------------------------------------------------|
|                       | <i>vrf-name</i> | Name of the VRF that the host and direct-connected route imported to. |

**Defaults** By default, the host and direct-connected route of the interface are not imported to other VRFs

**Command mode** Interface configuration mode

**Usage Guide** Currently, the **ip vrf receive** command supports the VRF routing based on the PBR. This command is used to import the host with the main and slave addresses and direct-connected route of this interface into the specified VRF routing table. You need to execute this command multiple times to import this host and direct-connected route to multiple VRF routing tables. Unlike the **ip vrf forwarding** command, which does not bind the interface to the VRF and this interface still belongs to the global VRF. Configuring both **ip vrf forwarding** and **ip vrf receive** on an interface is not allowed. If one has been configured, configuring the other one will prompt an error message.

If **ip vrf forwarding** has been configured, configuring **ip vrf receive** will prompt:

```
% Cannot configure 'ip vrf receive' if interface is under a VRF
```

If **ip vrf receive** has been configured, configuring **ip vrf forwarding** will prompt:

```
% Cannot bind interface to a VRF if it has configed 'ip vrf receive'
```

**Configuration Examples** The following example imports the host and direct-connected route of one interface into the specified VRF routing table.

```
Ruijie(config)# interface FastEthernet0/1
Ruijie(config-if)# ip address 192.168.1.2 255.255.255.0
Ruijie(config-if)# ip policy route-map PBR-VRF-SELECTION
Ruijie(config-if)# ip vrf receive VRF_1
Ruijie(config-if)# ip vrf receive VRF_2
Ruijie(config-if)# end
```

**Related Commands**

| Command                  | Description                                         |
|--------------------------|-----------------------------------------------------|
| <b>ip vrf forwarding</b> | Adds the interface to a VRF.                        |
| <b>ip vrf</b>            | Creates a VRF.                                      |
| <b>set vrf</b>           | Sets the VRF in the routing map configuration mode. |

**Platform** N/A

**Description**

## 7.7 maximum routes

Use this command to set the maximum routes limit within the VRF. Use the **no** form of this command to remove the setting.

**maximum routes** *limit* { *warn-threshold* | **warning-only** }

**no maximum routes**

**Parameter**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

| Description           |                                                                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>limit</i>          | The maximum number of routes, in the range from 1 to 4,294,967,295. The routes which exceed the limits will not be added to the core routing table. |
| <i>warn-threshold</i> | The warning will be printed when the threshold is reached. The threshold value is in the range from 1 to 100.                                       |
| <b>warning-only</b>   | After the number of routes reaches <i>limit</i> , the warning will be printed but the routes will be added to the core routing table.               |

**Defaults** N/A

**Command Mode** Single-protocol VRF is configured in VRF configuration mode; multiple-protocol VRF is configured in address family mode.

**Usage Guide** This command is used to set the maximum number of routes for the VRF.

**Configuration Examples** The following example sets the maximum number of routes for vrf1 to 1,000, and enables the device to only print the warning.

```
Ruijie(config)# ip vrf vrf1
Ruijie(config-vrf)# maximum routes 1000 warning-only
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A

**Description**

## 7.8 vrf definition

Use this command to create the multiprotocol VRF.

**vrf definition** *vrf-name*

| Parameter Description | Parameter       | Description |
|-----------------------|-----------------|-------------|
|                       | <i>vrf-name</i> |             |

**Defaults** N/A

**Command mode** Global configuration mode

**Usage Guide** The single-protocol VRF configuration command **ip vrf** cannot be used to edit a multiprotocol VRF; the multiprotocol VRF configuration command **vrf definition** cannot be used to edit a single-protocol

IPv4 VRF.

**Configuration** The following example s creates a multiprotocol VRF *vrf1*.

**Examples**

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#
```

**Related  
Commands**

| Command                    | Description                                                                       |
|----------------------------|-----------------------------------------------------------------------------------|
| <b>description</b>         | Configures the description.                                                       |
| <b>address-family</b>      | Configures an IPv4 address family or IPv6 address family for a multiprotocol VRF. |
| <b>exit-address-family</b> | Exits the VRF address family configuration mode.                                  |
| <b>vrf forwarding</b>      | Binds a network interface to a multiprotocol VRF.                                 |

**Platform** N/A  
**Description**

## 7.9 vrf forwarding

Use this command to bind a network interface to a multiprotocol VRF.

**vrf forwarding** *vrf-name*

**Parameter  
Description**

| Parameter       | Description                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | VRF name, which shall be a multiprotocol VRF instead of a single-protocol VRF that supports IPv4 only. |

**Defaults** The network interface is not bound to any VRF.

**Command  
mode** Interface configuration mode

**Usage Guide** The configuration command **ip vrf forwarding** cannot be used to bind a network interface to a multiprotocol VRF; the configuration command **vrf forwarding** cannot be used to bind a network interface to a single-protocol IPv4 VRF.

An interface cannot be bound to a multiprotocol VRF that is not configured with any address family. To bind a network interface to a multiprotocol VRF, you should delete the existing IPv4 addresses, VRRP IPv4 addresses, IPv6 addresses and VRRP IPv6 addresses, and disable IPv6 on the interface. When a network interface is bound to a multiprotocol VRF, no IPv4 address or VRRP IPv4 address should be configured for the interface if no IPv4 address family is configured for the VRF. You should configure an IPv4 address family for the VRF before configuring an IPv4 address and VRRP IPv4 address for the interface.

When a network interface is bound to a multiprotocol VRF, no IPv6 address or VRRP IPv6 address should be configured for the interface if no IPv6 address family is configured for the VRF. You should configure an IPv6 address family for the VRF before configuring an IPv6 address and VRRP IPv6 address for the interface.

If you delete a multiprotocol VRF's IPv4 address family, you should delete the IPv4 addresses and VRRP IPv4 addresses of all network interfaces bound to the VRF, and delete the IPv4 static routes whose routing VRF or next-hop VRF is that VRF. Likewise, if you delete a multiprotocol VRF's IPv6 address family, you should delete the IPv4 addresses and VRRP IPv6 addresses of all network interfaces bound to the VRF, disable IPv6 on the interfaces, and delete the IPv6 static routes whose routing VRF or next-hop VRF is that VRF.

**Configuration** The following example binds the interface VLAN 1 to a multiprotocol VRF vrf1.

**Examples**

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#address-family ipv4
Ruijie(config-vrf-af)#exit-address-family
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family

Ruijie(config-vrf)#interface vlan 1
Ruijie(config-if)#vrf forwarding vrf1
Ruijie(config-if)#ip address 1.1.1.1 255.255.255.0
Ruijie(config-if)#ipv6 address 1000::1/64
```

**Related  
Commands**

| Command               | Description                  |
|-----------------------|------------------------------|
| <b>vrf definition</b> | Defines a multiprotocol VRF. |

**Platform** N/A

**Description**

## 7.10 vrf receive

Use this command to add the local host's route and direct route with the interface's IPv4/v6 address to the routing table of the specified VRF.

**vrf receive** *vrf-name*

**Parameter  
Description**

| Parameter       | Description                                                                          |
|-----------------|--------------------------------------------------------------------------------------|
| <i>vrf-name</i> | VRF name, which should be a multiprotocol VRF instead of a single-protocol IPv4 VRF. |

**Defaults** N/A

**Command** Interface configuration mode

**mode**

**Usage Guide** This command is not used to bind an interface to a VRF, and the interface is still a global interface. If the administrator needs to use PBR to choose VRF, the **vrf receive** command should be configured on the interfaces where PBR is applied for each selected VRF.

When an IPv4 address family is configured for a multiprotocol VRF, the local host's route and direct route with the interface's IPv4 address is added to the IPv4 routing table of the specified VRF, and the local host's route with the IPv4 address of the master VRRP group on the interface is added to the IPv4 routing table of the specified VRF. When an IPv6 address family is configured for a multiprotocol VRF, the local host's route and direct route with the interface's IPv6 address is added to the IPv6 routing table of the specified VRF, and the local host's route with the IPv6 address of the master VRRP group on the interface is added to the IPv6 routing table of the specified VRF.

The **ip vrf forwarding** and **vrf receive** commands are mutually exclusive on an interface, and so are the **vrf forwarding** and **vrf receive** commands. If both commands are configured on an interface, an error message will be shown.

If the **ip vrf forwarding** or **vrf forwarding** command is configured first, and then the **vrf receive** command is configured, the following message will be displayed:

```
% Cannot configure 'vrf receive' if interface is under a VRF
```

If the **vrf receive** command is configured first, and then the **ip vrf forwarding** or **vrf forwarding** command is configured, the following message will be displayed:

```
% Cannot configure 'vrf forwarding vrf2' on this interface, please delete 'ip vrf receive' and 'vrf receive' first.
```

**Configuration** The following example selects a VRF using IPv6 PBR on VLAN 1.

**Examples**

```
Ruijie(config)#vrf definition vrf1
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family

Ruijie(config-vrf)#vrf definition vrf2
Ruijie(config-vrf)#address-family ipv6
Ruijie(config-vrf-af)#exit-address-family

Ruijie(config-vrf)#route-map pbr-vrf-selection permit 10
Ruijie(config-route-map)#match ipv6 address acl1
Ruijie(config-route-map)#set vrf vrf1
Ruijie(config-route-map)#route-map pbr-vrf-selection permit 20
Ruijie(config-route-map)#set vrf vrf2

Ruijie(config-route-map)#interface vlan 1
Ruijie(config-if)#ipv6 policy route-map pbr-vrf-selection
Ruijie(config-if)#ipv6 address 1000::1/64
Ruijie(config-if)#vrf receive vrf1
Ruijie(config-if)#vrf receive vrf2
```

**Related  
Commands**

| <b>Command</b>        | <b>Description</b>                                                                |
|-----------------------|-----------------------------------------------------------------------------------|
| <b>vrf definition</b> | Defines a multiprotocol VRF.                                                      |
| <b>address-family</b> | Configures an IPv4 address family or IPv6 address family for a multiprotocol VRF. |
| <b>set vrf</b>        | Configures a VRF in the route map configuration mode.                             |

**Platform  
Description**

N/A

## 7.11 show ip vrf

Use this command to display the VRF information.

**show ip vrf [ brief | detail | interfaces ]**

### Parameter Description

| Parameter         | Description                                                    |
|-------------------|----------------------------------------------------------------|
| <b>brief</b>      | (Optional) Displays the VRF information in brief.              |
| <b>detail</b>     | (Optional) Displays the VRF information in detail.             |
| <b>interfaces</b> | (Optional) Displays the VRF's interface information in detail. |

### Defaults

All VRF information is displayed without parameter specified.

### Command mode

Privileged EXEC mode

### Usage Guide

Use this command to display the VRF information, which can be divided into two levels:

Use the keyword **brief** to display the information in brief.

Use the keyword **detail** to display the information in detail.

Use the keyword **interfaces** to display the VRF's interface information.

### Configuration

The following example displays the VRF information.

### Examples

```
Ruijie#show ip vrf
Name                    Interfaces
aaa                    GigabitEthernet 0/0
                        GigabitEthernet 0/1
```

### Related Commands

### Description

## 7.12 show vrf

Use this command to display the VRF configuration (including the single-protocol VRF and the multiple-protocol VRF).

**show vrf [ ipv4 | ipv6 | brief | count | detail ]**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|               |                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>   | Displays the brief VRF (the single-protocol VRF) information of the IPv4 address family.             |
| <b>Ipv6</b>   | Displays the VRF brief information of the IPv6 address family.                                       |
| <b>brief</b>  | Displays the brief VRF (including the single-protocol VRF and the multiple-protocol) information.    |
| <b>count</b>  | Displays the capacity of VRF and its current value.                                                  |
| <b>detail</b> | Displays the detailed VRF (including the single-protocol VRF and the multiple-protocol) information. |

**Defaults** N/A

**Command mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays brief information about all VRF.

**Examples**

```
Ruijie#show vrf
  Name          Default RD      Protocols  Interfaces
  ---          -
  aaa           <not set>      ipv4
  aab           <not set>
  bbb           <not set>      ipv6
  ccc           <not set>      ipv4,ipv6  V11
```

:

| Field      | Description                                                                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name       | VRF name.                                                                                                                                                            |
| Default RD | Default RD of the VRF.                                                                                                                                               |
| Protocol   | The address family of the VRF. IPv4 indicates the VRF is enabled in the IPv4 address family mode; ipv6 indicates the VRF is enabled in the IPv6 address family mode. |
| Interfaces | The interface list of the VRF. The interface where the [ip] vrf forwarding command has been configured will be displayed on that list.                               |

## 8 RIPng Commands

### 8.1 clear ipv6 rip

Use this command to clear the RIPng routes.

**clear ipv6 rip**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** None

**Command mode** Privileged EXEC mode

**Usage Guide** Running this command removes all RIPng routes and this operation may have great impact on the RIPng protocol. This command should be used with caution.

**Configuration Examples** The following example clears the RIPng routes:

```
Ruijie# clear ipv6 rip
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 8.2 default-metric

Use this command to configure the default metric for RIPng. Use the **no** form of this command to restore the default value.

**default-metric metric**

**no default-metric**

| Parameter Description | Parameter     | Description                                                                                                                                 |
|-----------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>metric</i> | Sets the default metric value. The valid range is from 1 to 16. The route is unreachable if the metric value is larger than or equal to 16. |

**Defaults** The default value is 1.

**Command mode** Routing process configuration mode.

**Usage Guide** This command shall be used with the **redistribute** command. When redistributing the route from one route process to RIPng, due to the incompatibility of metric calculation mechanisms of different routing protocols, it fails to translate the routing metric values. To this end, the RIPng metric value shall be defined when translating the metric values. If there is no defined metric value, use the **default-metric** command to define one; and the defined metric value will overwrite the value of the **default-metric** command. By default, the **default-metric** value is 1.

**Configuration Examples** The following example shows how to set the RIPng metric value as 3 when redistributing OSPF process 100:

```
Ruijie(config-router)# default-metric 3
Ruijie(config-router)# redistribute ospf 100
```

**Related Commands**

| Command             | Description                                                            |
|---------------------|------------------------------------------------------------------------|
| <b>redistribute</b> | Redistributes the route from one route domain to another route domain. |

**Platform Description** N/A

## 8.3 distance

Use this command to set the administrative distance of RIPng. Use the **no** form of this command to restore the default value.

**distance** *distance*  
**no distance**

**Parameter Description**

| Parameter       | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| <i>distance</i> | Sets the RIPng administrative distance. The range is from 1 to 254. |

**Defaults** The default distance is 120

**Command mode** Routing process configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example shows how to set the RIPng administrative distance as 160:

```
Ruijie(config)# ipv6 router rip
```

```
Ruijie(config-router)# distance 160
```

**Related  
Commands**

**Description**

## 8.4 distribute-list

Use this command to filter the in/out route in the prefix list. Use the **no** form of this command to remove route filtering.

**distribute-list prefix-list** *prefix-list-name* { **in** | **out** } [ *interface-type interface-name* ]

**no distribute-list prefix-list** *prefix-list-name* { **in** | **out** } [ *interface-type interface-name* ]

**Parameter  
Description**

| Parameter                                      | Description                                                        |
|------------------------------------------------|--------------------------------------------------------------------|
| <b>prefix-list</b> <i>prefix-list-name</i>     | Name of the prefix list which is used to filter the route.         |
| <b>in</b>   <b>out</b>                         | Filters the in or out route in the distribute list.                |
| <i>interface-type</i><br><i>interface-name</i> | (Optional) Applies the distribute list to the specified interface. |

**Defaults**

By default, no distribute list is defined.

**Command  
mode**

Routing process configuration mode.

**Usage Guide**

This command is used to configure the route distribution control list to filter all update routes for the purpose of refusing to receive or send the specified routes. If the interface is not specified, the update routes on all interfaces are filtered.

**Configuration**

The following example shows how to filter the received update route on the interface eth0 (only those update routes within the **prefix-list** *allowpre* prefix list range can be received)

**Examples**

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# distribute-list prefix-list allowpre in eth0
```

**Related  
Commands**

**Description**

## 8.5 graceful-restart

Use this command to configure the graceful restart (GR) function for the RIPng process.

**graceful-restart** [ **grace-period** *grace-period* ]

Use the **no** form of this command restore the default configurations.

**no graceful-restart** [ **grace-period** ]

### Parameter Description

| Parameter               | Description                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>graceful-restart</b> | Enables the GR function.                                                                                                                          |
| <b>grace-period</b>     | Displays the configured grace period.                                                                                                             |
| <i>grace-period</i>     | Indicates the configured GR period, ranging from 1 to 1800 seconds.<br>The default value is the smaller between twice of the update time and 60s. |

### Defaults

The GR function is enabled by default.

### Command Mode

Routing process configuration mode

### Default Level

14

### Usage Guide

The GR function is configured based on RIPng instances. Different parameters can be configured for different RIPng instances as required.

The GR period indicates the maximum duration from RIPng restart to RIPng GR completion. In this time period, the forwarding table before restart is used and the RIPng route is restored to the status before restart. After the GR period expires, the RIPng process exits the GR status and the common RIPng operation is performed.

The **graceful-restart grace-period** command allows a user to modify the GR period in explicit mode. Note that GR is completed and the RIPng route is updated once before the RIPng route becomes invalid. If the GR period is improperly set, continuous data forwarding in the GR process cannot be ensured. A typical case is as follows:

If the GR period is greater than the invalid time of the neighbor route, GR is not completed before the route becomes invalid and the route is not advertised to the neighbor again. The neighbor route stops forwarding data after the route becomes invalid, resulting in data forwarding interruption. Therefore, unless otherwise specified, it is not recommended to adjust the GR period. If the GR period needs to be configured, check configuration of the **timers** command to ensure that the GR period value is greater than the route update time and smaller than the route invalid time.

When GR is performed for the RIPng process, ensure that the network environment is stable.

### Configuration Examples

The following example enables the GR function for the RIPng process and configures the GR period.

#### Examples

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# graceful-restart grace-period 90
```

|                             |                                                                                                                            |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>Verification</b>         | Run the <b>show ipv6 rip</b> command to check whether the GR function is configured and query the configured grace period. |
| <b>Prompts</b>              | N/A                                                                                                                        |
| <b>Common Errors</b>        | N/A                                                                                                                        |
| <b>Platform Description</b> | N/A                                                                                                                        |

## 8.6 ipv6 rip default-information

Use this command to generate a default IPv6 route to the RIPng. Use the **no** form of this command to remove the default route.

**ipv6 rip default-information** { **only** | **originate** } [ **metric** *metric-value* ]

**no ipv6 rip default-information**

### Parameter Description

| Parameter                         | Description                                                                                            |
|-----------------------------------|--------------------------------------------------------------------------------------------------------|
| <b>only</b>                       | Advertises the IPv6 default route only.                                                                |
| <b>originate</b>                  | Advertises both of the IPv6 default route and other routes.                                            |
| <b>metric</b> <i>metric-value</i> | Sets the metric value for the default route. The valid range is from 1 to 15. The default metric is 1. |

**Defaults** By default, no default route is configured.

**Command mode** Interface configuration mode

**Usage Guide** With this command configured on an interface, the interface advertises an IPv6 default route and the route itself is not to join the device route forwarding table and the RIPng route database. To avoid the route loop, once this command has been configured on the interface, RIPng refuses to receive the default route update message advertised from the neighbor.

**Configuration Examples** The following example shows how to create a default route to the RIPng routing process on the interface ethernet0/0 and enable this interface to advertise the default route only:

```
Ruijie(config)# interface ethernet 0/0
Ruijie(config-if)# ipv6 rip default-information only
```

### Related Commands

| Command                       | Description                                |
|-------------------------------|--------------------------------------------|
| <b>show ipv6 rip</b>          | Displays the RIPng process and statistics. |
| <b>show ipv6 rip database</b> | Displays the RIPng route.                  |

**Platform** N/A

**Description**

## 8.7 ipv6 rip enable

Use this command to enable the RIPng on the interface. Use the **no** form of this command to disable RIPng on the interface.

**ipv6 rip enable**

**no ipv6 rip enable**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** It is disabled by default.

**Command mode** Interface configuration mode.

**Usage Guide** This command is used to add the RIPng interface. Before this command is configured, if the RIPng is not enabled, use this command to enable the RIPng automatically.

**Configuration Examples** The following example shows how to enable the RIPng on the interface 0/0:

```
Ruijie(config)# interface ethernet 0/0
Ruijie(config-if)# ipv6 rip enable
```

## 8.8 ipv6 rip metric-offset

Use this command to set the interface metric value. Use the **no** form of this command to remove the metric configurations.

**ipv6 rip metric-offset *value***

**no ipv6 rip metric-offset**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|              |                                                                                    |
|--------------|------------------------------------------------------------------------------------|
| <i>value</i> | Sets the interface metric value on the interface. The valid range is from 1 to 16. |
|--------------|------------------------------------------------------------------------------------|

**Defaults** The default value is 1.

**Command mode** Interface configuration mode.

**Usage Guide** Before the route is added to the routing list, the interface metric value shall be upon the route metric. To this end, the interface metric value influences the route usage.

**Configuration** The following example shows how to set the metric value of the interface Ethernet 0/1 as 5:

**Examples**

```
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if)# ipv6 rip metric-offset 5
```

**Related Commands**

| N/A     | N/A         |

**Platform Description** N/A

## 8.9 ipv6 rip subvlan

Use this command to enable RIPng on super VLANs. Use the **no** form of this command to restore the default setting.

**ipv6 rip subvlan [all | vid]**

**no ipv6 rip subvlan**

**Parameter Description**

| Parameter  | Description                                                     |
|------------|-----------------------------------------------------------------|
| all        | Indicates that packets are allowed to be sent to all sub VLANs. |
| <i>vid</i> | Specifies the sub VLAN ID. The value ranges from 1 to 4094.     |

**Defaults** The default setting takes effect only on super VLANs with RIPng disabled.

**Command Mode** Interface configuration mode.

**Usage Guide** In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when RIPng multicast packets are sent over a super VLAN containing multiple sub VLANs, the RIPng multicast packets are replicated multiple times, and the device processing capability is insufficient. As a result, a large number of packets are discarded, causing the neighbor down error. In most scenarios, the RIPng function does not need to be enabled on a super VLAN. Therefore, the RIPng function is disabled by default. However, in some scenarios, the RIPng function must be run on the super VLAN, but packets only need to be sent to one sub VLAN. In this case, run this command to specify a particular sub VLAN. You must be cautious in configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor down error.

**Configuration** The following example sends the RIPng multicast packets to sub VLAN 1024 of super VLAN 300.

**Examples**

```
Ruijie(config)# interface vlan 300
Ruijie(config-if-VLAN 300)# ipv6 rip subvlan 1024
```

## 8.10 ipv6 router rip

Use this command to create the RIPng process and enter routing process configuration mode. Use the **no** form of this command to remove the RIPng process.

**ipv6 router rip**  
**no ipv6 router rip**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** No RIPng process is configured by default.

**Command mode** Global configuration mode.

**Usage Guide** N/A.

**Configuration Examples** The following example shows how to create the RIPng process and enter routing process configuration mode:

```
Ruijie(config)# ipv6 router rip
```

| Related Commands | Command                | Description                                   |
|------------------|------------------------|-----------------------------------------------|
|                  | <b>ipv6 rip enable</b> | Enables the RIPng on the specified interface. |

**Platform** N/A  
**Description**

## 8.11 passive-interface

Use this command to disable the interface to send update packets. Use the **no** form of this command to enable the interface to send update packets.

**passive-interface** { **default** | *interface-type interface-num* }

**no passive-interface** { **default** | *interface-type interface-num* }

| Parameter Description | Parameter                           | Description                                 |
|-----------------------|-------------------------------------|---------------------------------------------|
|                       | <b>default</b>                      | Enables the passive mode on all interfaces. |
|                       | <i>interface-type interface-num</i> | Interface type and interface number.        |

**Defaults** No passive interface is configured by default.

**Command mode** Routing process configuration mode.

**Usage Guide** You can use the **passive-interface default** command to enable the passive mode on all interfaces. Then ,use the **no passive-interface interface-type interface-num** command to remove the specified interface from the passive mode.

**Configuration Examples** The following example shows how to enable the passive mode on all interfaces and remove interface ethernet 0/0 from the passive mode:

```
Ruijie(config-router)# passive-interface default
Ruijie(config-router)# no passive-interface ethernet 0/0
```

**Description**

## 8.12 redistribute

Use this command to redistribute the route of other routing protocols to RIPng. Use the **no** form of this command to remove the redistribution configuration.

**redistribute** { **bgp** | **connected** | **isis** [*area-tag*] | **ospf** *process-id* | **static**} [ **metric** *metric-value* | **route-map** *route-map-name* ]

**no redistribute** { **bgp** | **connected** | **isis** [*area-tag*] | **ospf** *process-id* | **static**} [ **metric** *metric-value* |

**route-map** *route-map-name* ]

**Parameter  
Description**

| Parameter                              | Description                                                                                                                        |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>bgp</b>                             | Redistributes the BGP routes to RIPng.                                                                                             |
| <b>connected</b>                       | Redistributes the connected routes to RIPng.                                                                                       |
| <b>isis</b> [ <i>area-tag</i> ]        | Redistributes the ISIS routes to RIPng.<br><i>area-tag</i> indicates the ISIS process number.                                      |
| <b>ospf</b> <i>process-id</i>          | Redistributes the OSPF routes to RIPng.<br><i>process-id</i> indicates the OSPF process number, and the range is from 1 to 65,535. |
| <b>static</b>                          | Redistributes the static routes to RIPng.                                                                                          |
| <b>metric</b> <i>metric-value</i>      | (Optional) Sets the metric value for the route redistributed to RIPng.                                                             |
| <b>route-map</b> <i>route-map-name</i> | (Optional) Sets the redistribution route filtering.                                                                                |

**Defaults**

By default, the routes of other routing protocols are not redistributed.

If the **default-metric** command is not configured, the default metric value is 1;

By default, the **route-map** is not configured;

By default, all sub-type routes in the specified routing process are redistributed.

**Command  
mode**

Routing process configuration mode.

**Usage Guide**

This command is used to redistribute the external routes to RIPng.

It is unnecessary to transform the metric of one routing protocol into another routing protocol in the process of the route redistribution, for the metric calculation methods of the different routing protocols are different. The RIP and OSPF metric calculations are incomparable for the reason that the RIP metric calculation is hop-based while the OSPF one is bandwidth-based.

The instance, from where the routing information is redistributed to the RIPng, must be specified in the process of configuring the multi-instance protocol redistribution.

**Configuration  
Examples**

The following example shows how to redistribute the static route, use the route map *mymap* to filter and set the metric value as 8:

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# redistribute static route-map
mymap metric 8
```

**Description**

### 8.13 show ipv6 rip

Use this command to show the parameters and each statistical information of the RIPng routing protocol process.

**show ipv6 rip**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command mode** Privileged EXEC mode or user mode.

**Usage Guide** N/A

```

Configuration Ruijie# show ipv6 rip
Examples Routing Protocol is "RIPng"
Sending updates every 10 seconds with +/-50%, next due in 8 seconds
Timeout after 30 seconds, garbage collect after 60 seconds
Outgoing update filter list for all interface is:
distribute-list prefix aa out
Incoming update filter list for all interface is: not set
Default redistribution metric is 1
Default distance is 120
Redistribution:
Redistributing protocol connected route-map rm
Redistributing protocol static
Redistributing protocol ospf 1
Default version control: send version 1, receive version 1
Interface          Send  Recv
VLAN 1              1    1
Loopback 1          1    1
Routing Information Sources:
None
    
```

**Description**

## 8.15 split-horizon

Use the **split-horizon** command to enable the RIPng split-horizon function in routing process configuration mode. Use the **no** form of this command to disable this function. Use the **split-horizon poisoned-reverse** command to enable the RIPng poisoned reverse horizontal split function in routing process configuration mode. Use the **no** form of this command to disable this function.

**split-horizon [ poisoned-reverse ]**

**no split-horizon [ poisoned-reverse ]**

| Parameter Description | Parameter               | Description                                               |
|-----------------------|-------------------------|-----------------------------------------------------------|
|                       | <b>poisoned-reverse</b> | (Optional) Enables the poisoned-reverse horizontal split. |

**Defaults** RIPng split horizon is enabled by default.

**Command mode** Routing process configuration mode.

**Usage Guide** In the process of packet updating, split-horizon function prevents some routing information from being advertised through the interface learning those routing information. The poisoned reverse horizontal split function advertises some routing information to the interface learning those routing information, and the metric value is set as 16. The RIPng routing protocol belongs to the distance vector routing protocol, so the horizontal split shall be noticed in the actual application. You can use the **show ipv6 rip** command to determine whether the RIPng split-horizon function is enabled or not.

**Configuration** The following example shows how to disable the RIPng horizontal split:

**Examples**

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# no split-horizon
```

**Description**

## 8.16 timers

Use this command to adjust the RIPng timer. Use the **no** form of this command to restore the default settings.

**timers update invalid flush**

**no timers**

| Parameter Description | Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>update</i>  | Sets the routing update time, in seconds. The update parameter defines the period of sending the routing update packets by the device. The invalid and flush parameter reset once the update packets are received.                                                                                                                                                                                                                                              |
|                       | <i>invalid</i> | Sets the routing invalid time, in seconds, starting from receiving the last valid update packet. The invalid parameter defines the invalid time for the un-updated routing in the routing list. The routing invalid time shall be three times larger than the routing update time. The routing will be invalid if no update packets are received within the routing invalid time, and it will reset if the update packets are received within the invalid time. |
|                       | <i>flush</i>   | Sets the routing flush time, in seconds, starting from RIPng entering to invalid state. The invalid routing will be removed from the routing list if the flush time expires.                                                                                                                                                                                                                                                                                    |

**Defaults** The default update time is 30 seconds; the default invalid time is 180 seconds; and the default flush time is 120 seconds.

**Command mode** Routing process configuration mode.

**Usage Guide** Adjusting the above time may speed up the RIPng convergence time and the troubleshooting time. The RIPng time must be consistent for the devices connecting to the same network. You are not recommended to adjust the RIP time, except for the specific requirement.

Use the **show ipv6 rip** command to view the current RIPng time parameter setting.

In the low-speed link, with the short time configured, large amount of the update packets consumes a lot of bandwidth. Generally, the short time can be configured in the Ethernet or 2Mbps-higher line to shorten the convergence time of the network routing.

**Configuration Examples** The following example shows how to send the RIP update packets every 10 seconds. The routing will be invalid if no update packets are received within 30 seconds, and the routing will be removed after being invalid for 90 seconds.

```
Ruijie(config)# ipv6 router rip
Ruijie(config-router)# timers 10 30 90
```

## 9 NSM Commands

### 9.1 clear ip route

Use this command to clear the route cache.

```
clear ip route [ vrf vrf_name ] { * | network [ netmask ] | }
```

|                          | Parameter           | Description                                                                                                                                                                          |
|--------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter<br>Description | <i>vrf vrf_name</i> | (Optional) Specifies the route cache of the specified VRF instance. If no VRF is specified, the route cache of all VRF instances is cleared.                                         |
|                          | *                   | Clears all route cache.                                                                                                                                                              |
|                          | <i>network</i>      | Specifies the route cache of the network or subnet.                                                                                                                                  |
|                          | <i>netmask</i>      | (Optional) Subnet mask. If no subnet mask is specified, the longest match principle is used when you match <i>network</i> with the route. The cache of the longest match is cleared. |

#### Command

**Mode** Privileged EXEC mode

**Usage** Clearing route cache clears the corresponding routes and triggers the routing protocol relearning.

**Guide** Please note that clearing all route cache leads to temporary network disconnection.

**Examples** The following example clears the cache of the route which is the longest match with IP address 192.168.12.0.

```
clear ip route 192.168.12.0
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

#### Platform

**Description** This command is not supported on 2-layer devices.

### 9.2 ip default-network

Use this command to configure the default network globally. Use the **no** or **default** form of this command to restore the default setting.

```
ip default-network network
```

```
no ip default-network network
```

```
default ip default-network network
```

| Parameter   | Parameter      | Description     |
|-------------|----------------|-----------------|
| Description | <i>network</i> | Default network |

**Defaults** The default is 0.0.0.0/0.

**Command Mode** Global configuration mode

**Usage** The goal of this command is to generate the default route. The default network must be reachable in the routing table, but not the directly connected network.

**Guide** The default network always starts with an asterisk ("\*"), indicating that it is the candidate of the default route. If there is connected route and the route without the next hop in the default network, the default route must be a static route.

The following example sets 192.168.100.0 as the default network. Since the static route to the network is configured, the device will automatically generate a default route.

**Examples**

```
ip route 192.168.100.0 255.255.255.0 serial 0/1
ip default-network 192.168.100.0
```

The following example sets 200.200.200.0 as the default network. The route becomes the default one only when it is available in the routing table.

```
ip default-network 200.200.200.0
```

| Related  | Command              | Description                 |
|----------|----------------------|-----------------------------|
| Commands | <b>show ip route</b> | Displays the routing table. |

### 9.3 ip fast-reroute route-map

Use this command to enable static fast reroute. Use the **no** or **default** form of this command to restore the default setting.

**ip fast-reroute** [ **vrf** *vrf-name* ] **static route-map** *route-map-name*

**no ip fast-reroute** [ **vrf** *vrf-name* ]

**default ip fast-reroute** [ **vrf** *vrf-name* ] **route-map**

| Parameter   | Parameter                              | Description  |
|-------------|----------------------------------------|--------------|
| Description | <b>vrf</b> <i>vrf-name</i>             | VRF          |
|             | <b>route-map</b> <i>route-map-name</i> | Route map    |
|             | <b>static</b>                          | Backup route |

**Default** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage guideline** Fast reroute provides an active next-hop and a backup one. If the active next-hop fails, the backup next-hop is used for forwarding.

To enhance the performance of fast reroute, enable the BFD detection function for the active next-hop. For interfaces that are up or down, to shorten the interruption time of fast reroute, configure **carrier-delay 0** in the interface configuration mode of the active outbound interface to optimize the performance.

For static fast reroute, if the active next-hop fails, the backup next-hop is used for forwarding.

**Examples** The following example sets the backup next-hop of all static routes to 192.168.1.2 through the outbound interface of GigabitEthernet 0/1.

```
Ruijie(config)# route-map fast-reroute
Ruijie(config-route-map)# set fast-reroute backup-nexthop GigabitEthernet 0/1
192.168.1.2
Ruijie(config-route-map)# exit
Ruijie(config)# ip fast-reroute static route-map fast-reroute
```

| Related command | Command             | Description                   |
|-----------------|---------------------|-------------------------------|
|                 | <b>fast-reroute</b> | Configures OSPF fast reroute. |

**Platform Description** This command is not supported on 2-layer devices.

## 9.4 ip route

Use this command to configure a static route. Use the **no** or **default** form of this command to restore the default setting.

**ip route** [ vrf vrf\_name ] network net-mask { ip-address | interface [ ip-address ] } [ distance ] [ tag tag ] [ permanent | {track object-number | arp} ] [ weight number ] [description description-text] [ disabled | enabled ] [ global ]

**no ip route** [ vrf vrf\_name ] network net-mask { ip-address | interface [ ip-address ] } [ distance ]

**no ip route** [ vrf vrf\_name ] all

**default ip route** [ vrf vrf\_name ] network net-mask { ip-address | interface [ ip-address ] } [ distance ]

**default ip route** [ vrf vrf\_name ] all

| Parameter           | Description                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------|
| <b>vrf vrf_name</b> | Name of the VRF, which can be the single protocol IPv4 VRF or configured IPv4 address family multi-protocol VRF. |
| <b>network</b>      | Network address of the destination                                                                               |
| <b>net-mask</b>     | Mask of the destination                                                                                          |
| <b>ip-address</b>   | The next hop IP address of the static route                                                                      |
| <b>interface</b>    | (Optional) The next hop egress of the static route                                                               |
| <b>distance</b>     | (Optional) The administrative distance of the static route                                                       |

|                                            |                                                                                                                                                                                 |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>tag</i>                                 | (Optional) The tag of the static route                                                                                                                                          |
| <b>permanent</b>                           | (Optional) Permanent route ID                                                                                                                                                   |
| <b>track</b> <i>object-number</i>          | (Optional) Indicates correlation with Track. <i>object-number</i> indicates the ID of the track object. By default, the static route is not correlated with the Track function. |
| <b>weight</b> <i>number</i>                | (Optional) Indicates the weight of the static route. The weight is 1 by default.                                                                                                |
| <b>description</b> <i>description-text</i> | (Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.                |
| <b>disabled/enabled</b>                    | (Optional) Indicates the enable flag of the static route. The flag is enabled by default.                                                                                       |
| <b>global</b>                              | (Optional) Indicates that the next hop belongs to a global VRF. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> .                       |

**Defaults** No static route is configured by default.

**Command Mode** Global configuration mode

The default administrative distance of the static route is 1. Setting the administrative distance allows the learnt dynamic route to overwrite the static route. Setting the administrative distance of the static route can enable route backup, which is called floating route in this case. For example, the administrative distance of the OSPF is 110. You can set its administrative distance to 125. Then the data can switch over the static route when the route running OSPF fails.

You can specify the VRF that the static route belongs to. The default weight of the static route is 1. To view the static route of non default weight, execute the show ip route weight command. The parameter weight is used to enable WCMP. When there are load-balanced routes to the destination, the device assigns data flows by their weights. The higher the weight of a route is, the more data flow the route carries. WCMP limit is generally 32 for routers. However, WCMP limit varies by switch models for their chipsets support different weights. When the sum of the weights of load balanced routes is beyond this weight limit, the excessive ones will not take effect.

**Usage Guide** Enablement/disablement shows the state of the static route. Disablement means the static route is not used for forwarding. The forwarding table used the permanent route until administrator deletes it. Association between a static route and an ARP object can be specified. When association between a static route and an ARP object is configured and the ARP object corresponding to the next hop and egress of the route does not exist, the static route does not take effect. When the ARP object corresponding to the next hop and egress of the route exists, the static route takes effect based on another status. Association between a static route and an ARP object cannot be used for routes with the permanent attribute.

**Examples** The following example adds a static route to the destination network of 172.16.100.0/24 whose next

hop is 192.168.12.1 and administrative distance is 15.

```
ip route 172.16.199.0 255.255.255.0 192.168.12.1 155
```

If the static route has not a specific interface, data flows may be sent through other interface in case of interface failure. The following example configures data flows to be sent through fastethernet 0/0 to the destination network of 172.16.100.0/24.

```
ip route 172.16.199.0 255.255.255.0 fastethernet 0/0 192.168.12.1
```

## 9.5 ip route static bfd

Use this command to correlate the static route with BFD. Use the **no** or **default** form of this command to restore the default setting.

**ip route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**no ip route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**default ip route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

Use this command to correlate the static route with BFD. Use the **no** or **default** form of this command to restore the default setting.

#### Parameter Description

| Parameter                              | Description                                                                                                                                                                                                 |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i>             | (Optional) Specifies the VRF name of the static route. By default, it is global VRF,                                                                                                                        |
| <i>interface-type interface-number</i> | Interface type and interface number.                                                                                                                                                                        |
| <i>gateway</i>                         | Specifies the gateway IP address, that is, the BFD neighbor IP address. If the next hop of the static route is the neighbor, the BFD will detect whether this neighbor is reachable.                        |
| <b>source</b> <i>ip-address</i>        | (Optional) The source IP address of the BFD session. If the neighbor device is multi hops away, you should specify the source IP address for the BFD session. No source IP address is specified by default. |

**Defaults** The static address is not correlated with BFD by default.

**Command Mode** Global configuration mode

**Usage Guide**  Please make sure the BFD session parameters have been configured before executing this command.

**Examples** The following example correlates the static route with BFD, and detects the reachability of path to the

```
neighbor 172.16.0.2.
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# no switchport // No need to perform
this command on the router.
Ruijie(config-if-GigabitEthernet 0/1)# ip address 172.16.0.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# bfd interval 50 min_rx 50 multiplier
3
Ruijie(config-if-GigabitEthernet 0/1)#exit
Ruijie(config)# ip route static bfd GigabitEthernet 0/1 172.16.0.2
Ruijie(config)# ip route 10.0.0.0 255.0.0.0 GigabitEthernet 0/1 172.16.0.2
```

## 9.6 ip route static inter-vrf

Use this command to enable packets to be forwarded over VRF instances through the static route. Use the **no** or **default** form of this command to disable this function.

**ip route static inter-vrf**

**no ip route static inter-vrf**

**default ip route static inter-vrf**

Use this command to enable packets to be forwarded over VRF instances through the static route. Use the **no** or **default** form of this command to disable this function.

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** Global configuration mode

**Usage Guide** If the **no** form of this command is executed, packets are unable to be forwarded over VRF instances through the static route. If this command is executed and you want to use the **no** form of this command to disable such function, the following information will be displayed.

```
*Aug 7 10:58:34: %NSM-6-ROUTESACROSSVRF: Un-installing route [x.x.x.x/8] from
global routing table with outgoing interface x/x.
```

**Examples** The following example disables packets to be forwarded over VRF instances through the static route.

```
Ruijie(config)# no ip route static inter-vrf
```

## 9.7 ip routing

Use this command to enable IP routing in the global configuration mode. Use the **no** or **default** form of this command to disable this function.

**ip routing****no ip routing****default ip routing****Defaults**

This function is enabled by default.

**Command**

Global configuration mode

**Mode****Usage Guide**

IP routing is not necessary when the switch serves as bridge or VoIP gateway.

When a device functions only as a bridge or VoIP gateway, the IP routing function of the RGOS software is not required. In this case, the IP routing function of the RGOS software can be disabled. After the IP routing function is disabled, the device functions as a common host. The device can send and receive packets but cannot forward packets. All route-related configurations will be deleted except the static route configuration. A large number of static routes may be configured. If a user runs the **no ip routing** command, the configuration of a large number of static routes may be lost. To prevent this situation, the static route configuration will be hidden temporarily when the **no ip routing** command is run. If the **ip routing** command is run again, the static route configuration can be restored.

Note that if the process or whole system restarts when the **no ip routing** command is run, the static route configuration will not be reserved.

**Examples**

The following example disables IP routing.

```
Ruijie(config)# no ip routing
```

**Related****Commands** N/A**Platform****Description** This command is not supported on 2-layer devices.

## 9.8 ip static route-limit

Use this command to set the upper threshold of the static route. Use the **no** or **default** form of this command to restore the default setting.

**ip static route-limit** *number*

**no ip static route-limit**

**default ip static route-limit**

| Parameter          | Description                                                   |
|--------------------|---------------------------------------------------------------|
| <b>Description</b> | <i>number</i>                                                 |
|                    | Upper threshold of static routes in the range from 1 to 10000 |

**Defaults** The default is 1000.

**Command Mode** Global configuration mode

**Usage Guide** The goal is to control the number of static routes. You can view the upper threshold of the configured non-default static routes with the **show running-config** command.

The following example sets the upper threshold of the static routes to 9000 and then restores the setting to the default value.

### Examples

```
Ruijie(config)#ip static route-limit ?
  <1-1000000> Global limit value(default value: 1000)
Ruijie(config)# ip static route-limit 9000
Ruijie(config)# no ip static route-limit
```

**Related Commands** N/A

**Platform Description** This command is not supported on 2-layer devices.

## 9.9 ipv6 route

Use this command to configure an ipv6 static route. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 route** [ **vrf** *vrf-name* ] *ipv6-prefix / prefix-length* { *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] | *interface* [ *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] ] } [ *distance* ] [ **tag** *tag* ] [ **weight** *number* ] [ **description** *description-text* ]

**no ipv6 route** [ **vrf** *vrf-name* ] *ipv6-prefix / prefix-length* { *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] | *interface* [ *ipv6-address* [ **nexthop-vrf** { *vrf-name1* | **default** } ] ] } [ *distance* ]

**no ipv6 route [ vrf vrf\_name ] all**

**default ipv6 route [ vrf vrf-name ] ipv6-prefix / prefix-length { ipv6-address [ nexthop-vrf { vrf-name1 | default } ] | interface [ ipv6-address [ nexthop-vrf { vrf-name1 | default } ] ] } [ distance ]**

**default ipv6 route [ vrf vrf\_name ] all**

**Parameter Description**

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> vrf-name                 | Name of VRF, which must be the configured IPv6 address family multi-protocol VRF                                                                                                                                                                                                                                                                                                                                                             |
| <i>prefix-length</i>                | Mask length of the destination                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>ipv6-address</i>                 | The next hop IP address of the static route                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>interface</i>                    | (Optional) The next hop egress of the static route                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>nexthop-vrf</b> vrf-name1        | (Optional) VRF the nexthop belongs, which must be the configured IPv6 address family multi-protocol VRF.                                                                                                                                                                                                                                                                                                                                     |
| <i>distance</i>                     | (Optional) The administrative distance of the static route. The default is 1.                                                                                                                                                                                                                                                                                                                                                                |
| <i>tag</i>                          | (Optional) The tag value of the static route. The default is 0.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>weight</b> number                | (Optional) Indicates the weight of the static route, which must be specified when you configure equal-cost routes. The weight ranges from 1 to 8. When the weights of all equal-cost routes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default. |
| <b>description</b> description-text | (Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.                                                                                                                                                                                                                                                                             |

**Defaults** No IPv6 static route is configured by default.

**Command Mode** Global configuration mode

When the multi-protocol VRF deletes the IPv6 address family, the IPv6 static route of VRF that the route or nexthop belongs is deleted.

If the VRF of the IPv6 static route interface is not same as the nexthop's VRF, then this IPv6 static route takes no effect.

**Usage Guide** The default administrative distance of the static route is 1. Setting the administrative distance allows the learnt dynamic route to overwrite the static route. Setting the administrative distance of the static route can enable route backup, which is called floating route in this case. For example, the administrative distance of the OSPF is 110. You can set its administrative distance to 125. Then the data can switch over the static route when the route running OSPF fails.

The following example adds a static route to the destination network of 2001::/64 whose next hop is 2002::2 and administrative distance are 115.

```
ipv6 route 2001::/64 2002::2 115
```

**Examples**

If the static route has not a specific interface, data flows may be sent through other interface in case of interface failure. The following example configures that data flows are sent through fastethernet 0/0 to the destination network of 2001::/64.

```
ipv6 route 2001::/64 fastethernet 0/0 2002::2
```

**Related Commands**

| Command         | Description                  |
|-----------------|------------------------------|
| show ipv6 route | Displays IPv6 routing table. |

**Platform**

**Description** This command is not supported on 2-layer devices.

## 9.10 ipv6 route static bfd

Use this command to correlate the static route with BFD. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**no ipv6 route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**default ipv6 route static bfd** [ **vrf** *vrf-name* ] *interface-type interface-number gateway* [ **source** *ip-address* ]

**Parameter Description**

| Parameter                              | Description                                                                                                                                                                                                 |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i>             | (Optional) Specifies the VRF name of the static route. By default, it is global VRF,                                                                                                                        |
| <i>interface-type interface-number</i> | Interface type and interface number.                                                                                                                                                                        |
| <i>gateway</i>                         | Specifies the gateway IP address, that is, the BFD neighbor IP address. If the next hop of the static route is the neighbor, the BFD will detect whether this neighbor is reachable.                        |
| <b>source</b> <i>ipv6-address</i>      | (Optional) The source IP address of the BFD session. If the neighbor device is multi hops away, you should specify the source IP address for the BFD session. No source IP address is specified by default. |

**Defaults**

The static route is not associated with BFD by default.

**Command Mode**

Global configuration mode

**Usage Guide**

 Please make sure the BFD session parameters have been configured before executing this

command.

The following example correlates the static route with BFD, and detects the reachability of path to the neighbor `2001:1::2`.

#### Examples

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# no switchport //
Ruijie(config-if)# ip address 2001:1::1/64
Ruijie(config-if)# bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if)# exit
Ruijie(config)# ipv6 route static bfd GigabitEthernet 0/1 2001:1::2
Ruijie(config)# ipv6 route 2002::/64 GigabitEthernet 0/1 2001:1::2
```

#### Platform

**Description** This command is not supported on 2-layer devices.

## 9.11 ipv6 static route-limit

Use this command to set the upper threshold of the static route. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 static route-limit** *number*

**no ipv6 static route-limit**

**default ipv6 static route-limit**

| Parameter                           | Description                                                    |
|-------------------------------------|----------------------------------------------------------------|
| <b>Description</b><br><i>number</i> | Upper threshold of static routes in the range from 1 to 10000. |

**Defaults** The default is 1000.

**Command Mode** Global configuration mode

**Usage Guide** The goal is to control the number of static routes. You can view the upper threshold of the configured non-default static routes with the show running config command.

The following example sets the upper threshold of global ipv6 static routes to 900, default VRF static routes to 200, VRF test static routes to 100, and then restores the setting to the default value.

#### Examples

```
Ruijie(config)#ipv6 static route-limit ?
 <1-10000> Global limit value(default value: 1000)
Ruijie(config)# ipv6 static route-limit 900
```

```
Ruijie(config)# no ipv6 static route-limit
```

**Related  
Commands**

| Command         | Description                       |
|-----------------|-----------------------------------|
| ipv6 route      | Configures the IPv6 static route. |
| show ipv6 route | Displays the IPv6 routing table.  |

**Platform**

**Description** This command is not supported on 2-layer devices.

## 9.12 ipv6 unicast-routing

Use this command to enable the IPv6 route function of the RGOS. Use the **no** or **default** form of this command to disable this function.

**ipv6 unicast-routing**

**no ipv6 unicast-routing**

**default ipv6 unicast-routing**

**Parameter  
Description**

N/A

**Defaults**

This function is enabled by default.

**Command**

**Mode**

Global configuration mode

**Usage Guide**

This function can be disabled if the device is just used as the bridge-connection device or the VOIP gateway device.

**Examples**

The example disables the IPv6 route function of RGOS.

```
Ruijie# no ipv6 unicast-routing
```

**Related  
Commands**

| Command         | Description                      |
|-----------------|----------------------------------|
| ipv6 route      | Configure the IPv6 static route. |
| show ipv6 route | Displays the IPv6 routing table. |

**Platform**

**Description** This command is not supported on 2-layer devices.

## 9.13 maximum-paths

Use this command to specify the number of equivalent routes. Use the **no** or **default** form of this command is used to restore the default setting.

**maximum-paths** *number*

**no maximum-paths**

**default maximum-paths**

| Parameter   | Parameter     | Description                                           |
|-------------|---------------|-------------------------------------------------------|
| Description | <i>number</i> | Number of equivalent routes in the range from 1 to 32 |

**Defaults** The default is 32 for routers. For switches, it depends on switch models.

**Command**

**Mode** Global configuration mode

**Usage Guide** The number of equivalent routes is configured to control the number of equivalent routes. After the number of equivalent routes is configured by running the **maximum-paths** command, the number of load-sharing channels in load-sharing mode will not exceed the number of configured static routes.

You can run the **show running config** command to query the number of configured static routes. This command takes effect both to IPv4 and IPv6 addresses. After this command is configured, the maximum number of equivalent routes to an IPv4 or IPv6 destination is equal to the configured value.

**Examples** The following example sets the number of equivalent routes to 10 and then restores the default setting.

```
maximum-paths 10
no maximum-paths 10
```

## 9.14 show ip route

Use the commands to display the configuration of the IP routing table.

**show ip route** [ [ **vrf** *vrf\_name* ] [ *network* [ *mask* [ **longer-prefix** ] ] | **count** | *protocol* [ *process-id* ] | **weight** ] ]

**show ip route** [ **vrf** *vrf-name* ] [ [ **normal** | **ecmp** | **fast-reroute** ] [ *network* [ *mask* ] ]

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                      |                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------|
| <b>vrf vrf_name</b>  | (Optional) Displays the route information of the VRF.                                            |
| <i>network</i>       | (Optional) Displays the route information to the network.                                        |
| <i>mask</i>          | (Optional) Displays the route information to the network of this mask.                           |
| <b>longer-prefix</b> | (optional) Displays the routes that match the specified prefix.                                  |
| count                | (Optional) Displays the number of existent routes. (for the ECMP/WCMP route, displays one route) |
| <i>protocol</i>      | (Optional) Displays the route information of specific protocol.                                  |
| <i>process-id</i>    | (Optional) Routing protocol process ID.                                                          |
| weight               | (Optional) Displays the route information of non default weight.                                 |
| normal               | Displays normal routes and not equivalent routes or fast reroutes.                               |
| ecmp                 | Displays only equivalent routes.                                                                 |
| fast-reroute         | (Optional) Displays the master/standby route of fast reroute.                                    |

**Command** Privileged EXEC mode/ Global configuration mode/Interface configuration mode/ Routing protocol configuration mode/ Route map configuration mode

This command can display route information flexibly.

**Usage Guide** This command shows all routes. To show different attributes of routes, specify normal | ecmp | fast-reroute.

The following example displays the configuration of the IP routing table.

#### Examples

```
Ruijie# show ip route

Codes: C - Connected, L - Local, S - Static

### 9.15 show ip route static bfd

Use this command to display the IP route correlated BFD information

**show ip route [ [ vrf vrf\_name ] static bfd**

| Parameter          | Parameter    | Description                                                                            |
|--------------------|--------------|----------------------------------------------------------------------------------------|
| <b>Description</b> | vrf vrf-name | (Optional) Displays route information of the specified VRF. The default is global VRF. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to display the IP route correlated BFD information

The following example displays the IP route correlated BFD information,

```
Ruijie(config)#show ip route static bfd
S    10.0.0.0/8 via 100.100.100.25, GigabitEthernet 0/3, BFD state is Up
S    20.0.0.0/8 via 200.100.100.25, GigabitEthernet 0/4, BFD state is Admin
```

**Examples**

| Field     | Description                               |
|-----------|-------------------------------------------|
| S         | Static route                              |
| BFD state | State of the static route correlated BFD. |

**Related Commands** N/A

**Platform**

**Description** This command is not supported on 2-layer devices.

## 9.16 show ip route summary

Use this command to display the statistical information about one routing table.

**show ip route [vrf *vrf\_name*] summary**

Use this command to display the statistical information about all routing tables.

**show ip route summary all**

|                    | Parameter       | Description |
|--------------------|-----------------|-------------|
| <b>Parameter</b>   |                 |             |
| <b>Description</b> | <i>vrf-name</i> | VRF name    |

**Defaults** N/A

**Command**

**Mode** Privileged EXEC mode

**Usage**

**guideline** N/A

The following example displays the statistics of the global routing table.

```
Ruijie# show ip route summary
Codes: NORMAL - Normal route ECMP - ECMP route FRR - Fast-Reroute route

Memory: 2000 bytes
Entries: 22,based on route prefixes
          NORMAL ECMP FRR TOTAL
Connected 3 0 0 3
Static 2 1 1 4
RIP 1 2 1 4
OSPF 2 1 1 4
ISIS 1 2 0 3
BGP 2 1 1 4
TOTAL 11 7 4 22
```

The following example displays the statistics of all routing tables.

```
Ruijie# show ip route summary all
Codes: NORMAL - Normal route ECMP - ECMP route FRR - Fast-Reroute route

IP routing table count:2
Total
Memory: 4000 bytes
Entries: 44,based on route prefixes
          NORMAL ECMP FRR TOTAL
Connected 6 0 0 6
Static 4 2 2 8
RIP 2 4 2 8
OSPF 4 2 2 8
ISIS 2 4 0 6
BGP 4 2 2 8
TOTAL 22 14 8 44

Global
Memory: 2000 bytes
Entries: 22,based on route prefixes
          NORMAL ECMP FRR TOTAL
Connected 3 0 0 3
Static 2 1 1 4
RIP 1 2 1 4
OSPF 2 1 1 4
ISIS 1 2 0 3
BGP 2 1 1 4
TOTAL 11 7 4 22
```

## Examples

```

VRF1
Memory: 2000 bytes
  Entries: 22, based on route prefixes
  Entries: 29, based on route nexthops
NORMAL
ECMP FRR TOTAL
  Connected 3 0 0 3
  Static 2 1 1 4
  RIP 1 2 1 4
  OSPF 2 1 1 4
  ISIS 1 2 0 3
  BGP 2 1 1 4
  TOTAL 11 7 4 22
    
```

| Field     | Description                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| NORMAL    | Type of the table entries. Value:<br>NORMAL: common routes (not ECMP or FRR);<br>ECMP: equivalent route;<br>FRR: fast reroute;<br>TOTAL: total    |
| Memory    | Memory occupied by the table.                                                                                                                     |
| Entries   | Number of entries (based on prefix, not next-hop)                                                                                                 |
| Connected | Protocol type. Value:<br>Connected: direct connection;<br>Static: static;<br>RIP: RIP;<br>OSPF: OSPF;<br>ISIS: ISIS;<br>BGP: BGP;<br>TOTAL: total |

### 9.17 show ip route track-table

Use this command to display the IP route correlated Track information.

**show ip route [ [ vrf vrf\_name ] track-table**

| Parameter                          | Description                                                                                     |
|------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>Description</b><br>vrf vrf_name | (Optional) Displays the route information of the specified VRF name. The default is global VRF, |
| <b>Defaults</b>                    | N/A                                                                                             |

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to display the IP route correlated Track information.

The following example displays the IP route correlated Track information.

```
Ruijie(config)#show ip route track-table
ip route 10.0.0.0 255.0.0.0 GigabitEthernet 0/0 track 2 state is [up]
ip route 20.0.0.0 255.0.0.0 GigabitEthernet 0/0 2 track 3 state is [down]
```

**Examples**

:

| Field | Description        |
|-------|--------------------|
| track | Track target index |
| state | Track target state |

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform**

**Description** This command is not supported on 2-layer devices.

## 9.18 show ipv6 route

Use the command to display the configuration of the IPv6 routing table.

```
show ipv6 route [ [ vrf vrf_name ] [ ipv6-prefix / prefix-length [ longer-prefixes ] | protocol [ process-id ] | weight ] ]
```

| Parameter                        | Description                                                               |
|----------------------------------|---------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i>       | (Optional) Specifies a VRF.                                               |
| <i>ipv6-prefix/prefix-length</i> | (Optional) Specifies a prefix for route's IPv6 address.                   |
| <b>longer-prefixes</b>           | (Optional) Displays the route with an IPv6 address prefix mostly matched. |
| <i>protocol</i>                  | ((Optional) Displays the route information of specific protocol.          |
| <i>process-id</i>                | (Optional) Specifies a route process ID.                                  |
| <b>weight</b>                    | (Optional) Displays the non-default-weight routes only.                   |

**Defaults** All routes are displayed by default.

**Command**

**Mode** Privileged EXEC mode

**Usage Guide** Use this command to display route information.

The following example displays the IPv6 routing table.

```
Ruijie(config)# show ipv6 route

IPv6 routing table - Default - 7 entries
Codes: C - Connected, L - Local, S - Static
       R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       IA - Inter area

C    10::/64 via Loopback 1, directly connected
L    10::1/128 via Loopback 1, local host
S    20::/64 [20/0] via 10::4, Loopback 1C
C    FE80::/10 via Null 0, directly connected
C    FE80::/64 via Loopback 1, directly connected
L    FE80::2D0:F8FF:FE22:33AB/128 via Loopback 1, local host
```

**Examples**

| Field   | Description                                                                                                                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| O       | Source routing protocol, which may be:<br>C: directly connected route<br>S: static route<br>R: RIP route<br>B: BGP route<br>O: OSPF route<br>I: IS-IS route                                                                                                                                                       |
| E2      | Route type, which may be:<br>E1: OSPF external route type 1<br>E2: OSPF external route type 2<br>N1: OSPF NSSA external type 1<br>N2: OSPF NSSA external type 2<br>IA: OSPF area internal route<br>SU: IS-IS summary route<br>L1: IS-IS level-1 route<br>L2: IS-IS level-2 route<br>IA: IS-IS area internal route |
| 20::/64 | Network address and mask of the destination network                                                                                                                                                                                                                                                               |
| [20/0]  | Administrative distance/metric                                                                                                                                                                                                                                                                                    |

| Related Commands | Command                 | Description                       |
|------------------|-------------------------|-----------------------------------|
|                  | <code>ipv6 route</code> | Configures the IPv6 static route. |

**Platform**

**Description** This command is not supported on 2-layer devices.

## 9.19 show ip route static bfd

Use this command to display the IPv6 route correlated BFD information

**show ipv6 route [ [ vrf vrf\_name ] static bfd**

| Parameter          | Parameter                 | Description                                                                                                          |
|--------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <code>vrf vrf-name</code> | (Optional) Displays the route information of the designated VRF name of the static route. The default is global VRF, |

**Defaults** N/A

**Command Mode**

Privileged EXEC mode

**Usage Guide**

Use this command to display the IPv6 route correlated BFD information.

The following example displays the IPv6 route correlated BFD information.

```
Ruijie(config)#show ip route static bfd
S    25::/64 via 100::25, GigabitEthernet 0/3, BFD state is Up
S    26::/64 via 200::25, GigabitEthernet 0/4, BFD state is Admin
```

**Examples**

| Field     | Description                              |
|-----------|------------------------------------------|
| S         | Static route                             |
| BFD state | State of the static route associated BFD |

**Related**

**Commands** N/A

**Platform**

**Description** This command is not supported on 2-layer devices.

## 9.20 show ipv6 route summary

Use this command to display the statistics of the IPv6 routing table of a specified VRF.

**show ipv6 route [ vrf vrf-name ] summary**

Use this command to display statistics of all IPv6 routing tables.

**show ipv6 route summary all**

| Parameter                              | Description                                                                                                                                |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameter</b><br><b>Description</b> | <i>vrf-name</i><br>(Optional) VRF name. If no VRF name is specified, statistics of the IPv6 routing table of the global VRF are displayed. |
| <b>Defaults</b>                        | N/A                                                                                                                                        |
| <b>Command</b>                         |                                                                                                                                            |
| <b>Mode</b>                            | Privileged EXEC mode                                                                                                                       |
| <b>Usage Guide</b>                     | N/A                                                                                                                                        |

The following example displays statistics of IPv6 routing table of the global VRF.

```
Ruijie#show ipv6 route summary
IPv6 routing table name is - Default(0) global scope - 5 entries
IPv6 routing table default maximum-paths is 32
Local          2
Connected     3
Static         0
PIP            0
OSPF           0
BGP            0
-----
Total          5
```

The following example displays t statistics of all IPv6 routing tables.

**Examples**

```
Ruijie#show ipv6 route summary
IPv6 routing table name is - Default(0) global scope - 5 entries
IPv6 routing table default maximum-paths is 32
Local          2
Connected     3
Static         0
PIP            0
OSPF           0
BGP            0
-----
Total          5
```

| Field     | Description                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------|

**Description** This command is not supported on 2-layer devices.

## 10 Protocol-independent Commands

### 10.1 accept-lifetime

Use this command in the encryption key configuration mode to specify the lifetime of an encryption key in its receiving direction. Use the no form of this command to restore the default value.

**accept-lifetime** *start-time* {infinite | *end-time* | **duration seconds**}

**no accept-lifetime**

| Parameter description | Parameter               | Description                                                                                 |
|-----------------------|-------------------------|---------------------------------------------------------------------------------------------|
|                       | <i>start-time</i>       | Start time of the lifetime.                                                                 |
|                       | <b>infinite</b>         | Indicates that the encryption key is valid for ever.                                        |
|                       | <i>end-time</i>         | <i>End time of the encryption key. It must be later than the start time.</i>                |
|                       | <b>duration seconds</b> | Duration of the encryption key after the start time. The value ranges from 1 to 2147483646. |

**Default** infinite

**Command mode** Encryption key configuration mode

**Usage guideline** Use this command to specify the lifetime of an encryption key in its receiving direction.

**Examples** The following example configures the lifetime from 0:00 on September 9, 2000 to 0:00 on October 12, 2011.

```
Ruijie(config)# key chain ripkeys
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)#accept-lifetime 00:00:00 Sep 9 2000 00:00:00 Dec
12 2011
```

**Platform description** -

### 10.2 ip as-path access-list

Use this command to configure an autonomous system (AS) path filter using a regular expression. Use

the **no** form of this command to remove the AS path filter using a regular expression.

**ip as-path access-list** *path-list-num* { **permit** | **deny** } *regular-expression*

**no ip as-path access-list** *path-list-num* [ { **permit** | **deny** } *regular-expression* ]

| Parameter   | Parameter                 | Description                                                                                                  |
|-------------|---------------------------|--------------------------------------------------------------------------------------------------------------|
| description | <i>path-list-num</i>      | Specifies the AS-path access-list number. The range is from 1 to 500.                                        |
|             | <b>permit</b>             | Permits advertisement based on matching conditions.                                                          |
|             | <b>deny</b>               | Denies advertisement based on matching conditions.                                                           |
|             | <i>regular-expression</i> | Regular expression that defines the AS-path filter. The expression length range is from 1 to 255 characters. |

**Default** By default, no AS path filter using a regular expression is configured.

**Command mode** Global configuration mode

**Usage guideline** N/A

**Examples** The following example configures an AS path filter matching the path which contains AS number 123 only.

```
Ruijie(config)# ip as-path access-list 105 deny ^123$
```

## 10.3 ip community-list

Use this command to define a standard or expanded community list and control access to it. Use the **no** form of this command to remove the setting.

**ip community-list** { *community-list-number* | **standard** *community-list-name* } { **permit** | **deny** }

**ip community-list** { *community-list-number* | **expanded** *community-list-name* } { **permit** | **deny** }  
[ *regular-expression* ]

| Parameter   | Parameter | Description                                               |
|-------------|-----------|-----------------------------------------------------------|
| description | standard  | Indicates standard community list numbered in 1 to 99.    |
|             | expanded  | Indicates expanded community list numbered in 100 to 199. |
|             | permit    | Permits access to the community list.                     |

|                         |                                                                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| deny                    | Denies access to the community list.                                                                                                              |
| <i>community-number</i> | Community number in the form of AA:NN(AS number/2-byte numerical) in the range of 1 to 255 characters. It may also be one of the following value: |

**Default configuration**

None

**Command mode**

Global configuration mode.

**Usage**

**guidelines**

This command is used to define the community list for BGP.

**Examples**

```
Ruijie(config)# ip community-list standard 1 deny 100.20.200.20
Ruijie(config)# ip community-list standard 1 permit internet
```

**Related commands**

| Command                   | Description                                                                 |
|---------------------------|-----------------------------------------------------------------------------|
| match community           | Match the community list.                                                   |
| set community-list delete | Remove the community value of the BGP path according to the community list. |
| show ip community-list    | Show the community list information.                                        |

## 10.4 ip extcommunity-list

Use this command to create an extcommunity list and add an entry to the list. Use the **no** form of this command to remove the setting.

**ip extcommunity-list** {*expanded-list* | **expanded** *list-name*} {**permit** | **deny**} [*regular-expression*]

**ip extcommunity-list** {*standard-list* | **standard** *list-name*} {**permit** | **deny**} [*rt value*] [*soo value*]

**no ip extcommunity-list** {*expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name*}

**ip extcommunity-list** {*expanded-list* | **expanded** *list-name*| *standard-list* | **standard** *list-name*}

**no ip extcommunity-list** {*expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name*}

**Parameter description**

| Parameter                        | Description                                                                                                                                                            |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>expand-list</i>               | Indicates an extended extcommunity list, ranging from 100 to 199. One extcommunity list may contain multiple rules.                                                    |
| <i>standard-list</i>             | Indicates a standard extcommunity list, ranging from 1 to 99. One extcommunity list may contain multiple rules.                                                        |
| <b>expanded</b> <i>list-name</i> | Indicates the name of an extended extcommunity, comprising not more than 32 characters. When using this parameter, you enter the extcommunity list configuration mode. |

|                                  |                                                                                                                                                                                                                                     |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>standard</b> <i>list-name</i> | Indicates the name of a standard extcommunity list, comprising not more than 32 characters. When using this parameter, you enter the extcommunity list configuration mode.                                                          |
| <b>permit</b>                    | Defines an extcommunity rule for permitting.                                                                                                                                                                                        |
| <b>deny</b>                      | Defines an extcommunity rule for denying.                                                                                                                                                                                           |
| <i>regular-expression</i>        | (optional) Defines a matching template that is used to match an extcommunity.                                                                                                                                                       |
| <i>sequence-number</i>           | (Optional) Defines the sequence number of a rule, ranging from 1 to 2,147,483,647. If no sequence number is specified, the sequence number automatically increases by 10 when a rule is added by default. The initial number is 10. |
| <b>rt</b>                        | (Optional) Sets the RT attribute value. This command can be used only for the standard extcommunity configuration, but not for the extended extcommunity configuration.                                                             |
| <b>soo</b>                       | (Optional) Sets the SOO attribute value. This command can be used only for the standard extcommunity configuration, but not for the extended extcommunity configuration.                                                            |
| <i>value</i>                     | Indicates the value of an extended community (extend_community_value).                                                                                                                                                              |

**Default** It is disabled by default.

**Command mode** Global configuration mode and ip extcommunity-list configuration mode.

**Usage guidelines** This command is used to define the extcommunity list.

1. The following example defines an ip extcommunity-list.

```
Ruijie(config)# ip extcommunity-list 1 permit rt 100: 1
Ruijie(config)# ip extcommunity-list standard aaa permit rt
100: 2
Ruijie(config)# ip extcommunity-list expanded ext1 permit 200: [0~9][0~9]
```

**Examples** 2. The following example displays how to use ip extcommunity.

```
Ruijie(config)# route-map rt_in_filter
Ruijie(config-route-map)# match extcommunity 1
Ruijie(config-route-map)# match extcommunity ext1
Ruijie(config)# router bgp 100
Ruijie(config-router)# address-family vpn
Ruijie(config-router-af)#neighbor 3.3.3.3 send-community extended
Ruijie(config-router-af)#neighbor 3.3.3.3 route-map rt_in_filter in
```

## 10.5 ip prefix-list

Use this command to create a prefix list or add an entry to the prefix list. Use the **no** form of this command to remove the prefix list or an entry.

**ip prefix-list** *prefix-list-name* [ **seq** *seq-number*] { **deny** | **permit** } *ip-prefix* [**ge** *minimum-prefix-length*][**le** *maximum-prefix-length*]

**no ip prefix-list** *prefix-list-name* [ **seq** *seq-number*] { **deny** | **permit** } *ip-prefix* [**ge** *minimum-prefix-length*][**le** *maximum-prefix-length*]

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>prefix-list-name</i>      | Name of the prefix list                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>seq-number</i>            | Sequence number of an entry in the range of 1 to 2147483647. When you execute this command to add an entry without a sequence number, the system allocates a default sequence number for the entry. The default sequence number of the first entry is 5. Every subsequential entry without a sequence number uses the time of 5 larger than the previous sequence number as the default sequence number. |
| deny                         | Deny the route matching the prefix list.                                                                                                                                                                                                                                                                                                                                                                 |
| permit                       | Permit the route matching the prefix list.                                                                                                                                                                                                                                                                                                                                                               |
| <i>ip-prefix</i>             | Network address and mask. Network address can be any valid IP address and the mask length is in the range of 0 to 32.                                                                                                                                                                                                                                                                                    |
| <i>minimum-prefix-length</i> | (Optional) Minimum length of the prefix (the starting length)<br>Note: "ge" indicates the operation of "larger than" and "equivalent to".                                                                                                                                                                                                                                                                |
| <i>maximum-prefix-length</i> | (Optional) Maximum length of the prefix (the ending length)<br>Note: "le" indicates the operation of "less than" and "equivalent to".                                                                                                                                                                                                                                                                    |

### Parameter description

### Default configuration

None

### Command mode

Global configuration mode.

### Usage guidelines

The ip prefix-list command configures the prefix list, with the permit or deny keyword to determine the action in case of matching.

You can execute this command to define an exact match, or use "ge" or "le" to define a range match for a prefix for flexible configuration. "ge" indicates the range of minimum-prefix-length to 32; "le" indicates the range of the mask length of the IP prefix to maximum-prefix-length; "ge" and "le" indicates the range of minimum-prefix-length to maximum-prefix-length, namely, mask length of IP prefix <

minimum-prefix-length < maximum-prefix-length <=32.

The following example filters the RIP routes the OSPF redistributes by the destination IP address following the rule defined in the associated IP prefix list, for example, redistribute the routes whose destination IP address is in the range 201.1.1.0/24.

#### Examples

```
Ruijie# configure terminal
Ruijie(config)# ip prefix-list pre1 permit 201.1.1.0/24
Ruijie(config)# router ospf
Ruijie(config-router)# distribute-list prefix pre1 out rip
Ruijie(config-router)# end
```

## 10.6 ip prefix-list description

Use this command to add the description of a prefix list. Use the **no** form of this command to delete the description.

**ip prefix-list** *prefix-list-name* **description** *description-text*

**no ip prefix-list** *prefix-list-name* **description**

| Parameter               | Description                    |
|-------------------------|--------------------------------|
| <i>prefix-list-name</i> | Name of the prefix list        |
| <i>description-text</i> | Description of the prefix list |

#### Default

**configuration** No description is added for a prefix list, by default.

#### Command

**mode** Global configuration mode

The example below adds the description for the prefix list:

#### Examples

```
Ruijie# configure terminal
Ruijie(config)# ip prefix-list pre description Deny routes from Net-A
```

## 10.7 ip prefix-list sequence-number

Use this command to enable sort function for a prefix list. Use the **no** form of this command to disable the sort function.

**ip prefix-list** **sequence-number**

**no ip prefix-list** **sequence-number**

#### Parameter

**description** Disabled

**Default**

**configuration** No sequence number is added for a prefix list, by default.

**Command**

**mode** Global configuration mode

The example below adds a sequence number for the prefix list:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip prefix-list pre description deny routes from Net-A
```

**Related commands**

| Command        | Description                |
|----------------|----------------------------|
| ip prefix-list | Configure the prefix list. |

**Platform**

**description** N/A

## 10.8 ipv6 prefix-list

Use this command to create an IPv6 prefix list or add an entry in the prefix list. Use the **no** form of this command to delete an IPv6 prefix list or an entry in the prefix list.

**ipv6 prefix-list** *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv6-prefix* [**ge** *minimum-prefix-length*][**le** *maximum-prefix-length*]

**no ipv6 prefix-list** *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv6-prefix* [**ge** *minimum-prefix-length*][**le** *maximum-prefix-length*]

**Parameter description**

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>prefix-list-name</i>      | Name of the prefix list                                                                                                                                                                                                                                                                                                                                      |
| <i>seq-number</i>            | Sequence number of an entry in the prefix list. Its range is 1 to 4294967294. If the sequence number is not specified in this command, the system will allocate a default one for the entry. The default sequence number of the first entry is 5, and that of each subsequent one is the product of adding 5 to the sequence number of the proceeding entry. |
| permit                       | Permit the access to the matching result.                                                                                                                                                                                                                                                                                                                    |
| deny                         | Deny the access to the matching result.                                                                                                                                                                                                                                                                                                                      |
| <i>ipv6-prefix</i>           | Network address and its mask. The network address can be any valid IP address. The mask can be 0 to 32 characters.                                                                                                                                                                                                                                           |
| <i>minimum-prefix-length</i> | (Optional) Minimum length of the prefix (the starting length)<br>Note: "ge" indicates the operation of "larger than" and "equivalent to".                                                                                                                                                                                                                    |
| <i>maximum-prefix-length</i> | (Optional) Maximum length of the prefix (the ending length)<br>Note: "le" indicates the operation of "less than" and "equivalent to".                                                                                                                                                                                                                        |

**Default**

No prefix list is created.

**configuration****Command**

**mode** Global configuration mode

The ipv6 prefix-list command configures the prefix list, with the permit or deny keyword to determine the action in case of matching.

**Usage guideline**

You can execute this command to define an exact match, or use “ge” or “le” to define a range match for a prefix for flexible configuration. “ge” indicates the range of minimum-prefix-length to 128; “le” indicates the range of the mask length of the IP prefix to maximum-prefix-length; “ge” and “le” indicates the range of minimum-prefix-length to maximum-prefix-length, namely, ipv6-prefix mask length < minimum-prefix-length < maximum-prefix-length <= 128

The following example filters the RIP routes the OSPF redistributes by the destination IP address following the rule defined in the associated IP prefix list, for example, redistribute the routes whose destination IP address is in the range 2222::/64.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 prefix-list pre1 permit 2222::64
Ruijie(config)# ipv6 router ospf
Ruijie(config-router)# distribute-list prefix pre out rip
Ruijie(config-router)# end
```

## 10.9 ipv6 prefix-list description

Use this command to add the description of an IPv6 prefix list. Use the **no** form of this command to delete the description.

**ipv6 prefix-list** *prefix-lis-name* **description** *description-text*

**no ipv6 prefix-list** *prefix-lis-name* **description**

| Parameter          | Parameter               | Description                         |
|--------------------|-------------------------|-------------------------------------|
| <b>description</b> | <i>prefix-lis-name</i>  | Name of the ipv6 prefix list        |
|                    | <i>description-text</i> | Description of the ipv6 prefix list |

**Default**

**configuration** No description is added for an IPv6 prefix list, by default.

**Command**

**mode** Global configuration mode

The example below adds the description for the prefix list:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 prefix-list pre description Deny routes from Net-A
```

| Related commands | Command          | Description                     |
|------------------|------------------|---------------------------------|
|                  | ipv6 prefix-list | Configure the IPv6 prefix list. |

## 10.10 ipv6 prefix-list sequence-number

Use this command to enable the sorting function for an IPv6 prefix list. Use the **no** form of this command to remove the settings.

**ipv6 prefix-list sequence-number**

**no ipv6 prefix-list sequence-number**

### Parameter description

### Default

**configuration** No sequence number is added for a prefix list, by default.

### Command

**mode** Global configuration mode

The example below adds a sequence number for the prefix list:

### Examples

```
Ruijie# configure terminal
Ruijie(config)# ipv6 prefix-list pre description Deny routes from Net-A
```

| Related commands | Command          | Description                     |
|------------------|------------------|---------------------------------|
|                  | ipv6 prefix-list | Configure the IPv6 prefix list. |

## 10.11 key

Use this command to define an encryption key and enter the encryption key chain configuration mode.

Use the **no** form of this command to delete it.

**key key-id**

**no key key-id**

| Parameter description | Parameter | Description                           |
|-----------------------|-----------|---------------------------------------|
|                       | key-id    | Key ID, ranging from 0 to 2147483647. |

### Default

No encryption key is configured.

### Command mode

Encryption key chain configuration mode.

**Usage guideline** Use this command to define an encryption key.

**Examples** The following example configures encryption key chain ripkeys and key 1.

```
Ruijie(config)# key chain ripkeys
Ruijie(config-keychain)# key 1
```

| Related command | Command | Description |
|-----------------|---------|-------------|
|                 | -       | -           |

**Platform description** -

## 10.12 key chain

Use this command to define a key chain and enter the key chain configuration mode. Use the no form of this command to delete it.

**key chain** *key-chain-name*

**no key chain** *key-chain-name*

| Parameter description | Parameter             | Description     |
|-----------------------|-----------------------|-----------------|
|                       | <i>key-chain-name</i> | Key chain name. |

**Default** No key chain is configured.

**Command mode** Global configuration mode.

**Usage guideline**  For a key chain to take effect, you need to configure at least one key.

**Examples** The following example configures key chain ripkeys and enters the key chain configuration mode.

```
Ruijie(config)# key chain ripkeys
```

| Related command | Command | Description |
|-----------------|---------|-------------|
|                 | -       | -           |

**Platform description** -

## 10.13 key-string

Use this command to specify a key string. Use the **no** form of this command to delete it.

**key-string** [0|7] *text*

**no key-string**

| Parameter   | Parameter   | Description            |
|-------------|-------------|------------------------|
| description | 0           | Use plaintext.         |
|             | 7           | Use encryption.        |
|             | <i>text</i> | Authentication string. |

**Default** No key string is configured.

**Command mode** Encryption key configuration mode.

**Usage guideline** Use this command to specify a key string.

**Examples** The following example configures key chain ripkeys, key 1 and the key string abc:

```
Ruijie(config)# key chain ripkeys
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)#key-string abc
```

| Related command | Command | Description |
|-----------------|---------|-------------|
|                 | -       | -           |

**Platform description** -

## 10.14 match as-path

Use this command to redistribute the routes of AS\_PATH attribute permitted by the access list in the route map configuration mode. Use the **no** form of this command to remove the setting.

**match as-path** *as-path-acl-list-num* [ *as-path-acl-list-number.....*]

**no match as-path** [ *as-path-acl-list-num.....*]

| Parameter   | Parameter                   | Description                           |
|-------------|-----------------------------|---------------------------------------|
| description | <i>as-path-acl-list-num</i> | ACL number, in the range of 1 to 500. |
|             |                             |                                       |

**Default** None.

**configuration****Command**

**mode** Route map configuration mode.

The match as-path can be followed by an access list number or name.

**Usage**

One or more match or set commands can be executed to configure one route map. If the match

**guidelines**

command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

**Examples**

```
Ruijie(config)# route-map ROUTEMAP2IBGP
Ruijie(config-route-map)# match as-path 20 30
```

**Related commands**

| Command                    | Description                                       |
|----------------------------|---------------------------------------------------|
| <b>match community</b>     | Match the community.                              |
| <b>match metric</b>        | Match the metric.                                 |
| <b>match origin</b>        | Match the source of routes.                       |
| <b>set as-path prepend</b> | Set the AS_PATH attribute of redistributed routes |
| <b>set metric</b>          | Set the metric.                                   |
| <b>set metric-type</b>     | Set the metric type.                              |

## 10.15 match community

Use this command to redistribute the routes matching the Community attribute permitted by the ACL in the route map configuration mode. Use the **no** form of this command to remove the setting.

**match community** { *community-list-number* | *community-list-name* } [**exact-match**]

[ { *community-list-number* | *community-list-name* } [**exact-match**] ...]

**no match community** { *community-list-number* | *community-list-name* } [**exact-match**]

[ { *community-list-number* | *community-list-name* } [**exact-match**] ...]

**Parameter description**

| Parameter                           | Description                                                                                                                     |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b><i>community-list-number</i></b> | Number of the standard community list in the range 1 to 99.<br>Number of the extended community list in the range of 100 to 199 |
| <b><i>communitys-list-name</i></b>  | Name of the community list in the range of less than 80 characters                                                              |
| <b>exact-match</b>                  | Match the community list exactly.                                                                                               |

**Default**

**configuration** None.

**Command**

**mode** Route map configuration mode.

**Usage**

The match community can be followed by more than one community list number or name, but the

**guidelines**

- total of community lists and names should not be greater than 6.
- Each exact-match applies to only the previous list, not all the lists.
- One or more match or set commands can be executed to configure one route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

**Examples**

```
Ruijie(config)# ip community-list 1 permit 100:2 100:30
Ruijie(config)# route-map set_lopref
Ruijie(config-route-map)# match community 1 exact-match
Ruijie(config-route-map)# set local-preference 20
```

**Related commands**

| Command                    | Description                  |
|----------------------------|------------------------------|
| <b>match as-path</b>       | Match the AS_PATH attribute. |
| <b>match metric</b>        | Match the metric.            |
| <b>match origin</b>        | Match the source.            |
| <b>set as-path prepend</b> | Set the AS_PATH attribute.   |
| <b>set metric</b>          | Set the metric.              |
| <b>set metric-type</b>     | Set the metric type.         |

## 10.16 match extcommunity

Use this command to define the match rule for the BGP extcommunity. Use the no form of this command to cancel the setting.

**match extcommunity** { *standard-list-number* | *standard-list-name* | *expanded-list-num* | *expanded-list-name* }

**no match extcommunity** { *standard-list-number* | *standard-list-name* | *expanded-list-num* | *expanded-list-name* }

**Parameter description**

| Parameter                          | Description                                                                                                                   |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b><i>standard-list-number</i></b> | Standard extcommunity list number, ranging from 1 to 99.<br>An extcommunity list may contains multiple excommunity values.    |
| <b><i>standard-list-name</i></b>   | Standard excommunity name.<br>An extcommunity list may contains multiple excommunity values.                                  |
| <b><i>expanded-list-num</i></b>    | Expanded extcommunity list number, ranging from 100 to 199.<br>An extcommunity list may contains multiple excommunity values. |
| <b><i>expanded-list-name</i></b>   | Expanded excommunity name.<br>An extcommunity list may contains multiple excommunity values.                                  |

**Default** The rule is not defined in the associated route map.

**Command mode** Route map configuration mode.

**Usage** There are the following scenarios for a route map with an extcommunity:

**guideline**

1. The route map associated with **import map** uses the RT attribute to filter imported VRF routes.
2. The route maps associated with **neighbor route-map in** and **neighbor route-map out** are configured in the BGP VPNv4 address family mode and use the RT attribute to filter VPNv4 routes sent to or by BGP peers.

**Examples** 1. Define two extcommunity:

```
Ruijie(config)# ip extcommunity-list 1 permit rt 100: 1
Ruijie(config)# ip extcommunity-list 1 permit rt 100: 2
```

2. Define match rules in the route map:

```
Ruijie(config)# route-map rt
Ruijie(config-route-map)# match extcommunity 1
```

3. Use the route map.

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# address-family vpnv4
Ruijie(config-router-af)# neighbor 3.3.3.3 route-map rt in
```

| Related command | Command                          | Description                  |
|-----------------|----------------------------------|------------------------------|
|                 | <b>ip extcommunity-list</b>      | Create an extcommunity list. |
|                 | <b>show ip extcommunity-list</b> | Show an extcommunity list.   |

**Platform** -

**description**

## 10.17 match interface

Use **match interface** command to redistribute the routes whose next hop is the specified interface.

Use the **no** form of this command to remove the setting.

**match interface** *interface-type interface-number* [...*interface-type interface-number*]

**no match interface** [*interface-type interface-number* [...*interface-type interface-number*]]

| Parameter description | Parameter               | Description      |
|-----------------------|-------------------------|------------------|
|                       | <i>interface-type</i>   | Interface type   |
|                       | <i>interface-number</i> | Interface number |

**Default configuration** None.

**Command mode** Route map configuration mode.

**Usage** This command can be followed by multiple interfaces.

**guidelines** You can redistribute the routes from one routing process to another routing process. For example,

you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The route map can be configured very flexibly for route redistribution and policy-based routing. No matter how the route map is used, the configuration principle is the same, except that different command sets are used. Even if it is used on the route redistribution, different routing protocols can use different commands with the route map.

The following example redistributes the RIP route with the next hop of fastethernet 0/0 in the OSPF routing protocol.

### Examples

```
router ospf
redistribute rip subnets route-map redrip
network 192.168.12.0 0.0.0.255 area 0

route-map redrip permit 10
match interface fastethernet 0/0
```

| Command                      | Description                                       |
|------------------------------|---------------------------------------------------|
| <b>match ip address</b>      | Match the address in the access list.             |
| <b>match ip next-hop</b>     | Match the next-hop IP address in the access list. |
| <b>match ip route-source</b> | Match the source IP address in the access list.   |
| <b>match metric</b>          | Match the metric.                                 |
| <b>match route-type</b>      | Match the route type.                             |
| <b>match tag</b>             | Match the tag.                                    |
| <b>set metric</b>            | Set the metric.                                   |
| <b>set metric-type</b>       | Set the metric type.                              |
| <b>set tag</b>               | Set the tag.                                      |

## 10.18 match ip address

Use **match ip address** command to redistribute the routes matching the IP address permitted by the ACL or the prefix list. Use the **no** form of this command to remove the setting.

**match ip address** {*access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*]}

**no match ip address** [*access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*]]

|                              | Parameter                           | Description                       |
|------------------------------|-------------------------------------|-----------------------------------|
| <b>Parameter description</b> | <i>access-list-number</i>           | Number of the access list         |
|                              | <i>access-list-name</i>             | Name of the access list           |
|                              | prefix-list <i>prefix-list-name</i> | Specify the prefix list to match. |

**Default configuration** None.

**Command mode** Route map configuration mode.

Multiple access list numbers or names may follow match ip address.

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

**Usage guidelines** For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The route map can be configured very flexibly for route redistribution and policy-based routing. No matter how the route map is used, the configuration principle is the same, except that different command sets are used. Even if it is used on the route redistribution, different routing protocols can use different commands with the route map.

The following example enables the OSPF routing protocol to redistribute RIP routes that match access list 10, with the route type being type-1 external type and the default metric being 40.

#### Examples

```
router ospf
redistribute rip subnets route-map redrip
network 192.168.12.0 0.0.0.255 area 0

access-list 10 permit 200.168.23.0 0.0.0.255

route-map redrip permit 10
match ip address 10
set metric 40
set metric-type type-1!
```

|                         | Command                      | Description                                        |
|-------------------------|------------------------------|----------------------------------------------------|
| <b>Related commands</b> | <b>access-list</b>           | Set the access list.                               |
|                         | <b>match interface</b>       | Match the next-hop interface of the route.         |
|                         | <b>match ip next-hop</b>     | Match the next-hop address in the access list.     |
|                         | <b>match ip route-source</b> | Match the route source address in the access list. |

|                         |                       |
|-------------------------|-----------------------|
| <b>match metric</b>     | Match the metric.     |
| <b>match route-type</b> | Match the route type. |
| <b>match tag</b>        | Match the tag.        |
| <b>set metric</b>       | Set the metric.       |
| <b>set metric-type</b>  | Set the metric type.  |
| <b>set tag</b>          | Set the tag.          |

## 10.19 match ip next-hop

Use **match ip next-hop** command to redistribute the routes whose next-hop IP address matches the access list or the prefix list. Use the **no** form of this command to remove the setting.

**match ip next-hop** {*access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*]}

**no match ip next-hop** [*access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*]]

|                    | Parameter                                  | Description                       |
|--------------------|--------------------------------------------|-----------------------------------|
| <b>Parameter</b>   | <i>access-list-number</i>                  | Number of the access list         |
| <b>description</b> | <i>access-list-name</i>                    | Name of the access list           |
|                    | <i>prefix-list</i> <i>prefix-list-name</i> | Specify the prefix list to match. |

### Default

**configuration** None.

### Command

**mode** Route map configuration mode.

Multiple access list numbers or names may follow match ip next-hop.

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

### Usage

**guidelines** For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

In the example below, the OSPF routing protocol redistributes the RIP routes. As long as the next hop address of the RIP route matches the access list 10 or 20, the OSPF allows for redistribution.

### Examples

```
router ospf
 redistribute rip subnets route-map redrip
```

```
network 192.168.12.0 0.0.0.255 area 0

access-list 10 permit 192.168.100.1
access-list 20 permit 172.16.10.1

route-map redrip permit 10
match ip next-hop 10 20
```

**Related commands**

| Command                      | Description                                        |
|------------------------------|----------------------------------------------------|
| <b>access-list</b>           | Set the access list.                               |
| <b>match ip address</b>      | Match the IP address in the access list.           |
| <b>match interface</b>       | Match the next-hop interface of the route.         |
| <b>match ip route-source</b> | Match the route source address in the access list. |
| <b>match metric</b>          | Match the metric.                                  |
| <b>match route-type</b>      | Match the route type.                              |
| <b>match tag</b>             | Match the tag.                                     |
| <b>set metric</b>            | Set the metric.                                    |
| <b>set metric-type</b>       | Set the metric type.                               |
| <b>set tag</b>               | Set the tag.                                       |

## 10.20 match ip route-source

Use **match ip route-source** command to redistribute the routes whose source IP address matches the access list. Use the **no** form of this command to remove the setting.

**match ip route-source** {*access-list-number* [*access-list-number...* | *access-list-name...*] [*access-list-name* [*access-list-number...*]*access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*]}

**no match ip route-source** [*access-list-number* [*access-list-number...* | *access-list-name...*] [*access-list-name* [*access-list-number...*]*access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*]]

**Parameter description**

| Parameter                           | Description                       |
|-------------------------------------|-----------------------------------|
| <i>access-list-number</i>           | Number of the access list         |
| <i>access-list-name</i>             | Name of the access list           |
| <i>prefix-list prefix-list-name</i> | Specify the prefix list to match. |

**Default**

**configuration** None.

**Command**

**mode** Route map configuration mode.

Multiple access list numbers may follow match ip route-source.

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

#### Usage

#### guidelines

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

In the example below, the OSPF routing protocol redistributes the RIP routes. As long as the source IP address of the RIP route matches the access list 5, the OSPF allows for redistribution.

#### Examples

```
router ospf
redistribute rip subnets route-map redrip
network 192.168.12.0 0.0.0.255 area 0

access-list 5 permit 192.168.100.1

route-map redrip permit 10
match ip route-source 5
```

#### Related commands

| Command                  | Description                                       |
|--------------------------|---------------------------------------------------|
| <b>access-list</b>       | Set the access list.                              |
| <b>match ip address</b>  | Match the IP address in the access list.          |
| <b>match interface</b>   | Match the next-hop interface of the route.        |
| <b>match ip next-hop</b> | Match the next-hop IP address in the access list. |
| <b>match metric</b>      | Match the metric.                                 |
| <b>match route-type</b>  | Match the route type.                             |
| <b>match tag</b>         | Match the tag.                                    |
| <b>set metric</b>        | Set the metric.                                   |
| <b>set metric-type</b>   | Set the metric type.                              |
| <b>set tag</b>           | Set the tag.                                      |

## 10.21 match ipv6 address

Use this command to redistribute the network routes permitted in the IPv6 access list or the IPv6 prefix list. Use the **no** form of this command to delete the setting.

**match ipv6 address** { *access-list-name* } | **prefix-list** *prefix-list-name* }

**no match ipv6 address**

#### Parameter description

| Parameter               | Description              |
|-------------------------|--------------------------|
| <i>access-list-name</i> | Name of the access list. |

|                                                  |                                        |
|--------------------------------------------------|----------------------------------------|
| <code>prefix-list <i>prefix-list-name</i></code> | Specify the IPv6 prefix list to match. |
|--------------------------------------------------|----------------------------------------|

**Default**

**configuration** None

**Command**

**mode** Route map configuration mode

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

**Usage**

**guideline**

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The route map can be configured very flexibly to be used for route redistribution and policy-based routing. No matter how the route map is used, the configuration principle is the same, except that different command sets are used. Even if it is used on the route redistribution, different routing protocols can use different commands with the route map.

The following example enables the OSPF routing protocol to redistribute RIP routes that match access list v6acl, with the default metric being 30.

**Examples**

```

ipv6 router ospf
redistribute rip subnets route-map redrip
ipv6 access-list v6acl
10 permit ipv6 2620::64 any

route-map redrip permit 10
match ipv6 address v6acl
set metric 30
    
```

**commands**

| Command                        | Description                                             |
|--------------------------------|---------------------------------------------------------|
| <b>ipv6 access-list</b>        | Set the IPV6 access list.                               |
| <b>match interface</b>         | Match the next-hop interface of the route.              |
| <b>match ipv6 next-hop</b>     | Match the next-hop address in the IPv6 access list.     |
| <b>match ipvr route-source</b> | Match the route source address in the IPv6 access list. |
| <b>match metric</b>            | Match the route metric.                                 |
| <b>match route-type</b>        | Match the route type.                                   |
| <b>match tag</b>               | Match the route tag.                                    |
| <b>set metric</b>              | Set the metric for route redistribution.                |

|                        |                                        |
|------------------------|----------------------------------------|
| <b>set metric-type</b> | Set the type for route redistribution. |
| <b>set tag</b>         | Set the tag for route redistribution.  |

## 10.22 match ipv6 next-hop

Use this command to redistribute the network routes whose next-hop IP address matches the IPv6 access list or the IPv6 prefix list. Use the **no** form of this command to delete the setting.

**match ipv6 next-hop** { *access-list-name* } | **prefix-list** *prefix-list-name*}

**no match ipv6 next hop**

| Parameter description | Parameter                           | Description                            |
|-----------------------|-------------------------------------|----------------------------------------|
|                       | <i>access-list-name</i>             | Name of the IPv6 access list.          |
|                       | <i>prefix-list prefix-list-name</i> | Specify the IPv6 prefix list to match. |

**Default configuration** None

**Command mode** Route map configuration mode

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

**Usage guideline**

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The route map can be configured very flexibly to be used for route redistribution and policy-based routing. No matter how the route map is used, the configuration principle is the same, except that different command sets are used. Even if it is used on the route redistribution, different routing protocols can use different commands with the route map.

The following example enables the OSPF routing protocol to redistribute RIP routes that only match access list v6acl, with the default metric being 40.

**Examples**

```
ipv6 router ospf
 redistribute rip subnets route-map redrip

ipv6 access-list v6acl
 10 permit ipv6 2620::64 any
```

```
route-map redrip permit 10
match ipv6 address v6acl
set metric 40
```

| <b>match route-type</b>        | Match the route type.                                   |
| <b>match tag</b>               | Match the route tag.                                    |
| <b>set metric</b>              | Set the metric for route redistribution.                |
| <b>set metric-type</b>         | Set the type for route redistribution.                  |
| <b>set tag</b>                 | Set the tag for route redistribution.                   |

### 10.23 match ipv6 route-source

Use this command to redistribute the network routes whose next-hop IP address matches the IPv6 access list or the IPv6 prefix list. Use the **no** form of this command to delete the setting.

**match ipv6 route-source** { *access-list-name* } | **prefix-list** *prefix-list-name* }

**no match ipv6 route-source**

**Parameter description**

| Parameter                           | Description                            |
|-------------------------------------|----------------------------------------|
| <i>access-list-name</i>             | Name of the IPv6 access list.          |
| <i>prefix-list prefix-list-name</i> | Specify the IPv6 prefix list to match. |

**Default**

**configuration** None

**Command**

**mode** Route map configuration mode

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

### Usage guideline

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The route map can be configured very flexibly to be used for route redistribution and policy-based routing. No matter how the route map is used, the configuration principle is the same, except that different command sets are used. Even if it is used on the route redistribution, different routing protocols can use different commands with the route map.

The following example enables the OSPF routing protocol to redistribute RIP routes that only match access list v6acl, with the default metric being 50.

### Examples

```
ipv6 router ospf
redistribute rip subnets route-map redrip

ipv6 access-list v6acl
10 permit ipv6 5200::64 any

route-map redrip permit 10
match ipv6 address v6acl
set metric 50
```

### Related commands

| Command                    | Description                                   |
|----------------------------|-----------------------------------------------|
| <b>ipv6 access-list</b>    | Set the IPV6 access list.                     |
| <b>match interface</b>     | Match the next-hop interface of the route.    |
| <b>match ipv6 address</b>  | Match the IP address in the IPV6 access list. |
| <b>match ipv6 next-hop</b> | Match the next hop in the IPV6 access list.   |
| <b>match metric</b>        | Match the route metric.                       |
| <b>match route-type</b>    | Match the route type.                         |
| <b>match tag</b>           | Match the route tag.                          |
| <b>set metric</b>          | Set the metric for route redistribution.      |
| <b>set metric-type</b>     | Set the type for route redistribution.        |
| <b>set tag</b>             | Set the tag for route redistribution.         |

## 10.24 match metric

Use **match metric** command to redistribute the routes of the specified metric. Use the **no** form of this command to remove the setting.

**match metric** *metric*  
**no match metric**

| Parameter          | Parameter     | Description                                |
|--------------------|---------------|--------------------------------------------|
| <b>description</b> | <i>metric</i> | Route metric, in the range 0 to 4294967295 |

**Default configuration** None.

**Command mode** Route map configuration mode.

**Usage guidelines** You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

In the example below, the OSPF routing protocol redistributes the RIP routes of metric 10.

**Examples**

```
router ospf 1
redistribute rip subnets route-map redrip
network 192.168.12.0 0.0.0.255 area 0

route-map redrip permit 10
match metric 10
```

**Related commands**

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>access-list</b>           | Set the access list.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match interface</b>       | Match the interface.           |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |

| <b>match tag</b>             | Match the tag.                 |
| <b>set metric</b>            | Set the metric.                |
| <b>set metric-type</b>       | Set the metric type.           |
| <b>set tag</b>               | Set the tag.                   |

## 10.25 match origin

Use this command to redistribute the routes whose source IP address is permitted by the ACL in the route map configuration mode. Use the **no** form of this command to remove the setting.

**match origin {egp | igp | incomplete}**

**no match origin [egp | igp | incomplete]**

|                       | Parameter  | Description                                      |
|-----------------------|------------|--------------------------------------------------|
| Parameter description | egp        | Redistribute the routes from the remote EGP.     |
|                       | igp        | Redistribute the routes from the local IGP.      |
|                       | incomplete | Redistribute the routes from an incomplete type. |

### Default

**configuration** None

### Command

**mode** Route map configuration mode

### Usage

**guideline** Use this command to set the origin of the routes to be redistributed. Only one origin can be set.

### Examples

```
Ruijie(config)# route-map MY_MAP 10 permit
Ruijie(config-route-map)# match origin egp
Ruijie(config-route-map)# set community 109
Ruijie(config-route-map)# exit
Ruijie(config)# route-map MAP20 20 permit
Ruijie(config-route-map)# match origin incomplete
Ruijie(config-route-map)# set community no-export
```

|                  | Command                    | Description                  |
|------------------|----------------------------|------------------------------|
| Related commands | <b>match as-path</b>       | Match the AS_PATH attribute. |
|                  | <b>match metric</b>        | Match the metric.            |
|                  | <b>match origin</b>        | Match the source.            |
|                  | <b>set as-path prepend</b> | Set the AS_PATH attribute.   |
|                  | <b>set metric</b>          | Set the metric.              |
|                  | <b>set origin</b>          | Set the source.              |

## 10.26 match route-type

Use this command to redistribute the network routes of the specified type. Use the **no** form of this command to delete the setting.

**match route-type { static | connect | rip | local | internal | external [ type-1 | type-2 ] | level-1 |**

```
level-2 | evpn-type-1 | evpn-type-2 | evpn-type-3 | evpn-type-4 | evpn-type-5 }
no match route-type [ static | connect | rip | local | internal | external [ type-1 | type-2 ] | level-1 |
level-2 | evpn-type-1 | evpn-type-2 | evpn-type-3 | evpn-type-4 | evpn-type-5]
```

### Parameter description

| Parameter                                                                  | Description                                       |
|----------------------------------------------------------------------------|---------------------------------------------------|
| <b>local</b>                                                               | Indicates the local route type.                   |
| <b>static</b>                                                              | Indicates the static route type.                  |
| <b>connect</b>                                                             | Indicates the directly connected route type.      |
| <b>rip</b>                                                                 | Indicates the RIP route type.                     |
| <b>internal</b>                                                            | Indicates the OSPF internal route type.           |
| <b>external</b>                                                            | Indicates the OSPF external route type.           |
| <b>type-1   type-2</b>                                                     | Indicates the OSPF type-1 or type-2 route type.   |
| <b>level-1   level-2</b>                                                   | Indicates the ISIS level-1 or level-2 route type. |
| <b>evpn-type-1   evpn-type-2   evpn-type-3   evpn-type-4   evpn-type-5</b> | 5 route types of BGP EVPN                         |

### Default

**configuration** None

### Command

**mode** Route map configuration mode

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

### Usage

#### guideline

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

In the example below, the RIP routing protocol redistributes only the internal routes in the OSPF routing domain.

### Examples

```
router rip
redistribute ospf route-map redrip
network 192.168.12.0

route-map redrip permit 10
match route-type internal
!
```

|                 | <b>set metric-type</b>       | Set the access list.           |
|                 | <b>set tag</b>               | Match the IP address.          |

## 10.27 match tag

Use this command to redistribute the network routes with the specified tag. Use the **no** form of this command to delete the setting.

**match tag** *tag* [...*tag*]

**no match tag** [*tag* [...*tag*]]

|                              | Parameter  | Description |
|------------------------------|------------|-------------|
| <b>Parameter description</b> | <i>tag</i> | Route tag   |

**Default configuration** None

**Command mode** Route map configuration mode

Multiple tags may follow the match tag command.

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

**Usage guideline** In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

In the example below, the RIP routing protocol redistributes only the routes with tag 50 and 80 in the OSPF routing domain.

**Examples**

```
Ruijie(config)# router rip
Ruijie(config-router)# redistribute ospf 100 route-map redrip
Ruijie(config-router)# network 192.168.12.0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# match tag 50 80
```

**Related commands**

|------------------------------|----------------------------------|
| <b>access-list</b>           | Set the access list.             |
| <b>match ip address</b>      | Match the IP address.            |
| <b>match interface</b>       | Match the next-hop IP interface. |
| <b>match ip route-source</b> | Match the source IP address.     |
| <b>match metric</b>          | Match the metric.                |
| <b>match ip next-hop</b>     | Match the next-hop IP address.   |
| <b>match route-type</b>      | Match the route type.            |
| <b>set metric</b>            | Set the metric.                  |
| <b>set metric-type</b>       | Set the metric type.             |
| <b>set tag</b>               | Set the tag.                     |

## 10.28 memory-lack exit-policy

Use this command to configure a policy to preferentially exit a routing protocol when the memory reaches the lower limit. Use the **no** form of this command to restore the default policy, namely, exit the routing protocol which occupies the largest memory.

**memory-lack exit-policy { bgp | ospf | pim-sm | rip }**

**no memory-lack exit-policy**

**Parameter description**

| Parameter     | Description                                                 |
|---------------|-------------------------------------------------------------|
| <b>bgp</b>    | Preferentially exit BGP when the memory is insufficient.    |
| <b>ospf</b>   | Preferentially exit OSPF when the memory is insufficient.   |
| <b>pim-sm</b> | Preferentially exit PIM-SM when the memory is insufficient. |
| <b>rip</b>    | Preferentially exit RIP when the memory is insufficient.    |

**Default**

By default, the routing protocol which occupies the largest memory exits preferentially.

**Command mode**

Global configuration mode

**Usage**

When the memory reaches the lower limit, you can disable a routing protocol to release the memory to

**guideline** ensure the normal running of other protocols.

When the system runs out of memory, disable a routing protocol which has the minimal impact on the system to ensure the operation of main services.

Configuring the policy to preferentially exit the routing protocols which are disabled cannot help the system release memory.

This command ensures the operation of main services to some extent when the memory is insufficient. If the memory is further consumed, all routing protocols will exit and stop running.

**Examples** The following example configures a policy to preferentially exit the BGP protocol when the memory reaches the lower limit.

```
Ruijie(config)# memory-lack exit-policy bgp
```

| <i>sequence-number</i> | Sequence number of the route map. The policy with a lower sequence number is preferred, so it's noted when setting the sequence number. |

**Default****configuration** None.**Command****mode** Global configuration mode.

At present, the RGOS software primarily uses the route map for route redistribution and policy-based routing.

## 1. Route redistribution control

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

When configuring route maps, pay attention to the following when using the sequence number of a route map:

**Usage**

When you create the first route map policy, if *sequence-number* is not specified, it is 10 by default;

**guidelines**

If only one route map policy exists and *sequence-number* is not specified, no new route map policy will be created, and the existing route map policy will be accessed for configuration;

If more than one route map policy is available, the sequence number of each policy shall be specified; otherwise an error message will be displayed.

## 2. policy-based routing

Policy-based routing refers to a routing mechanism based on user defined policies. Compared with traditional destination IP address-based routing, policy-based routing offers a flexibility for routing based on source IP address, length and port of IP packets. Policy-based routing can apply to the IP packets received on an interface or the IP packets sent from the local device.

Policy-based routing utilizes route map to define routing and forwarding policy. The match command defines packet filtering rule and the set command defines the action for the packets matching the filtering rules. The match command used includes match ip address and match length; the set command includes set ip tos, set ip precedence, set ip dscp, set ip [default] nexthop, set ip next-hop verify-availability, set [default] interface.

**Examples**

The following example enables the OSPF routing protocol to redistribute the RIP routes with the hop count of 4. In the OSPF route domain, the route type is the external route type-1, the default metric is 40 and the tag is 40.

```

!
router ospf
 redistribute rip subnets route-map redrip
 network 192.168.12.0 0.0.0.255 area 0
!
!
route-map redrip permit 10
 match metric 4
 set metric 40
 set metric-type type-1
 set tag 40
    
```

| <b>Related commands</b> | Command      | Description              |
|-------------------------|--------------|--------------------------|
|                         | redistribute | Redistribute the routes. |

### 10.30 send-lifetime

Use this command in the encryption key configuration mode to specify the lifetime of an encryption key in its send direction. Use the no form of this command to restore the default value.

**send-lifetime** *start-time* {infinite | *end-time* | **duration** *seconds*}

**no send-lifetime**

| <b>Parameter description</b> | Parameter                         | Description                                                                                 |
|------------------------------|-----------------------------------|---------------------------------------------------------------------------------------------|
|                              | <i>start-time</i>                 | Start time of the lifetime.                                                                 |
|                              | <b>infinite</b>                   | Indicates that the encryption key is valid for ever.                                        |
|                              | <i>end-time</i>                   | <i>End time of the encryption key. It must be later than the start time.</i>                |
|                              | <b>duration</b><br><i>seconds</i> | Duration of the encryption key after the start time. The value ranges from 1 to 2147483646. |

**Default** infinite

**Command mode** Encryption key configuration mode

**Usage guideline** Use this command to specify the lifetime of an encryption key in its send direction.

**Examples** The following example configures the lifetime from 0:00 on September 9, 2000 to 0:00 on October 12, 2011

```

Ruijie(config)# key chain ripkeys
Ruijie(config-keychain)# key 1
Ruijie(config-keychain-key)# send-lifetime 00:00:00 Sep 9 2000 00:00:00 Dec 12 2011
    
```

**Platform description** -

## 10.31 set aggregator as

Use this command to specify the AS\_PATH attribute for the aggregator of the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set aggregator as** *as-number ip\_addr*

**no set aggregator as** [*as-number ip\_addr*]

| Parameter description | Parameter         | Description                   |
|-----------------------|-------------------|-------------------------------|
|                       | <i>as-number</i>  | AS number of the aggregator.  |
|                       | <i>ip_address</i> | IP address of the aggregator. |

**Default configuration** None

**Command mode** Route map configuration mode

**Usage guideline** Use this command to set the AS\_PATH attribute for the matched routes in the BGP routing domain. Only one group of parameters (as-number, ip-addr) is allowed to set at a time.

### Examples

```
Ruijie(config)# route-map set-as-path
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set aggregator as 3 2.2.2.2
```

| Related commands | Command         | Description                  |
|------------------|-----------------|------------------------------|
|                  | match as-path   | Match the AS_PATH.           |
|                  | match community | Match the community.         |
|                  | match metric    | Match the route metric.      |
|                  | match origin    | Match the route source.      |
|                  | set community   | Set the COMMUNITY attribute. |
|                  | set metric      | Set the metric.              |
|                  | set metric-type | Set the type.                |

### 10.32 set as-path prepend

Use this command to specify the AS\_PATH attribute for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set as-path prepend** *as-number*

**no set as-path prepend**

**Parameter description**

| Parameter        | Description                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> | Indicates number of the AS_PATH attribute to be configured.<br>The AS number ranges from 1 to 4294967295, and 1 to 65535.65535 in dot mode. |

**Default**

**configuration** None

**Command**

**mode** Route map configuration mode

**Usage**

**guideline**

Use this command to configure the AS\_PATH attribute for the matched routes. Up to 10 ASs can be added into the as-path for one time.

**Examples**

```
Ruijie(config)# route-map set-as-path
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set as-path prepend 100 101 102
```

**Related commands**

| Command                | Description                  |
|------------------------|------------------------------|
| <b>match as-path</b>   | Match the AS_PATH.           |
| <b>match community</b> | Match the community.         |
| <b>match metric</b>    | Match the route metric.      |
| <b>match origin</b>    | Match the route source.      |
| <b>set community</b>   | Set the COMMUNITY attribute. |
| <b>set metric</b>      | Set the metric.              |
| <b>set metric-type</b> | Set the type.                |

### 10.33 set atomic-aggregate

Use this command to set the ATOMIC-AGGREGATE attribute for routes.

**set atomic-aggregate**

Use the **no** form of this command to delete existing configuration.

**no set atomic-aggregate**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|     |     |
|-----|-----|
| N/A | N/A |
|-----|-----|

**Defaults** N/A

**Command Mode** Routing map configuration mode

**Default Level** 14

**Usage Guide** This command is used only in the BGP protocol and is used to set the ATOMIC-AGGREGATE attribute for routes.

**Configuration Examples** N/A

## 10.34 set comm-list delete

Use this command to delete the COMMUNITY\_LIST attribute for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set comm-list** *community-list-number* | *community-list-name* **delete**

**no set comm-list** *community-list-number* | *community-list-name* **delete**

|                              | Parameter                    | Description                                                                                                          |
|------------------------------|------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Parameter description</b> | <i>community-list-number</i> | Number of the community list.<br>Standard community list number : 1-99.<br>Extended community list number : 100-199. |
|                              | <i>community-list-name</i>   | Name of the community list, which should be no more than 80 characters.                                              |

**Default configuration** None

**Command mode** Route map configuration mode

**Usage guideline** Use this command to set the community attribute value for the matched routes that will be deleted.

**Examples**

```
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 172.16.233.33 remote-as 120
Ruijie(config-router)# neighbor 172.16.233.33 route-map ROUTEMAPIN in
Ruijie(config-router)# neighbor 172.16.233.33 route-map ROUTEMAPOUT out
```

```

Ruijie(config-router)# exit
Ruijie(config)# ip community-list 500 permit 100:10
Ruijie(config)# ip community-list 500 permit 100:20
Ruijie(config)# ip community-list 120 deny 100:50
Ruijie(config)# ip community-list 120 permit 100:.*
Ruijie(config)# route-map ROUTEMAPIN permit 10
Ruijie(config-route-map)# set comm-list 500 delete
Ruijie(config-route-map)# exit
Ruijie(config)# route-map ROUTEMAPOUT permit 10
Ruijie(config-route-map)# set comm-list 120 delete

```

#### Related commands

| Command                     | Description                                              |
|-----------------------------|----------------------------------------------------------|
| <b>match as-path</b>        | Match the AS_PATH attribute value.                       |
| <b>match metric</b>         | Match the metric.                                        |
| <b>match origin</b>         | Match the source.                                        |
| <b>set as-path prepend</b>  | Set the AS_PATH attribute.                               |
| <b>set local-preference</b> | Set the local priority of the route to be redistributed. |
| <b>set metric-type</b>      | Set the metric type.                                     |

## 10.35 set community

Use this command to specify the community for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set community** {*community-number*[*community-number*...]} [**additive** | **none**]

**no set community**

#### Parameter description

| Parameter               | Description                                                                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>community-number</i> | Community number in the form of AA:NN or a large numeral. In addition, it can be well-known community attributes like internet, local-AS, no-export and no-advertise. |
| additive                | Increase on the original COMMUNITY attribute.                                                                                                                         |
| none                    | Set the community attribute as blank.                                                                                                                                 |

#### Default

**configuration** None

#### Command

**mode** Route map configuration mode

**Usage**

**guideline** Use this command to set the community attribute for the matched route.

**Examples**

```
Ruijie(config)# route-map SET_COMMUNITY 10 permit
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set community 109:10
Ruijie(config-route-map)# exit
Ruijie(config)# route-map SET_COMMUNITY 20 permit
Ruijie(config-route-map)# match as-path 2
Ruijie(config-route-map)# set community no-export
```

**Related commands**

| Command                    | Description                |
|----------------------------|----------------------------|
| <b>match as-path</b>       | Match the AS_PATH.         |
| <b>match community</b>     | Match the community.       |
| <b>match metric</b>        | Match the metric.          |
| <b>match origin</b>        | Match the source.          |
| <b>set as-path prepend</b> | Set the AS_PATH attribute. |
| <b>set origin</b>          | Set the source.            |
| <b>set metric-type</b>     | Set the metric type.       |

## 10.36 set dampening

Use this command to specify the dampening parameters for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set dampening** *half-life reuse suppress max-suppress-time*

**no set dampening**

**Parameter description**

| Parameter                | Description                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <i>half-life</i>         | Half dampening life for the reachable or unreachable route in the range of 1 to 45 minutes, 15 minutes by default                 |
| <i>reuse</i>             | When the route penalty is lower than this value, the route suppression is released. It is in the range 1 to 20000, 750 by default |
| <i>suppress</i>          | When the route penalty is higher than this value, the route is suppressed. It is in the range 1 to 20000, 2000 by default         |
| <i>max-suppress-time</i> | Maximum duration a route can be suppressed in the range 1 to 20000 minutes, 4* half-life by default.                              |

**Default**

**configuration** None

**Command**

**mode** Route map configuration mode

**Usage**

**guideline** Use this command to set the dampening parameter for the matched routes.

**Examples**

```
Ruijie(config)# route-map tag
Ruijie(config-route-map)# match as path 10
Ruijie(config-route-map)# set dampening 30 1500 10000 120
Ruijie(config-route-map)# exit
Ruijie(config)# router bgp 100
Ruijie(config-router)# neighbor 172.16.233.52 route-map tag in
```

**Related commands**

| Command                     | Description                                              |
|-----------------------------|----------------------------------------------------------|
| <b>match as-path</b>        | Match the AS_PATH value.                                 |
| <b>match community</b>      | Match the community.                                     |
| <b>match metric</b>         | Match the metric.                                        |
| <b>match origin</b>         | Match the source.                                        |
| <b>set as-path prepend</b>  | Set the AS_PATH attribute.                               |
| <b>set metric</b>           | Set the metric.                                          |
| <b>set local-preference</b> | Set the local priority of the route to be redistributed. |

## 10.37 set extcomm-list delete

Use this command to delete all extcommunity values in the extcommunity list that meet the match rules. Use the **no** form of this command to delete the configuration.

**set extcomm-list** { *extcommunity-list-number* | *extcommunity-list-name* } **delete**

**no set extcomm-list** { *extcommunity-list-number* | *extcommunity-list-name* } **delete**

**Parameter description**

| Parameter                       | Description                                                                                                      |
|---------------------------------|------------------------------------------------------------------------------------------------------------------|
| <i>extcommunity-list-number</i> | <i>extcommunity-list-number</i><br>Standard list: ranges from 1 to 99.<br>Expanded list: ranges from 100 to 199. |
| <i>extcommunity-list-name</i>   | <i>extcommunity-list-name</i><br>It consists of a maximum of 80 characters.                                      |

**Default**

-

**Command mode**

Route map configuration mode.

**Usage**

This command is used to delete the **extcommunity-list**.

**guideline** This command applies only to policy route configuration.

**Examples**

```
Ruijie(config)# router bgp 65530
Ruijie(config-router)# neighbor 172.16.233.33 remote-as 65531
Ruijie(config-router)# address-family vpnv4 unicast
Ruijie(config-router-af)# neighbor 172.16.233.33 activate
Ruijie(config-router-af)# neighbor 172.16.233.33 route-map ROUTEMAPIN in
Ruijie(config-router-af)# neighbor 172.16.233.33 route-map ROUTEMAPOUT out
Ruijie(config-router)# exit
Ruijie(config)# ip extcommunity-list 10 permit rt 100:10
Ruijie(config)# ip extcommunity-list 10 permit rt 100:20
Ruijie(config)# ip extcommunity-list 120 deny 100:50
Ruijie(config)# ip extcommunity-list 120 permit 100:.*
Ruijie(config)# route-map ROUTEMAPIN permit 10
Ruijie(config-route-map)# set extcomm-list 10 delete
Ruijie(config-route-map)# exit
Ruijie(config)# route-map ROUTEMAPOUT permit 10
Ruijie(config-route-map)# set extcomm-list 120 delete
```

**Related command**

| Command                        | Description                             |
|--------------------------------|-----------------------------------------|
| <b>ip extcommunity-list</b>    | Configure an <b>extcommunity-list</b> . |
| <b>match as-path</b>           | Match the AS_PATH value                 |
| <b>match metric</b>            | Match the metric.                       |
| <b>match origin</b>            | Match the source.                       |
| <b>set as-path prepend</b>     | Set the AS_PATH attribute.              |
| <b>set extcomm-list delete</b> | Set delete <b>extcommunity-list</b> .   |
| <b>set local-preference</b>    | Set local preference for a reroute.     |

**Platform description** -

## 10.38 set extcommunity

Use this command to specify the extended COMMUNITY attribute for the routes that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set extcommunity** {rt *extend-community-value* | soo *extend-community-value*}  
**no set extcommunity** {rt | soo }

**Parameter description**

| Parameter | Description                                              |
|-----------|----------------------------------------------------------|
| rt        | Specify the extended community value in the form of RT.  |
| soo       | Specify the extended community value in the form of SOO. |

|                               |                           |
|-------------------------------|---------------------------|
| <i>extend-community-value</i> | Extended community value. |
|-------------------------------|---------------------------|

**Default** None

**Command mode** Route map configuration mode

**Usage guideline** Use this command to set the extended community attribute for the matched route.

### Examples

```
Ruijie(config)# access-list 2 permit 192.168.78.0 255.255.255.0
Ruijie(config)# route-map MAP_NAME permit 10
Ruijie(config-route-map)# match ip-address 2
Ruijie(config-route-map)# set extcommunity rt 100:2
```

### Related commands

| Command                    | Description                |
|----------------------------|----------------------------|
| <b>match as-path</b>       | Match the AS_PATH value    |
| <b>match community</b>     | Match the community.       |
| <b>match metric</b>        | Match the metric.          |
| <b>match origin</b>        | Match the source.          |
| <b>set as-path prepend</b> | Set the AS_PATH attribute. |
| <b>set metric</b>          | Set the metric.            |
| <b>set metric-type</b>     | Set the metric type.       |

## 10.39 set fast-reroute

Use this command to specify a backup outgoing fast reroute and a backup next-hop for routes that meet the match conditions. Use the no form of this command to delete the configuration.

**set fast-reroute backup-interface** *interface-type interface-number* [ **backup-nexthop** *ip-address* ]

**no set fast-reroute**

### Parameter description

| Parameter                              | Description                |
|----------------------------------------|----------------------------|
| <i>interface-type interface-number</i> | Backup outgoing interface. |
| <i>ip-address</i>                      | Backup next-hop.           |

**Default** -

**Command mode** Route map configuration mode.

**Usage guideline** Use this command to configure IP FRR backup outgoing interface and backup next-hop. The current software version supports only one backup route. This command supports only one set of the two

parameters.

This command is used for fast reroute configuration.

 IP FRR backup routes must not be direct-connection or local host routes.

**Examples**

```
Ruijie(config)# access-list 2 permit 192.168.78.0 255.255.255.0
Ruijie(config)# route-map frr permit 10
Ruijie(config-route-map)# match ip-address 2
Ruijie(config-route-map)# set fast-reroute backup-interface GigabitEthernet
0/1 backup-nexthop 192.168.1.2
```

**Related command**

| Command                 | Description            |
|-------------------------|------------------------|
| <b>match ip-address</b> | Match IP address list. |

**Platform description**

## 10.40 set ip default next-hop

Use this command to specify the default next-hop IP address for the packets that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set ip default next-hop** *ip-address* [ *weight* ] [ ...*ip-address* [ *weight* ] ]

**no set ip default next-hop** [ *ip-address* [ *weight* ] [ ...*ip-address* [ *weight* ] ] ]

**Parameter description**

| Parameter         | Description                 |
|-------------------|-----------------------------|
| <i>ip-address</i> | IP address of the next hop. |
| <i>weight</i>     | Weight of the next hop.     |

**Default configuration**

None

**Command mode**

Route map configuration mode

This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In the former mode, the system implements WCMP load balancing according to the weight inputted.

**Usage guideline**

Up to 32 IP addresses may follow the set ip default next-hop command.

If a weight follows ip address, up to 4 next hop IP addresses can be configured.

Note: If a weight follows any next-hop, the operation mode of this command will be automatically switched to the WCMP load balancing mode. In this mode, the weight of those next hop IP addresses whose weight is not configured is 1 by default.

Differences between `set ip next-hop` and `set ip default next-hop`: After the `set ip next-hop` command is configured, the policy-based routing takes precedence over the routing table; while after the `set ip default next-hop` command is configured, the routing table takes precedence over the policy-based routing.

Use this command to customize a default route for a specified user. If the software fails to find the forwarding route, the packet will be forwarded to the next hop set with this command.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded through the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

A route-map policy may contain multiple set operations.

The following example forwards the packets from two different nodes through different routes.

For the messages received on the synchronous interface 1 from 1.1.1.1, if the software cannot find the forwarding route, they are forwarded to device 6.6.6.6. For the messages received from 2.2.2.2, if the software cannot find the forwarding route, they are forwarded to device 7.7.7.7. The other messages will be discarded if the software cannot find the forwarding route.

### Examples

```
Ruijie(config)#access-list 1 permit 1.1.1.1 0.0.0.0
Ruijie(config)#access-list 2 permit 2.2.2.2 0.0.0.0
Ruijie(config)#interface async 1
Ruijie(config-if)#ip policy route-map equal-access
Ruijie(config)#route-map equal-access permit 10
Ruijie(config- route-map)#match ip address 1
Ruijie(config-route-map)#set ip default next-hop 6.6.6.6
Ruijie(config)#route-map equal-access permit 20
Ruijie(config-route-map)#match ip address 2
Ruijie(config-route-map)#set ip default next-hop 7.7.7.7
Ruijie(config)#route-map equal-access permit 30
Ruijie(config- route-map)#set default interface null 0
```

|                  | <b>set ip precedence</b>     | Set the priority of the packets.    |

## 10.42 set ip next-hop

Use this command to specify the next-hop IP address for the packets that meet the matching rule. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set ip next-hop** *ip-address* [ *weight* ] [ ...*ip-address* [ *weight* ] ]

**no set ip next-hop** [ *ip-address* [ *weight* ] [ ...*ip-address* [ *weight* ] ] ]

| Parameter   | Parameter         | Description                            |
|-------------|-------------------|----------------------------------------|
| description | <i>ip-address</i> | Indicates the next-hop IP address.     |
|             | <i>weight</i>     | Indicates the weight of this next hop. |

**Default** None

**configuration****Command****mode** Route map configuration mode

This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In the former mode, the system implements WCMP load balancing according to the weight entered by the user.

Multiple IP addresses may follow set ip next-hop and the number of addresses should be less than 32.

---

 If weight follows any next-hop, the operation mode of this command will be automatically switched to the WCMP load balancing mode. In the WCMP load balancing mode, for the nexthop address without configuring the corresponding weight, the weight is 1 by default.

---

**Usage  
guideline**

If weight follows ip address, up to 4 next hop addresses can be configured.

This command can be used to set different routes for the traffic that meets different match rule. If multiple IP addresses are configured, they can be used in turn.

Policy-based routing is a packet forwarding mechanism more flexible than the routing based on the target network. After the policy-based routing is used, the device will decide how to process the packets that need be routed according to the route map, which decides the next-hop device of the packets.

To use the policy-based routing, you must specify the route map for it and create the route map. A route map contains multiple policies, and each policy defines one or more match rules and the corresponding operations. After policy-based routing is applied to an interface, the packets received by the interface will be checked. The packets that do not match any policy in the route map will be forwarded to the usual route. The packets that match a policy in the route map will be processed according to the operation defined in the policy.

A route-map policy may contain multiple set operations.

The following example enables policy-based routing on serial 1/0. When the interface receives the packets from 10.0.0.0/8, they will be sent to 192.168.100.1; when the interface receives the packets from 172.16.0.0/16, they will be sent to 172.16.100.1; all other packets will be discarded.

**Examples**

```
Ruijie(config)#interface serial 1/0
Ruijie(config-if)#ip policy route-map load-balance
Ruijie(config)#access-list 10 permit 10.0.0.0 0.255.255.255
Ruijie(config)#access-list 20 permit 172.16.0.0 0.0.255.255
Ruijie(config)#route-map load-balance permit 10
Ruijie(config-route-map)#match ip address 10
Ruijie(config-route-map)#set ip next-hop 192.168.100.1
Ruijie(config)#route-map load-balance permit 20
Ruijie(config-route-map)#match ip address 20
Ruijie(config-route-map)#set ip next-hop 172.16.100.1
Ruijie(config)#route-map load-balance permit 30
Ruijie(config-route-map)#set interface Null 0
```

| Related<br>commands | Command                        | Description                         |
|---------------------|--------------------------------|-------------------------------------|
|                     | <b>route-map</b>               | Define the route map.               |
|                     | <b>match ip address</b>        | Match the IP address.               |
|                     | <b>set default interface</b>   | Set the default outgoing interface. |
|                     | <b>set interface</b>           | Set the outgoing interface.         |
|                     | <b>set ip default next-hop</b> | Set the default next hop.           |
|                     | <b>set ip precedence</b>       | Set the priority of the packets.    |

## 10.43 set ip next-hop recursive

Use this command to specify the recursive next-hop IP address for data packets that match a rule.

**set ip next-hop recursive** *ip-address*

Use the **no** form of this command to delete the configured next-hop IP address.

**no set ip next-hop recursive**

| Parameter<br>Description | Parameter         | Description |
|--------------------------|-------------------|-------------|
|                          | <i>ip-address</i> |             |

**Defaults** N/A

**Command Mode** Routing map configuration mode

**Default Level** 14

**Usage Guide** This command is used only to configure PBR. Only one **set ip next-hop recursive** *ip-address* command can be configured in one routing submap policy. According to the policy, only static or dynamic routes that have an egress and next-hop IP address can be recursed. A route can be recursed to 32 next-hop IP addresses. Only one static route can be recursed to the next hop IP address.

**Examples** The following example enables PBR on Interface serial 1/0. The interface sends the data packets from the source IP address of 10.0.0.0/8 to the recursive next-hop IP address 192.168.100.1, sends the traffic from the source network 172.16.0.0/16 to the recursive next-hop IP address 172.16.100.1, and forwards other data traffic via common routes.

```
Ruijie(config)#interface serial 1/0
Ruijie(config-if)#ip policy route-map load-balance
Ruijie(config)#access-list 10 permit 10.0.0.0 0.255.255.255
Ruijie(config)#access-list 20 permit 172.16.0.0 0.0.255.255
Ruijie(config)#route-map load-balance permit 10
```

```
Ruijie(config-route-map)#match ip address 10
Ruijie(config-route-map)#set ip next-hop recursive 192.168.100.1
Ruijie(config)#route-map load-balance permit 20
Ruijie(config-route-map)#match ip address 20
Ruijie(config-route-map)#set ip next-hop recursive 172.16.100.1
```

## 10.44 set ip next-hop verify-availability

Use this command to verify the availability of the next hop IP address for the packets that meet the matching rule. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set ip next-hop verify-availability** *ip-address* [**track** *track-obj-number* | **bfd** *interface-type interface-number gateway*]

**no set ip next-hop verify-availability** *ip-address* [**track** *track-obj-number* | **bfd** *interface-type interface-number gateway*]

### Parameter description

| Parameter               | Description                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i>       | Indicates the next-hop IP address.                                                                                                                                                              |
| <b>track</b>            | Judges whether the next hop is effective by using <i>Track</i> .                                                                                                                                |
| <i>track-object-num</i> | Indicates the track object number.                                                                                                                                                              |
| <b>bfd</b>              | Indicates that BFD is used for neighbor detection.                                                                                                                                              |
| <i>interface-type</i>   | Configures the interface type.                                                                                                                                                                  |
| <i>interface-number</i> | Configures the interface number.                                                                                                                                                                |
| <i>gateway</i>          | Configures the gateway IP address, which is the neighbor IP address of BFD. If the next hop is configured as the neighbor, BFD will be used to detect the accessibility of the forwarding path. |

**Default configuration** None

**Command mode** Route map configuration mode

**Usage guideline** None

**Examples** The following example verifies the availability of the next hop IP address being 192.168.1.2 and the number of the object to be tracked to 1.

```
Ruijie(config)#route-map rmap permit 10
Ruijie(config-route-map)#set ip next-hop verify-availability 192.168.1.2
```

```
track 1
```

Defaults N/A

Command mode Route map configuration mode

**Usage  
guideline**

With different precedence values for the IP packet head configured, the IP packets matching the PBR routing are sent according to the different precedence values.

Multiple set ip precedence commands can be executed in the route map configuration rule, but only the last one takes effect, and the precedence will be specified for the head of the IP packet matched the PBR.

The following example sets the precedence of the packet with the source IP address 192.168.217.68 received at the interface FastEthernet 0/0 as 4:

**Examples**

```
Ruijie(config)#access-list 1 permit 192.168.217.68 0.0.0.0
Ruijie(config)#route-map name
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip precedence 4
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ip policy route-map name
```

**Related  
commands**

| <b>set ip tos</b>            | Set the tos for the IP packet head.           |

## 10.46 set ip tos

Use this command to set the tos of the IP head of the packet matching the rule in the route map configuration mode. Use the **no** form of this command to remove the configured tos setting.

**set ip tos** {<0-15> | *max-reliability* | *max-throughput* | *min-delay* | *min-monetary-cost* | *normal* }

**no set ip tos**

**Parameter  
Description**

| Parameter                                                               | Description                                                                  |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------|
| <i>number</i>                                                           | Indicates the TOS value of an IP header with a number, ranging from 0 to 15. |
| <b>max-reliability</b>  <br><b>max-throughput</b>  <br><b>min-delay</b> | Priority of an IP header.                                                    |

|                                       |
|---------------------------------------|
| <b>min-monetary-cost  <br/>normal</b> |
|---------------------------------------|

**Defaults** N/A

**Command mode** Route map configuration mode

**Usage guideline** With different TOS values for the IP packet head configured, the IP packets matching the PBR routing are transmitted with different service qualities.  
The TOS value will be specified for the head of the IP packet matched the PBR.

The following example sets the TOS value of the packet with the source IP address 192.168.217.68 received at the interface FastEthernet 0/0 as 4:

**Examples**

```
Ruijie(config)#access-list 1 permit 192.168.217.68 0.0.0.0
Ruijie(config)#route-map name
Ruijie(config-route-map)#match ip address 1
Ruijie(config-route-map)#set ip tos 4
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ip policy route-map name
```

**Related commands**

| Command                      | Description                                   |
|------------------------------|-----------------------------------------------|
| <b>match interface</b>       | Match the next-hop interface.                 |
| <b>match ip address</b>      | Match the IP address in the ACL.              |
| <b>match ip next-hop</b>     | Match the next-hop IP address in the ACL.     |
| <b>match ip route-source</b> | Match the route source IP address in the ACL. |
| <b>match metric</b>          | Match the route metric value.                 |
| <b>match route-type</b>      | Match the route type.                         |
| <b>match tag</b>             | Match the route tag value.                    |
| <b>set metric-type</b>       | Set the type of redistributed route.          |
| <b>set tag</b>               | Set the tag value of redistributed route.     |
| <b>set ip precedence</b>     | Set the precedence for the IP packet head.    |

## 10.47 set ipv6 default next-hop

Use this command to specify the default next-hop IPv6 address for the IPv6 packets that match the rule in the route map configuration mode. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set ipv6 default next-hop** *global-ipv6-address* [ *weight* ] [ *global-ipv6-address* [ *weight* ] ... ]

**no set ipv6 default next-hop** *global-ipv6-address* [ *weight* ] [ *global-ipv6-address* [ *weight* ] ... ]

**Parameter**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                    |                            |                                                                                                                                                |
|--------------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>description</b> | <b>vrf</b> <i>vrf-name</i> | The next hop address belongs to the specified VRF which must be the configured IPv6 address family multi-protocol VRF.                         |
|                    | <b>global</b>              | The next hop address belongs to the global.                                                                                                    |
|                    | <i>global-ipv6-address</i> | Indicates the next-hop IPv6 address for packet forwarding. The next-hop router must be a neighbor router.                                      |
|                    | <i>weight</i>              | Indicates the weight in the load balancing mode, ranging from 1 to 8. A larger value means larger packet traffic to be shared by the next hop. |

**Default****configuration** None**Command****mode** Route map configuration mode

With the policy-based routing applied to the interface, for the IPv6 packets matching the corresponding rules, if the usual route (that is the non default route) with the destination of this packet is not in the routing table, this packet will be forwarded to the next hop specified by the `set ipv6 default next-hop` command. Otherwise it is forwarded through the usual route. Noted that the match rule should be the IPv6 corresponded. If the **vrf** *vrf-name* parameter is specified, packets are forwarded across different VRF instances. If the **global** parameter is specified, packets are forwarded from the VRF instance to a public network. If [**vrf** *vrf-name* | **global**] is not specified, IPv6 packets are sent to the next hop of the VRF instance same as that of the current hop.

**Usage****guideline**

Packets select the egress from the policy-based routing and routing table in following priority:

```
set ipv6 next-hop;
usual route (the non default route)
set ipv6 default next-hop
default route.
```

For the switches, this function does not take effect if the mask length is beyond 64.

---

If this command and the `set ipv6 next-hop verify-availability` are both configured, the next hop set by the `set ipv6 next-hop verify-availability` command will take effect preferentially

---

**Examples**

The following example sets the default next hop of the packet with destination address `2001:0db8:2001:1760::/64` received at the interface `fastEthernet 0/0` as `2002:0db8:2003:1::95`

```
Ruijie(config)# ipv6 access-list acl_for_pbr
Ruijie(config-ipv6-acl)#permit ipv6 any 2001:0db8:2001:1760::/64
Ruijie(config)#route-map rm_if_0_0
```

```
Ruijie(config-route-map)#match ipv6 address acl_for_pbr
Ruijie(config-route-map)# set ipv6 default next-hop
2002:0db8:2003:1::95
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ipv6 policy route-map rm_if_0_0
```

|                  | Command                      | Description                                    |
|------------------|------------------------------|------------------------------------------------|
| Related commands | <b>match ipv6 address</b>    | Set the matching rule of policy-based routing. |
|                  | <b>ipv6 policy route-map</b> | Use the policy-based routing on the interface. |
|                  | <b>set ipv6 next-hop</b>     | Set the next hop of the policy-based routing.  |

**Platform description** N/A

## 10.48 set ipv6 next-hop

Use this command to specify the next-hop IPv6 address for the packets that meet the matching rule. Use the **no** form of this command to remove the setting. This command is only used to configure policy-based routing.

**set ipv6 next-hop** *global-ipv6-address* [weight] [...*global-ipv6-address* [weight]]

**no set ip next-hop** *global-ipv6-address* [weight] [...*global-ipv6-address* [weight]]

|                       | Parameter                  | Description                                                                      |
|-----------------------|----------------------------|----------------------------------------------------------------------------------|
| Parameter description | <i>global-ipv6-address</i> | IPv6 address of the next hop. The next hop router should be the neighbor router. |
|                       | <i>weight</i>              | Weight of the next hop in the load balancing mode, in the range of 1 to 8.       |

**Default configuration** None

**Command mode** Route map configuration mode

This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In the former mode, the system implements WCMP load balancing according to the weight entered by the user.

Multiple IP addresses may follow set ip next-hop and the number of addresses should be less than 32.

**Usage guideline** If weight follows ip address, up to 4 next hop addresses can be configured. If the parameter *vrf vrf-name* is specified, packets forwarding will be across the VRF. The packets will be forwarded from VRF to public network with the parameter *global* specified. If no [*vrf vrf-name* | *global*] is specified, forwarding the IPv6 packets will inherit the VRF, that is the nexthop belongs to the VRF that receives this IPv6 packets.

 If weight follows any next-hop, the operation mode of this command will be automatically switched to the WCMP load balancing mode. In the WCMP load balancing mode, for the nexthop address without configuring the corresponding weight, the weight is 1 by default.

When the packets select the egress from the policy-based routing and routing table, the priorities are as bellows.

- set ipv6 next-hop;
- usual route (the non default route)
- set ipv6 default next-hop
- Default route.

The following examle sets the next hop of the packet with destination address *2001:0db8:2001:1760::/64* received at the interface *fastEthernet 0/0* as *2002:0db8:2003:1::95*

**Examples**

```
Ruijie(config)# ipv6 access-list acl_for_pbr
Ruijie(config-ipv6-acl)#permit ipv6 any 2001:0db8:2001:1760::/64
Ruijie(config)#route-map rm_if_0_0
Ruijie(config-route-map)#match ipv6 address acl_for_pbr
Ruijie(config-route-map)# set ipv6 next-hop
2002:0db8:2003:1::95
Ruijie(config)#interface FastEthernet 0/0
Ruijie(config-if)#ipv6 policy route-map rm_if_0_0
```

**Related commands**

| Command                      | Description                                    |
|------------------------------|------------------------------------------------|
| <b>match ipv6 address</b>    | Set the matching rule of policy-based routing. |
| <b>ipv6 policy route-map</b> | Use the policy-based routing on the interface. |
| <b>set ipv6 next-hop</b>     | Set the next hop of the policy-based routing.  |

**Platform description**

N/A

### 10.49 set ipv6 next-hop verify-availability

Use this command to determine the availability of the next-hop IP address.

**set ipv6 next-hop verify-availability** *global-ipv6-address* [**track** *track-obj-number* | **bfd** *interface-type interface-number gateway*]

Use the **no** form of this command to delete existing configuration.

**no set ip next-hop verify-availability** *global-ipv6-address* [**track** *track-obj-number* | **bfd** *interface-type interface-number gateway*]

**Parameter**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

| Description                |                                                                                                                                                                                                |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>global-ipv6-address</i> | Specifies the next-hop IPv6 address.                                                                                                                                                           |
| <b>track</b>               | Detects whether the next hop is effective by using the tracking method.                                                                                                                        |
| <i>track-obj-number</i>    | Specifies the tracking object number.                                                                                                                                                          |
| <b>bfd</b>                 | Conducts neighbor detection by using BFD.                                                                                                                                                      |
| <i>interface-type</i>      | Specifies the interface type.                                                                                                                                                                  |
| <i>interface-number</i>    | Specifies the interface number.                                                                                                                                                                |
| <i>gateway</i>             | Specifies the gateway IPv6 address, that is, IPv6 address of the BFD neighbor. If the configured next hop is the neighbor, the availability of the forwarding path will be detected using BFD. |

**Defaults** N/A

**Command Mode** Routing map configuration mode

**Default Level** 14

**Usage Guide** This command is used only to configure PBR.

**Examples** The following example enables the PBR support for BFD and detects the forwarding path to the neighbor 2001:1::2 via BFD.

```
Ruijie(config)# route-map rmap permit 10
Ruijie(config-route-map)# set ipv6 next-hop verify-availability 2001:1::2 bfd
FastEthernet 0/1 2001:1::2
```

## 10.50 set ipv6 precedence

Use this command to set the precedence of the IPv6 head of the packet matching the rule in the route map configuration mode. Use the **no** form of this command to remove the configured precedence setting.

**set ipv6 precedence** {number | *critical* | *flash* | *flash-override* | *immediate* | *internet* | *network* | *priority* | *routine* }

**no set ipv6 precedence**

| Parameter description | Parameter                                                                                                                                       | Description                           |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
|                       | <i>critical</i> , <i>flash</i> , <i>flash-override</i> , <i>immediate</i> , <i>internet</i> , <i>network</i> , <i>priority</i> , <i>routine</i> | The precedence type of the IPv6 head. |
|                       | number                                                                                                                                          | The configurable precedence range.    |

**Default configuration** N/A

**Command**

**mode** Route map configuration mode

**Usage****guideline**

The following example sets the precedence of IPv6 packet head as 3:

Configure route-map.

**Examples**

```
Ruijie(config)#route-map pbr-aaa permit 10
```

```
Ruijie(config-route-map)# set ipv6 precedence 3
```

Or

```
Ruijie(config-route-map)# set ipv6 precedence immediate
```

**Related commands**

**Platform**

**description** N/A

## 10.51 set level

Use this command to set the level of the area where the routes matching the rule are redistributed in the route map configuration command. Use the **no** form of this command to remove the setting.

**set level {level-1 | level-2 | level-1-2 | stub-area | backbone}**

**no set level**

**Parameter Description**

| Parameter        | Description                                                                         |
|------------------|-------------------------------------------------------------------------------------|
| <b>level-1</b>   | Indicates that the re-distribution route is advertised to ISIS Level 1.             |
| <b>level-2</b>   | Indicates that the re-distribution route is advertised to ISIS Level 2.             |
| <b>level-1-2</b> | Indicates that the re-distribution route is advertised to ISIS Level 1 and Level 2. |
| <b>stub-area</b> | Indicates that the re-distribution route is advertised to OSPF Stub Area.           |
| <b>backbone</b>  | Indicates that the re-distribution route is advertised to the OSPF backbone         |

|  |       |
|--|-------|
|  | area. |
|--|-------|

**Default configuration** None

**Command mode** Route map configuration mode

In the example below, the OSPF routing protocol redistributes the RIP protocol to the backbone area.

**Examples**

```
Ruijie(config)# router ospf
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# set level backbone
```

**Related commands**

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |
| <b>match metric</b>          | Match the metric.              |
| <b>match route-type</b>      | Match the route type.          |
| <b>match tag</b>             | Match the tag.                 |
| <b>set metric-type</b>       | Set the metric type.           |
| <b>set tag</b>               | Set the tag.                   |

## 10.52 set local-preference

Use this command to set the **LOCAL\_PREFERENCE** value for the routes to be redistributed in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set local-preference** *number*  
**no set local-preference**

**Parameter description**

| Parameter     | Description                                   |
|---------------|-----------------------------------------------|
| <i>number</i> | Local priority metric ranging 1 to 4294967295 |

**Default configuration** None

**Command**

**mode** Route map configuration mode

**Usage guideline** Use this command to set the local preference for the matched routes. Only one local preference can be set.

**Examples**

```
Ruijie(config)# route-map SET_PREF permit 10
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set local-preference 6800
Ruijie(config-route-map)# exit
Ruijie(config)# route-map SET_PREF permit 20
Ruijie(config-route-map)# match as-path 2
Ruijie(config-route-map)# set local-preference 50
```

**Related commands**

|----------------------------|------------------------------|
| <b>match as-path</b>       | Match the AS_PATH attribute. |
| <b>match metric</b>        | Match the route metric.      |
| <b>match origin</b>        | Match the source.            |
| <b>set as-path prepend</b> | Set the AS_PATH attribute.   |
| <b>set metric</b>          | Set the metric.              |
| <b>set metric-type</b>     | Set the metric type.         |

## 10.53 set metric

Use **set metric** to set the metric for the routes to be redistributed. Use the **no** form of this command to remove the setting.

**set metric** [**+** *metric-value* | **-** *metric-value* | *metric-value*]

**no set metric**

**Parameter description**

| Parameter           | Description                                        |
|---------------------|----------------------------------------------------|
| <b>+</b>            | Increase based on the metric of the original route |
| <b>-</b>            | Decrease based on the metric of the original route |
| <i>metric-value</i> | Metric for the route to be redistributed           |

**Default**

**configuration** The default metric for route redistribution varies with the routing protocol.

**Command**

**mode** Route map configuration mode

You should set the metric according to the actual network topology, because the routing depends on the metric of routes. Attentions should be paid to the upper and lower limits of the routing protocols when you execute the `set metric`, `+ metric` or `- metric` commands. When the RIP protocol redistributes the routes of other protocols, the range of the metric after increase or decrease is 1 to 16.

You can redistribute the routes from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

For route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

One or more match or set commands can be executed to configure a route map. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The following example enables the OSPF routing protocol to redistribute the RIP routes and sets the default metric to 40.

```
Ruijie(config)# router ospf
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# set metric 40
```

### Usage guideline

### Related commands

| Command                            | Description                    |
|------------------------------------|--------------------------------|
| <code>match interface</code>       | Match the interface.           |
| <code>match ip address</code>      | Match the IP address.          |
| <code>match ip next-hop</code>     | Match the next-hop IP address. |
| <code>match ip route-source</code> | Match the source IP address.   |
| <code>match metric</code>          | Match the metric.              |
| <code>match route-type</code>      | Match the route type.          |
| <code>match tag</code>             | Match the tag.                 |
| <code>set metric-type</code>       | Set the metric type.           |
| <code>set tag</code>               | Set the tag.                   |

## 10.54 set metric-type

Use `set metric-type` to set the type of the routes to be redistributed. Use the `no` form of this command to remove the setting.

`set metric-type type`

`no set metric-type`

| Parameter                                   | Description                                                                                                                  |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameter description</b><br><i>type</i> | Type of the routes to be redistributed. At present, you can set the type of the routes that the OSPF protocol redistributes. |

**Default configuration****Command**

**mode** Route map configuration mode

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

**Usage guideline**

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The following example enables the OSPF routing protocol to redistribute the RIP route and sets the type as type-1.

**Examples**

```
Ruijie(config)# router ospf
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# set metric-type type-1
```

**Related commands**

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |
| <b>match metric</b>          | Match the metric.              |
| <b>match route-type</b>      | Match the route type.          |
| <b>match tag</b>             | Match the tag.                 |
| <b>set metric</b>            | Set the metric.                |
| <b>set tag</b>               | Set the tag.                   |

## 10.55 set next-hop

Use this command to specify the next-hop IP address for the routes that match the rule. Use the **no** form of this command to remove the setting. This command is only used to configure routing policies.

**set next-hop** *ip-address*

**no set next-hop**

| Parameter   | Parameter         | Description                 |
|-------------|-------------------|-----------------------------|
| description | <i>ip-address</i> | IP address of the next hop. |

**Default configuration** None

**Command mode** Route map configuration mode

You can redistribute the routing information from one routing process to another routing process. For example, you can redistribute the route in the OSPF routing domain and then advertise it to the RIP routing domain, and vice versa. The mutual route redistribution can be implemented between all the IP routing protocols.

**Usage guideline**

In the route redistribution, route maps are usually used to control the mutual route redistribution between two routing domains.

In configuring one route map, one or more match or set commands can be executed. If the match command is not used, all the routes will be matched. If the set command is not used, no operation will be performed.

The following example enables the OSPF routing protocol to redistribute the RIP route and sets the next-hop to 192.168.1.2.

**Examples**

```
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# match ip address 1
Ruijie(config-route-map)# set next-hop 192.168.1.2
```

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |
| <b>match metric</b>          | Match the metric.              |
| <b>match route-type</b>      | Match the route type.          |
| <b>match tag</b>             | Match the tag.                 |
| <b>set metric-type</b>       | Set the metric type.           |
| <b>set tag</b>               | Set the tag.                   |

**Related commands**

## 10.56 set origin

Use this command to set the source of the routes to be redistributed in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set origin {egp | igp | incomplete}**

**no set origin**

| Parameter  | Description                                     |
|------------|-------------------------------------------------|
| egp        | Redistribute the routes from the remote EGP.    |
| igp        | Redistribute the routes from the local IGP.     |
| incomplete | Redistribute the routes from an unknown device. |

**Default configuration** None

**Command mode** Route map configuration mode

**Usage guideline** Use this command to set the source of the routes to be matched. Only one route source attribute can be set.

### Examples

```
Ruijie(config)# route-map SET_ORIGIN 10 permit
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set origin igp
Ruijie(config-route-map)# exit
Ruijie(config)# route-map SET_ORIGIN 20 permit
Ruijie(config-route-map)# match as-path 2
Ruijie(config-route-map)# set origin egp
```

### Related commands

| Command                     | Description                                     |
|-----------------------------|-------------------------------------------------|
| <b>match as-path</b>        | Match the AS_PATH attribute.                    |
| <b>match metric</b>         | Match the route metric.                         |
| <b>match origin</b>         | Match the source.                               |
| <b>set as-path prepend</b>  | Set the AS_PATH attribute.                      |
| <b>set metric</b>           | Set the metric.                                 |
| <b>set local-preference</b> | Set the local priority of redistributed routes. |

## 10.57 set originator-id

Use this command to set the source of the routes to be redistributed in the route map configuration mode. Use the **no** form of this command to remove the setting.

**set originator-id ip-address**

**no set originator-id** [*ip-address*]

| Parameter description | Parameter         | Description                   |
|-----------------------|-------------------|-------------------------------|
|                       | <i>ip-address</i> | IP address of the originator. |

**Default configuration** None

**Command mode** Route map configuration mode

**Usage guideline** Use this command to set the source of the routes to be matched.

**Examples**

```
Ruijie(config)# route-map SET_ORIGIN 10 permit
Ruijie(config-route-map)# match as-path 1
Ruijie(config-route-map)# set originator-id 5.5.5.5
Ruijie(config-route-map)# exit
Ruijie(config)# route-map SET_ORIGIN 20 permit
Ruijie(config-route-map)# match as-path 2
Ruijie(config-route-map)# set originator-id 5.5.5.6
```

**Related commands**

| Command                     | Description                                     |
|-----------------------------|-------------------------------------------------|
| <b>match as-path</b>        | Match the AS_PATH attribute.                    |
| <b>match metric</b>         | Match the route metric.                         |
| <b>match origin</b>         | Match the source.                               |
| <b>set as-path prepend</b>  | Set the AS_PATH attribute.                      |
| <b>set metric</b>           | Set the metric.                                 |
| <b>set local-preference</b> | Set the local priority of redistributed routes. |

## 10.58 set tag

Use this command to set the tag for the routes to be redistributed. Use the **no** form of this command to remove the setting.

**set tag** *tag*

**no set tag**

| Parameter description | Parameter  | Description                          |
|-----------------------|------------|--------------------------------------|
|                       | <i>tag</i> | Tag of the route to be redistributed |

**Default configuration** The original routing tag remains unchanged.

**Command****mode** Route map configuration mode**Usage guideline** This command can only be used for route redistribution. If this command is not configured, the default route tag is used.

The following example enables the OSPF routing protocol to redistribute the RIP route and sets the tag as 100.

**Examples**

```
Ruijie(config)# router ospf
Ruijie(config-router)# redistribute rip subnets route-map redrip
Ruijie(config-router)# network 192.168.12.0 0.0.0.255 area 0
Ruijie(config-router)# exit
Ruijie(config)# route-map redrip permit 10
Ruijie(config-route-map)# set tag 100
```

**Related commands**

| Command                      | Description                    |
|------------------------------|--------------------------------|
| <b>match interface</b>       | Match the interface.           |
| <b>match ip address</b>      | Match the IP address.          |
| <b>match ip next-hop</b>     | Match the next-hop IP address. |
| <b>match ip route-source</b> | Match the source IP address.   |
| <b>match metric</b>          | Match the metric.              |
| <b>match route-type</b>      | Match the route type.          |
| <b>match tag</b>             | Match the tag.                 |
| <b>set metric</b>            | Set the metric.                |
| <b>set metric-type</b>       | Set the metric type.           |

## 10.59 set weight

Use this command to set the weight for the BGP routes matching filtering rules. Use the **no** form of this command to remove the setting.

**set weight** *number***no set weight****Parameter description**

| Parameter     | Description                       |
|---------------|-----------------------------------|
| <i>number</i> | Weight in the range of 0 to 65535 |

**Default****configuration** None**Command** Route map configuration mode

**mode****Usage  
guideline**

This command can only be used modify the weight of a BGP route.

By default, the weight of the route learned from a neighbor is the one configured with the neighbor weight command. The weight of the locally generated route is fixed 32768.

The following example sets the weight for the BGP route learned from the neighbor 1.1.1.1 at the inbound direction to 100.

**Examples**

```
Ruijie(config)# router bgp 1
Ruijie(config-router)# neighbor 1.1.1.1 route-map nei-rmap-in in
Ruijie(config-router)# exit
Ruijie(config)# route-map nei-rmap-in permit 10
Ruijie(config-route-map)# set weight 100
```

**Related  
commands**

| Command                | Description                                     |
|------------------------|-------------------------------------------------|
| <b>match as-path</b>   | Match the AS_PATH attribute.                    |
| <b>match community</b> | Match the route community.                      |
| <b>match metric</b>    | Match the route metric.                         |
| <b>match origin</b>    | Match the source.                               |
| <b>set community</b>   | Set community of the redistributed route.       |
| <b>set metric</b>      | Set the metric of the redistributed route.      |
| <b>set metric type</b> | Set the metric type of the redistributed route. |

## 10.60 show ip as-path-access-list

Use this command to display the configuration of AS path access lists.

**show ip as-path-access-list [ num ]**

**Parameter  
description**

| Parameter  | Description                 |
|------------|-----------------------------|
| <i>num</i> | AS path access list number. |

**Default**

N/A

**Command  
mode**

Privileged EXEC mode

**Usage  
guideline**

N/A

**Examples**

The following example displays the AS path access lists.

```
Ruijie# show ip as-path-access-list
```

```
AS path access list 30
permit ^30$
```

| Field               | Description                                         |
|---------------------|-----------------------------------------------------|
| AS path access list | AS path access list number                          |
| permit              | Permits advertisement based on matching conditions. |
| ^30\$               | Regular expression.                                 |

### 10.61 show ip community-list

Use **show ip community-list** command to display the community list.

**show ip community-list** [*community-list-number* | *community-list-name*]

| Parameter description | Parameter                    | Description                   |
|-----------------------|------------------------------|-------------------------------|
|                       | <i>community-list-number</i> | Number of the community list. |
|                       | <i>community-list-name</i>   | Name of the community list.   |

Default configuration None

Command mode Privileged EXEC mode

Usage guidelines N/A

**Examples**

```
Ruijie# show ip community-list
Community-list standard local
permit local-AS
Community-list standard Red-Giant
permit 0:10
deny 0:20
```

| Related commands | Command              | Description                                       |
|------------------|----------------------|---------------------------------------------------|
|                  | match community      | Match the route community.                        |
|                  | set comm-list delete | Delete the community attribute in the BGP routes. |

## 10.62 show ip extcommunity-list

Use this command to display the extcommunity list.

**show ip extcommunity-list** [ *extcommunity-list-num* | *extcommunity-list-name* ]

| Parameter   | Parameter                     | Description                                      |
|-------------|-------------------------------|--------------------------------------------------|
| description | <i>extcommunity-list-num</i>  | extcommunity-list number, ranging from 1 to 199. |
|             | <i>extcommunity-list-name</i> | extcommunity-list name.                          |

**Default** -

**Command mode** Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode and route map configuration mode.

**Usage guideline** -

**Examples**

```
Ruijie # show ip extcommunity-list
Standard extended community-list 1
 10 permit RT:1:200
 20 permit RT:1:100
Standard extended community-list 2
 10 permit RT:1:200
Expanded extended community-list rt_filter
 13 permit 1:100
```

| Related command | Command                     | Description                  |
|-----------------|-----------------------------|------------------------------|
|                 | <b>ip extcommunity-list</b> | Create an extcommunity-list. |
|                 | <b>match extcommunity</b>   | Match an extcommunity.       |
|                 | <b>set extcommunity</b>     | Set an extcommunity.         |

**Platform description** -

## 10.63 show ip prefix-list

Use **show ip prefix-list** to display the prefix list or the entries.

**show ip prefix-list** [*prefix-name*]

| Parameter   | Parameter          | Description              |
|-------------|--------------------|--------------------------|
| description | <i>prefix-name</i> | Name of the prefix list. |

**Default**

**configuration** The configuration information of all the prefix lists is displayed by default.

**Command mode**

Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode, route map configuration mode.

**Usage guidelines**

If no prefix list is specified, the configurations of all the prefix lists are displayed, otherwise only the configuration of the specified prefix list is displayed.

**Examples**

```
Ruijie# show ip prefix-list
seq pre: 2 entries
seq 5 permit 192.168.564.0/24
seq 10 permit 192.2.2.0/24
```

## 10.64 show ip protocols

Use this command to display information about the status of the currently running IPv4 routing protocol.

**show ip protocols** [ *vrf vrf-name* ] { **bgp** | **isis** | **ospf** | **rip** }

**Parameter Description**

| Parameter       | Description                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | Specifies the VRF instance name. If it is not specified, information about the status of routing protocols in global VRF mode is displayed. |
| <b>bgp</b>      | Displays information about the status of the BGP protocol.                                                                                  |
| <b>isis</b>     | Displays information about the status of the IS-IS protocol.                                                                                |
| <b>ospf</b>     | Displays information about the status of the OSPF protocol.                                                                                 |
| <b>rip</b>      | Displays information about the status of the RIP protocol.                                                                                  |
| -               | Displays information about the status of all running routing protocols.                                                                     |

**Command Mode**

Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode, and routing map configuration mode

**Default Level** 14

**Usage Guide**

Information about the status of only the currently running routing protocol is displayed, and the information about a routing protocol that is not running is not displayed.

**Examples**

The following example displays the status of routing protocols running in global VRF mode.

```
Ruijie# show ip protocols
Routing Protocol is "ospf 1"
  Outgoing update filter list for all interfaces is not set
  Incoming update filter list for all interfaces is not set

| Distance:                           | Distance information of a routing protocol        |

## 10.65 show ipv6 prefix-list

Use this command to display the information about the IPv6 prefix list or its entries.

**show ipv6 prefix-list** [*prefix-name*]

| Parameter description | Parameter          | Description                   |
|-----------------------|--------------------|-------------------------------|
|                       | <i>prefix-name</i> | Name of the IPv6 prefix list. |

**Default**

**configuration** The configuration information of all the IPv6 prefix lists is displayed.

**Command mode**

Privileged EXEC mode, global configuration mode, interface configuration mode, route protocol configuration mode, route map configuration mode

**Usage guideline**

If no prefix list is specified, the configurations of all the prefix lists are displayed, otherwise only the configuration of the specified prefix list is displayed.

**Examples**

```
Ruijie# show ipv6 prefix-list
ipv6 prefix-list p6: 2 entries
    seq 5 permit 13::/20
    seq 10 permit 14::/20
```

## 10.66 show key chain

Use this command to display the key chain configuration.

**show key chain** [*key-chain-name*]

**Parameter description**

| Parameter             | Description                                                      |
|-----------------------|------------------------------------------------------------------|
| <i>key-chain-name</i> | (Optional) Display the configuration of the specified key chain. |

**Default**

The configuration information of all key chains is displayed.

**Command mode**

Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode, and key chain configuration mode.

**Usage guideline**

If no key chain is specified, the configuration information of all key chains is displayed.

**Examples**

```
Ruijie# show key chain
route-map AAA, permit, sequence 10
Match clauses:
ip address 2
Set clauses:
metric 10
Ruijie(config)#show key chain
key chain kc
    key 1 -- text "ruijie"
        accept-lifetime (12:11:00 May 2 2001) - (infinite)
        send-lifetime (always valid) - (always valid) [valid now]
```

| Field           | Description                       |
|-----------------|-----------------------------------|
| key chain       | Key chain name.                   |
| key             | Key ID.                           |
| accept-lifetime | Lifetime in the accept direction. |
| send-lifetime   | Lifetime in the send direction.   |

| Related command | Command | Description |
|-----------------|---------|-------------|
|                 | -       | -           |

**Platform description** -

## 10.67 show route-map

Use the command to display the configuration of the route map.

**show route-map** [*route-map-name*]

| Parameter description | Parameter             | Description                                                                      |
|-----------------------|-----------------------|----------------------------------------------------------------------------------|
|                       | <i>route-map-name</i> | (Optional) Display the configuration information of the specified the route map. |

**Default configuration** The configuration information of all the route maps is displayed.

**Command mode** Privileged EXEC mode, global configuration mode, interface configuration mode, routing protocol configuration mode, route map configuration mode.

**Usage guidelines** If no route map is specified, the configurations of all the route maps will be displayed, otherwise only the configuration of the specified route map is displayed.

**Examples**

```
Ruijie# show route-map
route-map AAA, permit, sequence 10
Match clauses:
ip address 2
Set clauses:
metric 10
```

| Field     | Description                                |
|-----------|--------------------------------------------|
| route-map | Name of the route map.                     |
| Permit    | The route map contains the permit keyword. |

---

|               |                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------|
| sequence 10   | Sequence number of the route map.                                                                                   |
| Match clauses | Set the matching rule. Whether to perform the set operation depends on the permit or deny keyword in the route map. |
| Set clauses   | Set the operation when the rule is matched.                                                                         |

# 1 IPv4 Multicast Routing Configuration Commands

## 1.1 clear ip mroute

Use this command to remove the forwarding information of the IP multicast routes.

**clear ip mroute** { \* | *group-address* [*source -address*] }

| Parameter             | Description                                                            |
|-----------------------|------------------------------------------------------------------------|
| *                     | Remove all the forwarding information in the IP multicast route table. |
| <i>group-address</i>  | Group IP address of IP multicast routes.                               |
| <i>source-address</i> | Source IP address of multicast routess.                                |

**Command Mode** Privileged EXEC mode.

**Examples** The following example removes the entry whose group IP address is 230.0.0.1 from the multicast routing table:

```
Ruijie# clear ip mroute 230.0.0.1
```

| Command        | Description                                          |
|----------------|------------------------------------------------------|
| show ip mroute | Show the forwarding information of multicast routes. |

## 1.2 clear ip mroute statistics

Use this command to remove the statistics of IP multicast routes.

**clear ip mroute statistics** { \* | *group-address* [*source -address*] }

| Parameter             | Description                                                     |
|-----------------------|-----------------------------------------------------------------|
| *                     | Remove all the forwarding entries in the multicast route table. |
| <i>group-address</i>  | Group IP address of IP multicast routes                         |
| <i>source-address</i> | Source IP address of multicast route.                           |

**Command Mode** Privileged EXEC mode.

**Usage Guide**

**Examples**

The following example clears the statistics of entry with the group IP address 230.0.0.1 from the multicast routing table.

```
Ruijie# clear ip mroute statistics 230.0.0.1
```

**Related Commands**

| Command         | Description                                       |
|-----------------|---------------------------------------------------|
| show ip mroute  | Show the multicast route forwarding information.  |
| clear ip mroute | Clear the multicast route forwarding information. |

## 1.3 ip mroute

Use this command to configure static multicast routes. Use the **no** or **default** form of this command to delete the configured routes.

**ip mroute** *source-address mask* { [*protocol*] { [*rpf-address*] | *interface-type interface-number* } } [*distance*]

**no ip mroute** *source-address mask* [*protocol*]

**default ip mroute** *source-address mask* [ *protocol* ]

**Parameter Description**

| Parameter                                        | Description                                                                                                                    |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>source-address</i>                            | Source IP address of the multicast route                                                                                       |
| <i>mask</i>                                      | Mask of the source IP address                                                                                                  |
| <i>protocol</i>                                  | (Optional) The unicast routing protocol being used.                                                                            |
| <i>rpf-address</i>                               | Incoming interface of the multicast route                                                                                      |
| <i>interface-type</i><br><i>interface-number</i> | Interface type and interface ID.                                                                                               |
| <i>distance</i>                                  | Management distance used to determine whether to use the route for RPF routing, ranging from 1 to 255. The default value is 0. |

**Default**

*distance*: 0.

**Command Mode**

Global configuration mode.

**Usage Guide**

This command is used to configure the route for the purpose of RFF check. Note that the configured route is prior to the route learned in the unicast form.

**Examples**

The following example allows the multicast routes of all the sources in a network to pass 172.30.10.13:

```
Ruijie(config)# ip mroute 172.16.0.0 255.255.0.0
172.30.10.13
```

## 1.4 ip multicast-routing

Use this command to enable multicast routing forwarding. The **no** form of this command disables multicast routing forwarding.

**ip multicast-routing** [*vrf vrf-name*]

**no ip multicast-routing** [*vrf vrf-name*]

| Parameter   | Parameter    | Description               |
|-------------|--------------|---------------------------|
| Description | vrf vrf-name | Specify the VRF instance. |

**Default** Disabled.

**Command Mode** Global configuration mode.

This command allows you to enable IPv4 multicast routing forwarding. The multicast protocol will not be enabled with IPv4 multicast routing forwarding disabled.

### Usage Guide

 It is not recommended to configure different v4 multicast routing protocols on different interfaces of a device.

### Examples

This command enables multicast routing forwarding.

```
Ruijie(config)# ip multicast-routing
```

## 1.5 ip multicast boundary

Use this command to configure the boundary of an IP multicast group. Use the **no** or **default** form of this command to remove the configured boundary.

**ip multicast boundary** *access-list* [ **in** | **out** ]

**no ip multicast boundary** *access-list* [ **in** | **out** ]

**default ip multicast boundary** *access-list* [ **in** | **out** ]

| Parameter   | Parameter          | Description                                         |
|-------------|--------------------|-----------------------------------------------------|
| Description | <i>access-list</i> | Access list associated with the multicast boundary. |
|             | <b>in</b>          | Inbound direction.                                  |
|             | <b>out</b>         | Outbound direction.                                 |

**Default** The boundary of a specified IP multicast group is defined by default.

**Command Mode** Interface configuration mode

Note that the ACL associated with the multicast boundary is either standard ACL or extended ACL. But the extended ACL only match the destination IP address.

### Usage Guide

Note:

This command filters IGMP and PIMSM packets of the specified IP address range. Multicast packets will not be received and sent through the interface of the boundary.

The following example configures svi1 as the boundary of all IP multicast groups.

### Examples

```
Ruijie(config)# ip access-list mul-boun
Ruijie(config-std-nacl)# permit ip 233.3.3.0 0.0.0.255
Ruijie(config-std-nacl)#exit
Ruijie(config)# interface vlan 1
Ruijie(config-if)# ip multicast boundary mul-boun
```

## 1.6 ip multicast route-limit

Use this command to limit the number of the entries that can be added to the multicast routing table. Use the **no** or **default** form of this command to remove the configuration.

**ip multicast route-limit** *limit* [*threshold*]

**no ip multicast route-limit** *limit*

**default ip multicast route-limit**

### Parameter

### Description

| Parameter        | Description                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>limit</i>     | The number of the entries that can be added to the multicast routing table is 1 to 2147483647. The default value is 1024. |
| <i>threshold</i> | (Optional) Number of multicast routes at which alarms will be triggered. The default value is 2147483647.                 |

### Default

The default value of *limit* is 1024.

The default value of *threshold* is 2147483647.

### Command Mode

Global configuration mode.

### Usage Guide

Note that the hardware resources of different devices are limited. The routes exceeding the hardware resource will be forwarded by software, which leads to lower product performance.

### Examples

The following example sets the route limit to 500.

```
Ruijie(config)# ip multicast route-limit 500
```

## 1.7 ip multicast rpf longest-match

Select the multicast static routing, MBGP routing and unicast routing that could be used for the RPF check from the multicast static routing table, MBGP routing table and unicast routing table respectively by following the RPF rules.

Use this command to select the one with the mask longest-matched from the three routings. If the routings are in the same priority, select the routing in order of multicast static routing, MBGP routing, unicast routing.

Use the **no** or **default** form of this command restores it to the default setting. By default, select one routing of the highest priority from the three routings. If the routings are in the same priority, select the routing in order of multicast static routing, MBGP routing, unicast routing.

**ip multicast rpf longest-match**

**no ip multicast rpf longest-match**

**default ip multicast rpf longest-match**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

### Default

Use the RPF rule to select the optimal routing for RPF check from the multicast static routing, MBGP routing and unicast routing that are used for the RPF check from the multicast static routing table, MBGP routing table and unicast routing table respectively by following the RPF rules. Then select one routing of the highest priority from the three routings. If the routings are in the same priority, select the routing in order of multicast static routing, MBGP routing, unicast routing.

### Command Mode

Global configuration mode.

### Examples

The following example configures to select the routing with the longest-match.

```
Ruijie(config)# ip multicast rpf longest-match
```

## 1.8 ip multicast static

Use this command to enable flow control for multicast packets on the Layer 2 interface. Use the **no** or **default** form of this command removes the setting.

**ip multicast static** *source-address group-address interface-type interface-number*

**no ip multicast static** *source-address group-address interface-type interface-number*

**default ip multicast static** *source-address group-address interface-type interface-number*

| Parameter   | Parameter             | Description                       |
|-------------|-----------------------|-----------------------------------|
| Description | <i>source-address</i> | Source IP address                 |
|             | <i>group-address</i>  | IP address of the multicast group |

|                                        |                                                                     |
|----------------------------------------|---------------------------------------------------------------------|
| <i>interface-type interface number</i> | Layer 2 interface on which multicast packets are allowed to forward |
|----------------------------------------|---------------------------------------------------------------------|

**Default** This function is disabled by default.

**Command Mode** Global configuration mode

You can configure more than one command (or more than one interface) for a multicast flow. With flow control enabled, the multicast flow can only be forwarded through these configured interfaces.

**Usage Guide** This command controls the forwarding of multicast flows on an interface without any direct influence on the packet processing of multicast protocols. However, the action of a multicast protocol (for instance, PIM-DM or PIM-SM) may be affected because some features of the multicast protocol are driven by multicast flows.

The following example configures forwarding multicast flows (192.168.43.4 and 255.1.1.5) through GigabitEthernet 2/6 and FastEthernet 3/2.

**Examples**

```
Ruijie(config)# ip multicast static 192.168.43.4 255.1.1.5 G2/6
Ruijie(config)# ip multicast static 192.168.43.4 255.1.1.5 F3/2
```

## 1.9 ip multicast ttl-threshold

Use this command to configure TTL (time-to-live) threshold on the interface. Use the **no** or **default** form of the command to restore it to the default value.

**ip multicast ttl-threshold** *ttl-value*

**ip multicast ttl-threshold**

**default ip multicast ttl-threshold**

| Parameter   | Parameter        | Description                                                   |
|-------------|------------------|---------------------------------------------------------------|
| Description | <i>ttl-value</i> | TTL threshold on the interface, within the range of 0 to 255. |

**Default** The default *ttl-value* is 0.

**Command Mode** Interface configuration mode.

**Usage Guide** Use show running-config to display configuration. A device with multicast enabled can maintain one TTL threshold for every interface. If the TTL of the multicast packet received is greater than the threshold of the interface, the packets will be forwarded. Otherwise, the packet is discarded. Note that the TTL threshold is effective only to the multicast frames. In addition, you must configure it on the L3 interface.

**Examples**

The following example sets the TTL threshold on the interface to 5.

```
Ruijie(config-if)# ip multicast ttl-threshold 5
```

### 1.10 msf force-forwarding

Use this command to enable IPv4 multicast data packets destined for the CPU to be forcedly forwarded by software. Use the **no** or **default** form of this command to restore the default settings.

- msf force-forwarding**
- no msf force-forwarding**
- default msf force-forwarding**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Command Mode** Global configuration mode

**Defaults** This function is disabled by default.

**Usage Guide** N/A

**Examples**

The following example enable IPv4 multicast data packets destined for the CPU to be forcedly forwarded by software.

```
Ruijie(config)# msf force-forwarding
```

### 1.11 msf ipmc-overflow override

Use this command to enable the overflow overriding mechanism. Use the **no** or **default** form of this command to remove the configuration.

- msf ipmc-overflow override**
- no msf ipmc-overflow override**
- default msf ipmc-overflow override**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | -         | -           |

**Default** This function is disabled by default.

**Command Mode** Global configuration mode.

**Usage Guide** N/A

**Examples**

The following example enables the overflow overriding mechanism.

```
Ruijie (config)# msf ipmc-overflow override
Ruijie (config)#
```

## 1.12 msf nsf

Use this command to configure the parameter for the continuous multicast forwarding. Use the **no** or **default** form of this command to remove the configuration.

**msf nsf** **{convergence-time** *time* **|** **{leak** *interval* **}**

**no msf nsf** **{convergence-time | leak}**

**default msf nsf** **{convergence-time | leak}**

**Parameter**  
**Description**

| Parameter                                | Description                                                                             |
|------------------------------------------|-----------------------------------------------------------------------------------------|
| <b>convergence-time</b> <i>ttl-value</i> | Maximum time for the multicast protocol convergence, in the valid range of the 0-3600s. |
| <b>leak</b> <i>interval</i>              | Packet multicast leak time, in the valid range of 0-3600s                               |

**Default**

convergence-time *time* :140s;  
leak interval: 150s

**Command Mode**

Global configuration mode.

**Usage Guide**

N/A

**Examples**

The following example sets the maximum time for the protocol convergence.

```
Ruijie (config)# msf nsf convergence-time 300
Ruijie (config)#
```

The following example sets the packets leak time:

```
Ruijie(config)# msf nsf leak 200
Ruijie(config)#
```

## 1.13 show ip mrf mfc

Use this command to show the IPv4 multicast routing forwarding table.

**show ip mrf mfc** [*source-address group-address*]

**Parameter**  
**Description**

| Parameter             | Description                                                 |
|-----------------------|-------------------------------------------------------------|
| <i>source-address</i> | Source address of the multicast routing forwarding entries. |
| <i>group-address</i>  | Group address of the multicast routing forwarding entries.  |

**Default**

-

**Command Mode**

Privileged EXEC mode/Global configuration mode/Interface configuration mode

The three parameters in this command are optional, wherein the source address and group address must be specified at the same time.

**Usage Guide**

- If no source address and group address are specified, all mfc entries are displayed.
- When the source address and group address are specified only, the entries corresponding to the source and group addresses are displayed.

The following example shows all IPv4 layer-3 multicast routing forwarding entries with source address 20.0.1.30.

```
Ruijie#show ip mrf mfc 20.0.1.30 233.3.3.3
Multicast Routing and Forwarding Cache Table
(20.0.1.30, 233.3.3.3)
FAST_SW, SWTCHED, MIN_MTU: 1500, MIN_MTU_IFINDEX: 4099, WRONG IF: 0
Incoming interface: VLAN 1[4097]
Outgoing interface list:
VLAN 3 (1)
```

The fields in the execution of the **show ip mrf mfc** command are described in the following table.

**Examples**

| Field              | Description                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20.0.1.30          | Source address of the entry.                                                                                                                                    |
| 233.3.3.3          | Group address of the entry.                                                                                                                                     |
| FAST_SW            | The Flag shows whether to allow the fast forwarding or not. If the non-Ethernet interface, ppp, hdlc and frame relay exist, no fast forwarding entry generates. |
| SWTCHED            | Indicate whether the entry configuration on the next layer forwarding table has done not not.                                                                   |
| MIN_MTU MTU        | The minimum MTU of the entry.                                                                                                                                   |
| MIN_MTU_IFINDEX    | The interface index with the minimum MTU value.                                                                                                                 |
| WRONG IF           | The statistics number of the multicast data packets received on the wrong incoming interface.                                                                   |
| Incoming interface | Incoming interface of the entry.                                                                                                                                |
| VLAN 3 (1)         | The layer-3 outgoing interface of the entry is VLAN3. 1 for the ttl threshold of this layer-3 interface.                                                        |

## 1.14 show ip mroute

Use this command to show the multicast forwarding table.

**show ip mroute** [*group-or-source-address* [ *group-or-source-address* ]] [**dense** | **sparse** ]  
[**summary** | **count** ]

### Parameter Description

| Parameter                      | Description                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>group-or-source-address</i> | Multicast or source IP address                                                                                              |
| <i>group-or-source-address</i> | Multicast or source IP address. The two addresses must not be the multicast addresses or source addresses at the same time. |
| <b>dense</b>                   | Show PIM-DM multicast routing table.                                                                                        |
| <b>sparse</b>                  | Show PIM-SM multicast routing table.                                                                                        |
| <b>summary</b>                 | Show the summary of the multicast routing table.                                                                            |
| <b>count</b>                   | Show the count of the multicast routing table.                                                                              |

### Command Mode

Privileged EXEC mode/Global configuration mode/Interface configuration mode

The three parameters in this command are optional, wherein the source address and group address must be specified at the same time.

### Usage Guide

- If no source address and group address are specified, all mfc entries are displayed.
- When the source address and group address are specified only, the mfc entries corresponding to the source and group addresses are displayed.

The following example shows the information of the multicast routing table:

```
Ruijie# show ip mroute
IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(10.10.1.52, 224.0.1.3), uptime 00:00:31, stat expires 00:02:59
Owner PIM-SM, Flags: TF
Incoming interface: FastEthernet 2/1
Outgoing interface list:
FastEthernet 1/3
```

### Examples

The following example shows the information of a specific entry:

```
Ruijie# show ip mroute 10.10.1.52 224.0.1.3
IP Multicast Routing Table
```

```

Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(10.10.1.52, 224.0.1.3), uptime 00:03:24, stat expires 00:01:28
Owner PIM-SM, Flags: TF
Incoming interface: FastEthernet 2/1
Outgoing interface list:
FastEthernet 1/3

```

The following example shows the count of the routing table:

```

Ruijie# show ip mroute count
IP Multicast Statistics
Total 1 routes using 132 bytes memory
Route limit/Route threshold: 2147483647/2147483647
Total NOCACHE/WRONGVIF/WHOLEPKT rcv from fwd: 1/0/0
Total NOCACHE/WRONGVIF/WHOLEPKT sent to clients: 1/0/0
Immediate/Timed stat updates sent to clients: 0/0
Reg ACK rcv/Reg NACK rcv/Reg pkt sent: 0/0/0
Next stats poll: 00:01:10
Forwarding Counts: Pkt count/Byte count, Other Counts: Wrong If pkts
Fwd msg counts: WRONGVIF/WHOLEPKT rcv
Client msg counts: WRONGVIF/WHOLEPKT/Imm Stat/Timed Stat sent
Reg pkt counts: Reg ACK rcv/Reg NACK rcv/Reg pkt sent
(10.10.1.52, 224.0.1.3), Forwarding: 2/19456, Other: 0
Fwd msg: 0/0, Client msg: 0/0/0/0, Reg: 0/0/0

```

The following example shows the summary of the routing table:

```

Ruijie# show ip mroute summary
IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(10.10.1.52, 224.0.1.3), 00:01:32/00:03:20, PIM-SM, Flags: T

```

| Field                     | Description                                                                         |
|---------------------------|-------------------------------------------------------------------------------------|
| Flags                     | I-Immediate statistic<br>T-Timed statistic<br>F-Already set to the forwarding table |
| Timers:Uptime/Stat Expiry | Time when the entry is created.<br>Time when it is aged.                            |
| Interface State           | Interface state.                                                                    |
| Owner                     | Owner of the entry, which may be a multicast routing protocol                       |

|                                          |                                                                                                                        |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Incoming interface                       | Expected packet incoming interface. If the actual incoming interface does not match it, the packets will be discarded. |
| Outgoing interface list                  | Outgoing interface list; the packets will be forwarded on the interfaces in the list.                                  |
| Forwarding Counts: Pkt count/Byte count, | Forwarding count: packet count/byte count forwarded by the entry                                                       |
| Other Counts: Wrong If pkts              | Count of the packets received from the wrong incoming interface.                                                       |

## Related Commands

| Command                     | Description                                |
|-----------------------------|--------------------------------------------|
| <b>ip multicast-routing</b> | Enabling the multicast routing forwarding. |
| <b>ip pim dense-mode</b>    | Enable the PIM-DM on the interface.        |
| <b>ip pim sparse-mode</b>   | Enable the PIM-SM on the interface.        |

## 1.15 show ip mroute static

Use this command to show the v4 static multicast routing information.

**show ip mroute static**

## Parameter

## Description

| Parameter | Description |
|-----------|-------------|
| -         | -           |

## Command Mode

Privileged EXEC mode/Global configuration mode/Interface configuraion mode

## Usage Guide

In the same conditions, the priority of the static multicast routing is higher than the dynamically learned.

## Examples

The following example shows the information of the user-configured static multicast routing:

```
Ruijie#show ip mroute static
Mroute: 172.16.0.0, RPF neighbor: 172.30.10.13
Protocol: , distance: 0
```

## 1.16 show ip mvif

Use this command to show the basic information of the multicast interface.

**show ip mvif { interface-type interface-number }**

## Parameter

## Description

| Parameter                              | Description               |
|----------------------------------------|---------------------------|
| <i>interface-type interface-number</i> | Interface Type and number |

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuraion mode

The following example shows the basic information of the multicast interface of svil.

**Examples**

```
Ruijie#show ip mvif vlan 1
Interface Vif Owner TTL Local Remote Uptime
Idx Module Address Address
VLAN 1 1 PIM-DM 2 192.168.1.1 0.0.0.0 00:13:16
```

## 1.17 show ip rpf

Use this command to show the RPF information of the specified source IP address.

**show ip rpf** {*source-address*}

| Parameter   | Parameter             | Description                 |
|-------------|-----------------------|-----------------------------|
| Description | <i>source-address</i> | Specified source IP address |

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuraion mode

The three parameters in this command are optional, wherein the source address and group address must be specified at the same time.

**Usage Guide**

- If no source address and group address are specified, all mfc entries are displayed.
- When the source address and group address are specified only, the mfc entries corresponding to the source and group addresses are displayed.

The following example shows the information of the RPF to 192.168.1.54:

**Examples**

```
Ruijie# show ip rpf 192.168.1.54
RPF information for 192.168.1.54
RPF interface: VLAN 1
RPF neighbor: 0.0.0.0
RPF route: 192.168.1.0/24
RPF type: unicast (connected)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 0
Metric: 0
```

## 1.18 show msf msc

Use this command to show IPv4 multi-layer multicast forwarding table.

**show msf msc** [*source-address*] [*group-address*]

| Parameter   | Parameter             | Description                                                                |
|-------------|-----------------------|----------------------------------------------------------------------------|
| Description | <i>source-address</i> | Specified source IP address of the multi-layer multicast forwarding table. |

|                      |                                                                        |
|----------------------|------------------------------------------------------------------------|
| <i>group-address</i> | Specified group address of the multi-layer multicast forwarding table. |
|----------------------|------------------------------------------------------------------------|

**Default** -

**Command**

**Mode** Privileged EXEC mode/Global configuration mode/Interface configuraion mode

The three parameters in this command are optional.

- If only the source address is specified as s1, all msc entries with source address 1 are displayed.

**Usage Guide**

- If the source address is specified as s1 and the group address as g1, all corresponding msc entries are displayed.
- Each parameter shall be input in order. Only when the parameter in front has been configured, the following one could be set.

The following example shows the IPv4 layer-3 multicast forwarding entries with source IP address 192.168.195.25:

```
Ruijie# show msf msc 192.168.195.25
Multicast Switching Cache Table
(192.168.195.23, 233.3.3.3, 1), SYNC, MTU:0, 1 OIFs
VLAN 1(0): 1 OPORTs, REQ: DONE
OPORT 6, IGMP-SNP, REQ: DONE
```

The fields in the execution of the **show mrf mfc** command are described in the following table.

**Examples**

| Field          | Description                                                                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 192.168.195.23 | Source address of the entry.                                                                                                                                                                                              |
| 233.3.3.3      | Group address of the entry.                                                                                                                                                                                               |
| 1              | Vlan id where the incoming interface of the entry is.                                                                                                                                                                     |
| SYNC           | The entry has been synchronized to the hardware.                                                                                                                                                                          |
| MTU            | MTU value                                                                                                                                                                                                                 |
| OIFs           | Layer-3 outgoing interface number.                                                                                                                                                                                        |
| VLAN1(0)       | The vlan where the layer-3 outgoing interface oif is.                                                                                                                                                                     |
| 1 OPORTs       | The number of layer-2 port in the layer-3 outgoing oif.                                                                                                                                                                   |
| REQ: DONE      | This oif configuration on the hardware has done.                                                                                                                                                                          |
| OPORT 6        | The layer-2 port in the oif with index 6.                                                                                                                                                                                 |
| IGMP-SNP       | This port is created by the IGMP SNOOPING protocol. This value can also be the PIM-SNP, which means this port is created by the PIM SNOOPING protocol. And the ROUTER means this port is created by the layer-3 protocol. |
| REQ: DONE      | The port configuration on the hardware has done.                                                                                                                                                                          |

## 1.19 show msf nsf

Use this command to show the configuration of continuous multicast forwarding.

**show msf nsf**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | -         | -           |

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuraion mode

The following example shows the configuration of continuous multicast forwarding.

### Examples

```
Ruijie# show msf nsf
Multicast HA Parameters
-----+-----+
protocol convergence timeout 120 secs
flow leak interval 20 secs
Ruijie#
```

| Related Commands | Command | Description                            |
|------------------|---------|----------------------------------------|
|                  | msf nsf | Configure the multicast NSF parameter. |

## 2 IPv6 Multicast Routing Commands

### 2.1 clear ipv6 mroute

Use this command to remove the specific or all IPv6 multicast forwarding entries.

**clear ipv6 mroute** { \* | *v6group-address* [*v6source -address*]}

| Parameter               | Description                                                               |
|-------------------------|---------------------------------------------------------------------------|
| *                       | Removes all the forwarding information in the IPv6 multicast route table. |
| <i>v6group-address</i>  | Group IPv6 address of IPv6 multicast routes                               |
| <i>v6source-address</i> | Source IPv6 address of multicast routes                                   |

#### Parameter Description

#### Command Mode

Privileged EXEC mode

#### Configuration

The following example removes all the multicast routing entries.

#### Examples

```
Ruijie# clear ip mroute *
```

#### Related Commands

| Command                             | Description |
|-------------------------------------|-------------|
| <b>show ipv6 mroute</b>             | N/A         |
| <b>clear ipv6 mroute statistics</b> | N/A         |

### 2.2 clear ipv6 mroute statistics

Use this command to remove the statistics of IPv6 multicast routes.

**clear ipv6 mroute statistics** { \* | *v6group-address* [*v6source -address*]}

| Parameter               | Description                                                      |
|-------------------------|------------------------------------------------------------------|
| *                       | Removes all the forwarding entries in the multicast route table. |
| <i>v6group-address</i>  | Group IPv6 address of IPv6 multicast routes                      |
| <i>v6source-address</i> | Source IPv6 address of multicast route                           |

#### Parameter

#### Description

#### Command Mode

Privileged EXEC mode

#### Usage Guide

-

#### Configuration

The following example clears all the statistical information of the multicast routing entries.

#### Examples

```
Ruijie# clear ip mroute statistics *
```

| Related<br>Commands | Command                  | Description                                          |
|---------------------|--------------------------|------------------------------------------------------|
|                     | <b>show ipv6 mroute</b>  | Displays the multicast route forwarding information. |
|                     | <b>clear ipv6 mroute</b> | Clears the multicast route forwarding information.   |

## 2.3 ipv6 mroute

Use this command to configure static IPv6 multicast routes. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mroute** *ipv6-prefix/prefix-length* [ *protocol* ] { *v6rpf-address* | *interface-type interface-number* } [ *distance* ]

**no ipv6 mroute** *ipv6-prefix/prefix-length* [ *protocol* ]

**default ipv6 mroute** *ipv6-prefix/prefix-length* [ *protocol* ]

| Parameter<br>Description | Parameter                                        | Description                                                                                                                    |
|--------------------------|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>ipv6-prefix/prefix-length</i>                 | Source IPv6 address of the multicast route                                                                                     |
|                          | <i>mask</i>                                      | Mask of the source IPv6 address                                                                                                |
|                          | <i>protocol</i>                                  | (Optional) The unicast routing protocol being used                                                                             |
|                          | <i>v6rpf-address</i>                             | Incoming interface of the multicast route                                                                                      |
|                          | <i>interface-type</i><br><i>interface-number</i> | Interface type and interface ID                                                                                                |
|                          | <i>distance</i>                                  | Management distance used to determine whether to use the route for RPF routing, ranging from 1 to 255. The default value is 0. |

**Defaults** The static IPv6 multicast routing is not configured by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure the route for the purpose of RFF check. Note that the configured route is prior to the route learned in the unicast form.  
If the outgoing direction of static multicast route but not the next-hop IP shall be specified, the outgoing direction must be of the point-to-point type.

**Configuration Examples** The following example allows the static multicast route 2233::/64 to pass 3333::3333:

```
Ruijie(config)# ipv6 mroute 2233::/64 3333::3333
```

## 2.4 ipv6 multicast boundary

Use this command to configure the boundary of an IPv6 multicast group. Use the **no** form of this command to restore the default setting.

**ipv6 multicast boundary** *access-list-name* [ *in* | *out* ]

**no ipv6 multicast boundary** *access-list-name* [ *in* | *out* ]

| Parameter   | Parameter               | Description                                        |
|-------------|-------------------------|----------------------------------------------------|
| Description | <i>access-list-name</i> | Access list associated with the multicast boundary |
|             | <b>in</b>               | Inbound redirection                                |
|             | <b>out</b>              | Outbound direction                                 |

**Defaults** The boundary of a specified IPv6 multicast group is not defined by default.

**Command Mode** Interface configuration mode

Note that the ACL associated with the multicast boundary is either standard ACL or extended ACL. But the extended ACL only match the destination IPv6 address.

#### Usage Guide

 This command filters MLD, PIM-SMv6 packets of the specified IPv6 address range. Multicast packets will not be received and sent through the interface of the boundary.

The following example configures svi1 as the boundary of all IPv6 multicast groups.

#### Configuration

#### Examples

```
Ruijie(config)# ip access-list mul-boun
Ruijie(config-std-nacl)# permit ip 233.3.3.0 0.0.0.255
Ruijie(config-std-nacl)#exit
Ruijie(config)# interface vlan 1
Ruijie(config-if)# ip multicast boundary mul-boun
```

## 2.5 ipv6 multicast route-limit

Use this command to limit the number of the entries that can be added to the IPv6 multicast routing table. Use the **no** or **global** form of this command to restore the default setting.

**ipv6 multicast route-limit** *limit* [*threshold*]

**no ipv6 multicast route-limit** *limit* [*threshold*]

**default ipv6 multicast route-limit** *limit* [ *threshold* ]

| Parameter   | Parameter        | Description                                                                                        |
|-------------|------------------|----------------------------------------------------------------------------------------------------|
| Description | <i>limit</i>     | The number of the entries that can be added to the IPv6 multicast routing table is 1 to 2147483647 |
|             | <i>threshold</i> | (Optional) Number of IPv6 multicast routes at which alarms will be triggered                       |

#### Defaults

The default value of *limit* is 1024.

The default value of *threshold* is 2147483647.

**Command Mode** Global configuration mode

**Usage Guide** The hardware resources of different devices are limited. The routes exceeding the hardware resource will be forwarded by software, which leads to lower product performance.

**Configuration** The following example sets the route limit to 500 and the warning value 90.

**Examples**

```
Ruijie(config)# ipv6 multicast route-limit 500 90
```

## 2.6 ipv6 multicast rpf longest-match

Use the RPF rule to select the static multicast route, MBGP route and the unicast route for the purpose of RPF check from the static multicast route list, the MBGP route list and the unicast route list.

Use this command to select one route with the longest-matched mask from the above-mentioned three routes. If the priority values of all three routes are the same, the routes will be selected in order of static multicast route, MBGP route and unicast route.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 multicast rpf longest-match**

**no ipv6 multicast rpf longest-match**

**default ipv6 multicast rpf longest-match**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

Use the RPF rule to select the static multicast route, MBGP route and the unicast route for the purpose of RPF check from the static multicast route list, the MBGP route list and the unicast route list.

**Defaults** Use this command to select one route, which is prior to the other two routes, with the longest-matched mask from the above-mentioned three routes. If the priority values of all three routes are the same, the routes will be selected in order of static multicast route, MBGP route and unicast route.

### Command

**Mode** Global configuration mode

### Usage

**Guide** N/A

**Configuration** The following example selects one route with the longest-matched mask from the above-mentioned three routes.

**Examples**

```
Ruijie(config)# ipv6 multicast rpf longest-match
```

## 2.7 ipv6 multicast static

Use this command to enable flow control for multicast packets on the Layer 2 interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 multicast static** *source-address group-address interface-type interface-number*

**no ipv6 multicast static** *source-address group-address interface-type interface-number*

**default ipv6 multicast static** *source-address group-address interface-type interface-number*

**Parameter Description**

| Parameter                              | Description                                                         |
|----------------------------------------|---------------------------------------------------------------------|
| <i>source-address</i>                  | Source IPv6 address                                                 |
| <i>group-address</i>                   | IPv6 address of the multicast group                                 |
| <i>interface-type interface number</i> | 2-layer interface on which multicast packets are allowed to forward |

**Defaults** This function is disabled by default.

**Command**

**Mode** Global configuration mode

You can configure more than one command (or more than one interface) for a multicast flow. With flow control enabled, the multicast flow can only be forwarded through these configured interfaces.

**Usage Guide**

This command controls the forwarding of multicast flows on an interface without any direct influence on the packet processing of multicast protocols. However, the action of a multicast protocol (for instance, PIM-SMv6) may be affected because some features of the multicast protocol are driven by multicast flows.

**Configuration**

The following example configures forwarding multicast flows (2222::3333, ff66::100) through GigabitEthernet 2/6 and FastEthernet 3/2.

**Examples**

```
Ruijie(config)# ipv6 multicast static 2222::3333 ff66::100 G2/6
Ruijie(config)# ipv6 multicast static 2222::3333 ff66::100 F3/2
```

## 2.8 ipv6 multicast-routing

Use this command to enable the IPv6 multicast routing forwarding. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 multicast-routing**

**no ipv6 multicast-routing**

**default ipv6 multicast-routing**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default

**Command Mode** Global configuration mode

Use this command to enable the IPv6 multicast routing forwarding. With this function disabled, the multicast protocol cannot be enabled.

#### Usage Guide

This command must be configured to enable the IPv6 multicast routing forwarding. This function conflicts with IGMP Snooping.

The following example enables the IPv6 multicast routing forwarding.

#### Configuration

```
Ruijie(config)# ipv6 multicast-routing
```

#### Examples

The following example disables the IPv6 multicast routing forwarding.

```
Ruijie(config)#no ipv6 multicast-routing
```

## 2.9 msf6 force-forwarding

Use this command to enable IPv6 multicast data packets destined for the CPU to be forcedly forwarded by software. Use the **no** or **default** form of this command to restore the default settings.

**msf6 force-forwarding**

**no msf6 force-forwarding**

**default msf6 force-forwarding**

#### Parameter

#### Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

#### Examples

The following example enable IPv6 multicast data packets destined for the CPU to be forcedly forwarded by software.

```
Ruijie(config)# msf6 force-forwarding
```

## 2.10 msf6 nsf

Use this command to configure parameters for multicast non-stop forwarding. Use the **no** or **default** form of this command to restore the default setting.

**msf6 nsf** { **convergence-time** *time* | **leak** *interval* }

**no msf6 nsf** { **convergence-time** | **leak** }

**default msf6 nsf** {**convergence-time** | **leak**}

| Parameter   | Parameter                              | Description                                                                                                                            |
|-------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Description | <b>convergence-time</b><br><i>time</i> | Maximum duration for which the system waits for multicast protocol convergence<br>The unit is second. The value ranges from 0 to 3600. |
|             | <b>leak</b> <i>interval</i>            | Interval at which multicast packets are leaked<br>The unit is second. The value ranges from 0 to 3600.                                 |

**Defaults** The default convergence-time is 20 seconds and leak interval is 30 seconds.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the maximum duration for which the system waits for multicast protocol convergence.

```
Ruijie (config)# msf6 nsf convergence-time 300
```

The following example sets the interval at which multicast packets are leaked.

```
Ruijie(config)# msf6 nsf leak 200
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 2.11 show ipv6 mrf6 mfc

Use this command to display the IPv6 multicast forwarding table.

**show ipv6 mrf6 mfc** [ *v6source-address v6group-address* ]

| Parameter   | Parameter              | Description                       |
|-------------|------------------------|-----------------------------------|
| Description | <i>v6group-address</i> | IPv6 address of a multicast group |

|                         |                                    |
|-------------------------|------------------------------------|
| <i>v6source-address</i> | IPv6 address of a multicast source |
|-------------------------|------------------------------------|

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** The two parameters are optional. The source address and group address must be specified together. If the two parameters are not specified, all mrf table entries will be displayed. If the two parameters are specified, the mrf entries of the specified source address and group address are displayed.

**Configuration Examples** The following example displays the 3-layer multicast forwarding table entries of IPv6 (the source address is 2000::1 and the group address is FF55::1).

```
Ruijie#show ipv6 mrf6 mfc 2000::1 FF55::1
Multicast Routing and Forwarding Cache6 Table
(2000::1, FF55::1)
FAST_SW, SWITCHED, MIN_MTU: 1500, MIN_MTU_IFINDEX: 4099, WRONG IF: 0
Incoming interface: VLAN 1[4097]
Outgoing interface list:
VLAN 3 (1)
```

| Field           | Description                                                                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000::1         | Source address of entries                                                                                                                                                                                                                                                                              |
| FF55::1         | Group address of entries                                                                                                                                                                                                                                                                               |
| FAST_SW         | Indicates whether the entries allow fast forwarding, that is, whether the entries can be forwarded by using hardware or software forwarding. If the entries include an interface that does not support the multicast function (for example, the GRE tunnel interface), fast forwarding is not allowed. |
| SWITCHED        | Indicates whether the entries have been placed in the forwarding table on the next layer.                                                                                                                                                                                                              |
| MIN_MTU MTU     | Minimum MTU value of entries                                                                                                                                                                                                                                                                           |
| MIN_MTU_IFINDEX | Index of the interface that has the minimum MTU value                                                                                                                                                                                                                                                  |
| WRONG IF        | Number of multicast packets sent from the wrong inbound interface                                                                                                                                                                                                                                      |
| VLAN 1[4097]    | Indicates that the rpf inbound interface is VLAN1. 4097 indicates the IFINDEX of the interface.                                                                                                                                                                                                        |
| VLAN 3 (1)      | Indicates that the 3-layer outbound interface of the entries is VLAN 3. 1 indicates the ttl threshold of the 3-layer interface.                                                                                                                                                                        |

## 2.12 show ipv6 mroute

Use this command to display the IPv6 multicast forwarding table.

**show ipv6 mroute** [*group-or-source-address* [ *group-or-source-address* ]] [**sparse**] [**summary** | **count**]

|                                        | Parameter                      | Description                                             |
|----------------------------------------|--------------------------------|---------------------------------------------------------|
| <b>Parameter</b><br><b>Description</b> | <i>group-or-source-address</i> | Multicat group IPv6 address                             |
|                                        | <i>group-or-source-address</i> | Multicast source IPv6 address                           |
|                                        | <b>sparse</b>                  | Displays the core entry of the multicast routing table. |
|                                        | <b>summary</b>                 | Displays the summary of the multicast routing table.    |
|                                        | <b>count</b>                   | Displays the count of the multicast routing table.      |

**Command**

**Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

The following example displays all information of the IPv6 multicast routing table.

```
Ruijie# show ipv6 mroute
IPv6 Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(2222::1234, ff56::1234), uptime 00:00:31, stat expires 00:02:59
Owner PIM-SMv6, Flags: TF
Incoming interface: FastEthernet 2/1
Outgoing interface list:
FastEthernet 1/3
```

The following example displays the count of the routing table.

```
Ruijie# show ipv6 mroute count
IPv6 Multicast Statistics
Total 1 routes using 168 bytes memory
Route limit/Route threshold: 1024/2147483647
Total NOCACHE/WRONGVIF/WHOLEPKT recv from fwd: 77/147/0
Total NOCACHE/WRONGVIF/WHOLEPKT sent to clients: 77/147/0
Immediate/Timed stat updates sent to clients: 0/29
Reg ACK recv/Reg NACK recv/Reg pkt sent: 0/0/0
Next stats poll: 00:00:09
Forwarding Counts: Pkt count/Byte count, Other Counts: Wrong If pkts
Fwd msg counts: WRONGVIF/WHOLEPKT recv
Client msg counts: WRONGVIF/WHOLEPKT/Imm Stat/Timed Stat sent
Reg pkt counts: Reg ACK recv/Reg NACK recv/Reg pkt sent
(2222::1234, ff56::1234), Forwarding: 1/0, Other: 0
Fwd msg: 0/0, Client msg: 0/0/0/0, Reg: 0/0/0
```

**Configurati  
on  
Examples**

The following example displays the summary of the routing table.

```
Ruijie# show ipv6 mroute summary
IPv6 Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL)
(2222::1234, ff56::1234), 00:00:28/00:03:25, PIM-SMv6, Flags: TF
```

| Field                     | Description                                                                         |
|---------------------------|-------------------------------------------------------------------------------------|
| Flags                     | I-Immediate statistic<br>T-Timed statistic<br>F-Already set to the forwarding table |
| Timers:Uptime/Stat Expiry | Time when the entry is created.<br>Time when it is aged.                            |
| Interface State           | Interface state.                                                                    |

|                                          |                                                                                                                        |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Owner                                    | Owner of the entry, which may be a multicast routing protocol                                                          |
| Incoming interface                       | Expected packet incoming interface. If the actual incoming interface does not match it, the packets will be discarded. |
| Outgoing interface list                  | Outgoing interface list; the packets will be forwarded on the interfaces in the list.                                  |
| Forwarding Counts: Pkt count/Byte count, | Forwarding count: packet count/byte count forwarded by the entry                                                       |
| Other Counts: Wrong If pkts              | Count of the packets received from the wrong incoming interface.                                                       |

## 2.13 show ipv6 mroute static

Use this command to display the static IPv6 multicast routing information.

**show ipv6 mroute static**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

### Command

**Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

### Usage

### Guide

The following example displays the static IPv6 multicast routing information.

**Configuration** Ruijie#show ipv6 mroute static

**Examples** Mroute: 2233::/64, RPF neighbor: 3333::3333  
Protocol: , distance: 0

## 2.14 show ipv6 mvif

Use this command to display the basic information of the multicast interface.

**show ipv6 mvif** { *interface-type interface-number* }

| Parameter   | Parameter                              | Description               |
|-------------|----------------------------------------|---------------------------|
| Description | <i>interface-type interface-number</i> | Interface type and number |

#### Command

**Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

The following example displays the basic information of the multicast interface of svil.

#### Configuration

```
Ruijie#show ipv6 mvif
Interface   Mif Owner   Uptime
           Idx Module
Register    0      03d03h09m
VLAN 1     1 PIMSMV6  03d03h09m
```

#### Examples

## 2.15 show ipv6 rpf

Use this command to display the RPF information of the specified source IPv6 address.

**show ipv6 rpf** *v6source-address*

| Parameter   | Parameter               | Description                   |
|-------------|-------------------------|-------------------------------|
| Description | <i>v6source-address</i> | Specified source IPv6 address |

#### Command

**Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

The following example displays the information of the RPF to 2222::3333:

#### Configuration

```
Ruijie# show ipv6 rpf 2222::3333
RPF interface: GigabitEthernet 0/1
RPF neighbor: ::
RPF route: 2222::/64
RPF type: unicast (connected)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 0
Metric: 0
```

#### Examples

## 2.16 show msf6 msc

Use this command to display entries of the IPv6 routing multicast data stream exchange table.

**show msf6 msc** [ *v6source-address* ] [ *v6group-address* ] [ *vlan-id* ]

| Parameter   | Parameter               | Description                                                                                                                 |
|-------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Description | <i>v6group-address</i>  | IPv6 address of a multicast group                                                                                           |
|             | <i>v6source-address</i> | IPv6 address of a multicast source                                                                                          |
|             | <i>vlan-id</i>          | VLAN ID of the inbound interface of the entries<br>If the value is greater than 4096, the interface is a routing interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command is used to display entries of the IPv6 routing multicast data stream exchange table. The three parameters are all optional.

If only the source address is specified and set to s1, msc entries of this source address will be displayed.

If the source address is set to s1 and the group address is set to g1, msc entries of this source address and group address will be displayed.

If the source address is set to s1, the group address is set to g1, and the VLAN ID is set to v1, then msc entries that meet these three conditions will be displayed.

You must specify these three parameters in sequence. That is, you must specify the current parameter before specifying the next.

**Configuration Examples** The following example displays entries of the IPv6 routing multicast data exchange table of source address 2000::1:

```
Ruijie# show msf6 msc 2000::1
Multicast Switching Cache Table
(2000::1, FF55::1, 1), SYNC, MTU:0, 1 OIFs
VLAN 4094(8190): 1 OPORTs, REQ: DONE
OPORT 6, MLD-SNP, REQ: DONE
```

| Field   | Description                                                                           |
|---------|---------------------------------------------------------------------------------------|
| 2000::1 | Source address of entries                                                             |
| FF55::1 | Group address of entries                                                              |
| 1       | VLAN ID of the inbound interface of the entries                                       |
| SYNC    | Indicates that the entries have been synchronized to the bottom-layer hardware.       |
| MTU     | MTU value of the entries                                                              |
| OIFs    | Number of 3-layer interfaces of the entries                                           |
| VLAN    | Indicates a 3-layer outbound interface VLAN xxx (yyy). If the 3-layer interface is an |

|            |                                                                                                                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4094(8190) | SVI interface, the value of xxx is the VLAN VID of the SVI, and the value of yyy is the VLAN vid+4096. If the 3-layer interface is a routing interface, the value of xxx is the IFINDEX of the interface+4096, and the value of yyy is the IFINDEX. This facilitates the index management of all 3-layer interfaces.                           |
| 1 OPORTs   | Number of 2-layer interfaces owned by this 3-layer exit oif                                                                                                                                                                                                                                                                                    |
| REQ: DONE  | Indicates that the oif has been set to the bottom-layer hardware. The value may be:<br>Waiting to be added. Usually it is waiting for a data stream to be triggered.<br>DEL: Being deleted.<br>DONE: Synchronized to the hardware.                                                                                                             |
| OPORT 6    | Indicates that the oif has a 2-layer interface with the interface number of 6.                                                                                                                                                                                                                                                                 |
| MLD-SNP    | Indicates that the interface is created based on MLD SNOOPING. Alternatively, the value may be one of the following options:<br>ROUTER: Indicates that the interface is created based on the 3-layer protocol.<br>INHERIT_FM_MLD_SNP: Indicates that the interface is created based on the MLD SNOOPING protocol inherited from other entries. |
| REQ: DONE  | Indicates that the interface has been set to the bottom-layer hardware. The value may be:<br>ADD: Waiting to be added. Usually it is waiting for a data stream to be triggered.<br>DEL: Being deleted.<br>DONE: Synchronized to the hardware.                                                                                                  |

## 3 IGMP Commands

### 3.1 clear ip igmp group

Use this command to clear dynamic group member information obtained from the response messages in the IGMP buffer.

**clear ip igmp group** [ *group-address* [ *interface-type* *interface-number* ] ]

| Parameter Description | Parameter               | Description                       |
|-----------------------|-------------------------|-----------------------------------|
|                       | <i>group-address</i>    | 32-bit multicast group IP address |
|                       | <i>interface-type</i>   | Interface type                    |
|                       | <i>interface-number</i> | Interface number                  |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** The IGMP buffer includes a list that contains the multicast groups that the hosts in the direct subnet join. If the device joins a group, this group will be included in this list. To delete all the entries from the IGMP buffer, use the **clear ip igmp group** command without parameters.

**Configuration Examples** The following example clears all group entries.

```
Ruijie# clear ip igmp group
```

| Related Commands | Command                       | Description |
|------------------|-------------------------------|-------------|
|                  | <b>show ip igmp groups</b>    | N/A         |
|                  | <b>show ip igmp interface</b> | N/A         |

**Platform Description** N/A

### 3.2 clear ip igmp interface

Use this command to clear the IGMP entry for the interface.

**clear ip igmp interface** *interface-type* *interface-number*

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                         |                  |
|-------------------------|------------------|
| <i>interface-type</i>   | Interface type   |
| <i>interface-number</i> | Interface number |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to clear the information on the interface that is generated when IGMP is configured. The information includes the number of report/leave packets, and group members on interfaces.

**Configuration** The following example clears the IGMP entry for the interface.

**Examples** Ruijie# clear ip igmp interface gi 0/1

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform**

**Description** N/A

### 3.3 ip igmp access-group

Use this command to control a multicast group on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp access-group** *access-list*

**no ip igmp access-group**

**default ip igmp access-group**

| Parameter Description | Parameter          | Description |
|-----------------------|--------------------|-------------|
|                       | <i>access-list</i> |             |

**Defaults** This command is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** You can add several multicast groups into the specific interfaces of the host in a subnet. These multicast groups can be controlled using **ip igmp access-group**.

 With the IGMPv3 enabled, when the multicast group accesses the control command, the extended ACL is associated. If the IGMP report information received is (S1, S2, S3...Sn, G), the corresponding ACL will be used by this command to the (0, G) for the matching check. In order to use this command normally, the (0, G) must be configured explicitly for the extended ACL so as to implement the normal filtering of (S1, S2, S3...Sn, G).

**Configuration** The following example adds the interface Ethernet 0/1 to the group 225.2.2.2.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# access-list 1 permit 225.2.2.2 0.0.0.0
Ruijie(config)# interface ethernet 0/1
```

The following example associates the group control list with the extended ACL on the interface Eth 0/1 which only processes the igmp protocol packets with source address 1.1.1.1 and group address 233.3.3.3.

```
Ruijie# configure terminal
Ruijie(config)# ip access-list extended ext_acl
Ruijie(config-ext-nacl)# permit ip host 1.1.1.1 host 233.3.3.3
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp access-group ext_acl
```

**Description**

### 3.4 ip igmp enforce-router-alert

Use this command to receive IGMP packets with **router-alert** option , and discard those without the option.

**ip igmp enforce-router-alert**

Use the **no** form of this command to receive all IGMP packets.

**no ip igmp enforce-router-alert**

Use the **default** form of this command to restore the default setting.

**default ip igmp enforce-router-alert**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| -         | -           |

|                               |                                                                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | This function is disabled by default.                                                                                                                              |
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                          |
| <b>Usage Guide</b>            | N/A                                                                                                                                                                |
| <b>Configuration Examples</b> | The following example receives IGMP packets with <b>router-alert</b> option.<br><pre>Ruijie# configure terminal Ruijie(config)# ip igmp enforce-router-alert</pre> |
| <b>Platform Description</b>   | N/A                                                                                                                                                                |

### 3.5 ip igmp enforce-source-subnet

Use this command to receive only the IGMP report packet containing the source address in the same network segment as the port.

**ip igmp enforce-source-subnet**

Use the **no** form of this command to restore the default setting.

**no ip igmp enforce-source-subnet**

Use the **default** form of this command to restore the default setting.

**default ip igmp enforce-source-subnet**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

|                               |                                                                                                                                                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | The source IP address is not checked by default.                                                                                                                                                                         |
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                                                                                |
| <b>Usage Guide</b>            | N/A                                                                                                                                                                                                                      |
| <b>Configuration Examples</b> | The following example receives only the IGMP report packet containing the source address in the same network segment as the port.<br><pre>Ruijie# configure terminal Ruijie(config)# ip igmp enforce-source-subnet</pre> |

**Platform** N/A  
**Description**

### 3.6 ip igmp immediate-leave group-list

In the IGMPversion2 and IGMPversion3 versions, use this command to shorten the delay of leaving a group. This command is used when a single receiving host is connected to a single interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp immediate-leave group-list** *access-list*

**no ip igmp immediate-leave**

**default ip igmp immediate-leave**

| Parameter Description | Parameter          | Description                                                                            |
|-----------------------|--------------------|----------------------------------------------------------------------------------------|
|                       | <i>access-list</i> | Name of access control list in the range from 1 to 199, 1,300 to 2,699, or characters. |

**Defaults** This function is disabled by default.

**Command**

**Mode** Interface configuration mode

**Usage Guide** If this command is not configured, the device will send a particular group query message upon receiving the leaving message from the interface. When the host response is timeout, the device stops forwarding packets to this interface. The length of timeout depends on the query interval of the last member and IGMP robustness variable. The default value is 2s.

If this command is configured, the device does not send a particular group query message upon receiving the leaving message from the interface. Instead, it directly removes this interface from the IGMP buffer and notifies the IGMP protocol. This will shorten the time significantly.

**Configuration Examples** The following example provides the immediate leaving function for some multicast groups. Certainly, you must make sure each interface of these multicast groups have one group member only.

```
Ruijie# configure terminal
Ruijie(config)# access-list 1 permit 225.192.20.0 0.0.0.255
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp immediate-leave group-list 1
Ruijie(config-if-Ethernet 0/1)# exit
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A

**Description**

### 3.7 ip igmp join-group

Use this command to configure the interface of the switch with host activities and adds it to a multicast group, so that the sub-switch can learn the corresponding group information. You can use this command to add an interface to a group.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp join-group** *group-address*

**no ip igmp join-group** *group-address*

**default ip igmp join-group** *group-address*

| Parameter Description | Parameter            | Description                |
|-----------------------|----------------------|----------------------------|
|                       | <i>group-address</i> | Multicast group IP address |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command enables the host activities for the IGMP interface. When the host function is enabled, the interface can initiate the report message and respond to the query message. If the IGMP function is enabled on the interface, the interface can initiate the report message, so that the interface can learn the configured group members. You can use this command to add an interface to a group.

**Configuration Examples** The following example adds a host group member manually.

```
Ruijie# configure terminal
Ruijie(config)# interface fast 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp join-group 233.3.3.3
Ruijie(config-if-Ethernet 0/1)# exit
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 3.8 ip igmp last-member-query-count

Use this command to configure the value of **last-member-query-count**.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp last-member-query-count** *number*

**no ip igmp last-member-query-count**

**default ip igmp last-member-query-count**

| Parameter Description | Parameter     | Description                                                    |
|-----------------------|---------------|----------------------------------------------------------------|
|                       | <i>number</i> | Value of the last member query count in the range from 2 to 7. |

**Defaults** The default is 2.

**Command Mode** Interface configuration mode

**Usage Guide** This command only supports IGMPv2 and IGMPv3.  
 When the interface of the device receives an IGMPv2 group leaving message, the device waits for duration of query interval multiplying **last-member-query-count** time. The device will delete information about this group member if no group member report is received within the waiting time.  
 The waiting time = last-member-query-interval \* last-member-query-count + 1/2 \* query-max-response-time

**Configuration Examples** The following example sets the value of last member query count to 3.

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0
Ruijie(config-if-Ethernet 0/1)# ip igmp last-member-query-count 3
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 3.9 ip igmp last-member-query-interval

Use this command to set the time interval of sending the group query message.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp last-member-query-interval** *interval*

**no ip igmp last-member-query-interval**

**default ip igmp last-member-query-interval**

| Parameter Description | Parameter       | Description                                                         |
|-----------------------|-----------------|---------------------------------------------------------------------|
|                       | <i>interval</i> | The interval sending the group query message in the range from 1 to |

|  |                                |
|--|--------------------------------|
|  | 255 in the unit of 0.1 second. |
|--|--------------------------------|

**Defaults** The default is 10 (1 second).

**Command Mode** Interface configuration mode

**Usage Guide** This command only supports IGMPv2 and IGMPv3.  
 When the interface of the device receives an IGMPv2 group leaving message, the device waits for duration of query interval multiplying **last-member-query-count** time. The device will delete information about this group member if no group member report is received within the waiting time.  
 The waiting time = last-member-query-interval \* last-member-query-count + 1/2 \* query-max-response-time

**Configuration** The following example sets the interval of sending the group query message to 20 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface eth 0
Ruijie(config-if-Ethernet 0/1)# ip igmp last-member-query-interval 200
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 3.10 ip igmp limit

Use this command to globally set the maximum number of IGMP group records.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp limit** *number* [ **except** *access-list* ]

**no ip igmp limit**

**default ip igmp limit**

| Parameter Description | Parameter                        | Description                                                                            |
|-----------------------|----------------------------------|----------------------------------------------------------------------------------------|
|                       | <i>number</i>                    | Maximum number of IGMP states, depending on devices                                    |
|                       | <b>except</b> <i>access-list</i> | Name of access control list in the range from 1 to 199, 1,300 to 2,699, or characters. |

**Defaults** Global: 65,536  
 Interface:1,0124

**Command** Global configuration mode/Interface configuration mode

**Mode**

**Usage Guide** Use this command to configure the maximum number of IGMP group records globally or on interfaces. The messages of the members exceeding the threshold will not be saved in the IGMP buffer and will not be forwarded. The messages of the members will be ignored if they exceed the interface or global configuration. If the configured value in global configuration mode is less than that in interface configuration mode, take the former.

**Configuration Examples** The following example sets the maximum number to 400 globally and to 300 on interfaces except ACL 1.

```
Ruijie# configure terminal
Ruijie(config)# ip igmp limit 400 except acl1
Ruijie(config)# interface eth 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp limit 300 except acl1
```

**Platform** N/A  
**Description**

### 3.11 ip igmp mroute-proxy

Use this command to configure an interface as an mroute-proxy interface that can transmit messages to its uplink ports.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp mroute-proxy** *interface-type interface-number*

**no ip igmp mroute-proxy**

**default ip igmp mroute-proxy**

**Parameter Description**

| Parameter               | Description                           |
|-------------------------|---------------------------------------|
| <i>interface-type</i>   | Name of the relevant uplink interface |
| <i>interface-number</i> |                                       |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Use the **ip igmp proxy-service** command to set the uplink interface as the **proxy-service** interface. Use the **ip igmp mroute-proxy** command to set the downlink interface as the **mroute-proxy** interface.

IGMP query packets are forwarded from the **proxy-service** interface to the **mroute-proxy** interface. IGMP report packets are forward reversely.

**Configuration** The following example configures E0/1 as **proxy-service** E0/2 as **mroute-proxy**.

**Examples**

```
Ruijie(config)# interface eth 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp proxy-service
Ruijie(config-if-Ethernet 0/1)# exit
Ruijie(config)# interface eth 0/2
Ruijie(config-if-Ethernet 0/2)# ip igmp mroute-proxy
```

**Platform**

N/A

**Description**

## 3.12 ip igmp proxy-service

Use this command to enable the service function of all downlink **mroute-proxy** ports.

If you run this command on an interface, the interface becomes the uplink port of the corresponding **mroute-proxy** that associates its downlink ports and maintains the group information reported by the downlink ports.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp proxy-service**

**no ip igmp proxy-service**

**default ip igmp proxy-service**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

N/A

**Command Mode**

Interface configuration mode

**Usage Guide**

Use the **ip igmp proxy-service** command to set the uplink interface as the **proxy-service** interface. Use the **ip igmp mroute-proxy** command to set the downlink interface as the **mroute-proxy** interface.

The command can configure at most 32 proxy-service ports. The number of interface with IGMP Proxy enabled is limited by the supported multicast interface number. When receiving a query message, the **proxy-service** port responds according to the IGMP group member information maintained by the port itself. The member information maintained by the **proxy-service** port is

collected from the interface configured with **mroute-proxy**. Therefore, if a port is configured with proxy-service, the port performs the host activities, but not the device activities.

If **switch port** operation is performed on an interface with proxy-service command configured, the **ip igmp mroute-proxy interface** command configured on the associated downlink ports is automatically deleted.

**Configuration** The following example configures E0/1 as **proxy-service** and E0/2 as **mroute-proxy**.

**Examples**

```
Ruijie(config)# interface eth 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp proxy-service
Ruijie(config-if-Ethernet 0/1)# exit
Ruijie(config)# interface eth 0/2
Ruijie(config-if-Ethernet 0/2)# ip igmp mroute-proxy
```

### 3.13 ip igmp query-interval

Use this command to configure the query interval of an ordinary member.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp query-interval** *seconds*

**no ip igmp query-interval**

**default ip igmp query-interval**

**Parameter Description**

| Parameter      | Description                                                                                 |
|----------------|---------------------------------------------------------------------------------------------|
| <i>seconds</i> | Query interval of ordinary member, in the range is from 1 to 18,000 in the unit of seconds. |

**Defaults**

The default is 125 seconds.

**Command Mode**

Interface configuration mode

**Usage Guide**

**Configuration Examples** The following example configures the query interval of ordinary member to 120 seconds on the interface Ethernet 0.

```
Ruijie(config-if)# ip igmp query-interval 120
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A

**Description**

### 3.14 ip igmp query-max-response-time

Use this command to configure the maximum response interval.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp query-max-response-time** *seconds*

**no ip igmp query-max-response-time**

**default ip igmp query-max-response-time**

| Parameter Description | Parameter | Description    |
|-----------------------|-----------|----------------|
|                       |           | <i>seconds</i> |

**Defaults** The default is 10 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** This command controls the interval for the respondent to respond the query message before the device deletes the group information.

**Configuration Examples** The following example configures the maximum response interval to 20 seconds on the interface Ethernet 0.

```
Ruijie(config-if-Ethernet 0/1)# ip igmp query-max-response-time 20
```

| Related Commands | Command | Description |

**Platform** N/A

**Description**

### 3.15 ip igmp query-timeout

Use this command to configure the time the device waits before it takes over as the querier.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp query-timeout** *seconds*  
**no ip igmp query-timeout**  
**default ip igmp query-timeout**

| Parameter Description | Parameter      | Description                                                                                                    |
|-----------------------|----------------|----------------------------------------------------------------------------------------------------------------|
|                       | <i>seconds</i> | Time the device waits before it takes over as the querier, in the range from 60 to 300 in the unit of seconds. |

**Defaults** The default is 255 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** This device becomes the querier if no query packet is received in this duration.

**Configuration Examples** The following example configures the time the device waits before it takes over as the querier to 200 s seconds on the interface Ethernet 0/1.

```
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp query-timeout 200
```

**Platform Description** N/A

### 3.16 ip igmp robustness-variable

Use this command to change the value of the robustness variable.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp robustness-variable** *number*  
**no ip igmp robustness-variable**  
**default ip igmp robustness-variable**

| Parameter Description | Parameter     | Description                                                |
|-----------------------|---------------|------------------------------------------------------------|
|                       | <i>number</i> | The value of robustness variable, in the range from 2 to 7 |

**Defaults** The default is 2.

**Command** Interface configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the value of robustness variable to 3.

**Examples**

```
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp robustness-variable 3
```

**Related Commands**

**Description**

### 3.17 ip igmp send-router-alert

Use this command to send IGMP report packets with the Router Alert option.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp send-router-alert**

**no ip igmp send -router-alert**

**default ip igmp send -router-alert**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| -         | -           |

**Defaults** The Router Alert option is not carried in IGMP packets by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** N.A

**Configuration** The following example sends IGMP report packets with the Router Alert option.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip igmp send-router-alert
```

**Platform** N/A

**Description**

### 3.18 ip igmp ssm-map enable

Use this command to enable the **igmp ssm-map** function in the global configuration mode.

Use the **no** form of this command to restore the default setting.

**ip igmp ssm-map enable**

**no ip igmp ssm-map enable**

**default ip igmp ssm-map enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** If this command is configured, the dynamically learned group information is added forcibly to the associated source record. This command is usually used together with the **ip igmp ssm-map static** command.

**Configuration Examples** The following example enables the **igmp ssm-map** function in the global configuration mode.

```
Ruijie(config)# ip igmp ssm-map enable
Ruijie(config)# ip igmp ssm-map static 11 192.168.2.2.
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 3.19 ip igmp ssm-map static

Use this command to map the static **ssm-map** source IP address to the group records.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp ssm-map static** *access-list source-address*

**no ip igmp ssm-map static** *access-list source-address*

**default ip igmp ssm-map enable** *access-list source-address*

| Parameter Description | Parameter          | Description                                                  |
|-----------------------|--------------------|--------------------------------------------------------------|
|                       | <i>access-list</i> | ACL name in the range 1 to 99, 1,300 to 1,999 or characters. |

|                       |                                             |
|-----------------------|---------------------------------------------|
| <i>source-address</i> | Unicast address mapped to the group record. |
|-----------------------|---------------------------------------------|

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used together with the **ip igmp ssm-map enable** and **ip igmp ssm-map static** command. After configuration, the port maps the corresponding source IP address to all received messages below **v3**.

**Configuration Examples** The following example maps the source address 192.168.2.2 to all group records permitted by ACL 11.

```
Ruijie(config)# ip igmp ssm-map enable
Ruijie(config)# ip igmp ssm-map static 11 192.168.2.2.
```

| Related Commands | Command | Description |

**Platform Description** N/A

## 3.20 ip igmp static-group

Use this command to directly add an interface to a group.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp static-group** *group-address*

**no ip igmp static-group** *group-address*

**default ip igmp static-group** *group-address*

| Parameter Description | Parameter            | Description |
|-----------------------|----------------------|-------------|
|                       | <i>group-address</i> |             |

**Defaults** The switch is not added to a multicast group by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command directly adds an interface to a multicast group. The difference from **join-group** is that it directly adds an interface to the group without interacting with a report message. You can use this command to add an interface to a group. The added interfaces by this command can only be deleted by using the **no ip igmp static-group**

command.

**Configuration** The following example adds a host group member.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp static-group 236.6.6.6
```

## 3.21 ip igmp version

Use this command to set the version number of IGMP to be used on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp version { 1 | 2 | 3 }**

**no ip igmp version**

**default ip igmp version**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| 1         | IGMP v1     |
| 2         | IGMP v2     |
| 3         | IGMP v3     |

**Defaults** The default is IGMPv2.

**Command  
Mode** Interface configuration mode

**Usage Guide** Use this command to globally configure the IGMP version. It should be noted that IGMP will reset after configuration.

**Configuration** The following example sets the version number to 3.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ip igmp version 3
```

## 3.22 show ip igmp groups

Use this command to display the groups directly connected to the device and the group information learnt from IGMP.

**show ip igmp groups** [ *interface-type interface-number* ] [ *group-address* ] [ **detail** ]

| Parameter Description | Parameter               | Description                                                                                                                            |
|-----------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>group-address</i>    | 32-bit multicast group IP address, namely Category D address. 8 bits are in one group in decimal form. Groups are separated with dots. |
|                       | <i>interface-type</i>   | Interface type                                                                                                                         |
|                       | <i>interface-number</i> | Interface number                                                                                                                       |
|                       | <b>detail</b>           | Displays the detailed information                                                                                                      |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command without any parameters to display group address, interface type, and information about all the multicast groups directly connected to the interface. Information about a specific group is displayed if a group address is added to the command.

**Configuration** The following example displays information about all the groups.

### Examples

```
Ruijie# show ip igmp groups
IGMP Connected Group Membership
Group Address  Interface  Uptime  Expires  Last Reporter
224.0.1.1     eth2      00:00:09  00:04:17  10.10.0.82
224.0.1.24    eth2      00:00:06  00:04:14  10.10.0.84
224.0.1.40    eth2      00:00:09  00:04:15  10.10.0.91
224.0.1.60    eth2      00:00:05  00:04:15  10.10.0.7
239.255.255.250 eth2      00:00:12  00:04:15  10.10.0.228
239.255.255.254 eth2      00:00:08  00:04:13  10.10.0.84
```

The following example displays detailed information about a specific group.

```
Ruijie# show ip igmp groups 224.1.1.1 detail
Interface      : eth1
Group: 224.1.1.1
Uptime: 00:00:42
Group mode: Include
Last reporter: 192.168.50.111
```

```
TIB-A Count: 2
TIB-B Count: 0
Group source list: (R - Remote, M - SSM Mapping)
Source Address Uptime v3 Exp Fwd Flags
192.168.55.55 00:00:42 00:03:38 Yes R
192.168.55.66 00:00:42 00:03:38 Yes R
```

### 3.23 show ip igmp interface

Use this command to display the information of this interface.

**show ip igmp interface** [ *interface-type interface-number* ]

**Parameter Description**

| Parameter               | Description       |
|-------------------------|-------------------|
| <i>interface-type</i>   | Interface type.   |
| <i>interface-number</i> | Interface number. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Run this command without any parameter, and all interface information is displayed by default.

**Configuration Examples** The following example displays the information of all the interfaces.

```
Ruijie# show ip igmp interface
Interface vlan 1(Index 4294967295)
IGMP Active, Non-Querier, Version 3 (default)
IGMP querying router is 0.0.0.0
IGMP query interval is 125 seconds
IGMP querier timeout is 255 seconds
IGMP max query response time is 10 seconds
Last member query response interval is 1000 milliseconds
Group Membership interval is 260 seconds
```

### 3.24 show ip igmp ssm-mapping

Use this command to display the **ssm-map** information of the IGMP configuration.

**show ip igmp ssm-mapping** [ *group-address* ]

| Parameter<br>Description | Parameter | Description          |
|--------------------------|-----------|----------------------|
|                          |           | <i>group-address</i> |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Run this command without any parameter, and all SSM-MAP information is displayed.

**Configuration** The following example displays the **ssm-map** configuration information.

**Examples**

```
Ruijie#show ip igmp ssm-mapping 233.3.3.3
Group address: 233.3.3.3
Database      : Static
Source list   : 192.3.3.3
               : 3.3.3.3
```

## 4 MLD Commands

### 4.1 clear ipv6 mld group

Use this command to clear the dynamic group member learned by MLD protocol.

**clear ipv6 mld group** [ *group-address* ] [ *interface-type interface-number* ]

| Parameter Description | Parameter               | Description                                |
|-----------------------|-------------------------|--------------------------------------------|
|                       | <i>group-address</i>    | IPv6 multicast group address with 128 bits |
|                       | <i>interface-type</i>   | The associated interface type              |
|                       | <i>interface-number</i> | The associated interface number            |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** MLD maintains a list of the multicast groups to be added to the host in the directly-connected sub-net. Use the **clear ipv6 mld group** command to remove all dynamic group member record from the MLD group member list.

**Configuration** The following example clears all group records.

**Examples** Ruijie# `clear ipv6 mld group`

The following example clears one group record.

Ruijie# `clear ipv6 mld group ff1e::100`

The following example s clears the record on a specified interface.

Ruijie# `clear ipv6 mld group ff1e::100 interfa fa0/1`

| Related Commands | Command                        | Description |

**Platform** N/A

**Description**

### 4.2 clear ipv6 mld interface

Use this command to clear all MLD statistical information and the group member records on the interface.

**clear ipv6 mld interface** *interface-type interface-number*

| Parameter Description | Parameter               | Description        |
|-----------------------|-------------------------|--------------------|
|                       | <i>interface-type</i>   | The interface type |
|                       | <i>interface-number</i> | The interface ID   |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear all group information and some packet statistical information learned by LDP on the interface. Those packet statistical information include the number of the received report packets, the number of the done packets and the the number of the group members on the interface.

**Configuration Examples** The following example clears all MLD statistical information and the group member records on the interface.

```
Ruijie# clear ipv6 mld interface fa 1/1
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 4.3 ipv6 mld access-group

Use this command to filter the specific requested group on the interface. Only the report packets in accordance with the corresponding ACL are allowed to be processed.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld access-group** *access-list*

**no ipv6 mld access-group**

**default ipv6 mld access-group**

| Parameter Description | Parameter          | Description       |
|-----------------------|--------------------|-------------------|
|                       | <i>access-list</i> | The IPv6 ACL name |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to filter some groups on the interface and associate with the corresponding ACLs. The correspondent ACL deny report packets will be discarded. This command supports the extended ACL and the source record information of the MLDv2 packets can be filtered.

 The multicast group access control command is associated with the extended ACL. When the received MLD report message is (S1,S2,S3...Sn,G), use this command to match and check the (0,G) message using the corresponding ACL. To this end, a (0,G) must be configured for the extended ACL to filter the (S1,S2,S3...Sn,G).

**Configuration Examples** The following example enables the group information carried in the report packets to be in accordance with acl for the normal handling on the interface Eth0/1.

```
Ruijie(config)#ipv6 access-list acl
Ruijie(config-ipv6-acl)#permit ipv6 ::/64 ff66::100/64
Ruijie(config-ipv6-acl)#permit ipv6 2222::3333/64 ff66::100/64
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1-Ethernet 0/1)# ipv6 mld access-group acl
```

**Platform** N/A  
**Description**

## 4.4 ipv6 mld immediate-leave group-list

Use this command to set the immediate-leave mechanism. With this command configured, the group within the range of group-list, will not send the query packet for the specific group and will remove this group from the group member list immediately after receiving the corresponding done packets. This function is used in the condition that there is only one multicast source that receives the host request on an interface. Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld immediate-leave group-list** *access-list*

**no ipv6 mld immediate-leave group-list**

**default ipv6 mld immediate-leave group-list**

**Parameter Description**

| Parameter          | Description       |
|--------------------|-------------------|
| <i>access-list</i> | The IPv6 ACL name |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Without this command configured, when the device receives the MLD leave packets, the request packets for the specific groups will be sent. If there is still no host reply within the response time, the device will remove the corresponding group record from the group member list. The timeout interval is determined by the last member query interval and the MLD robustness variable, and the default value is 2 seconds.

With this command configured, when the device receives the MLD leave packets, it will not send the request packets for the specific groups, but remove the group information immediately, which reduces the leave delay greatly in the condition that there is only one host connecting to the interface.

**Configuration** The following example configures the immediate-leave function.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)#ipv6 access-list acl
Ruijie(config-ipv6-acl)#permit ipv6 2222::3333/64 ff66::100/64
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1-Ethernet 0/1)# ipv6 mld immediate-leave
group-list acl
```

**Description**

## 4.5 ipv6 mld join-group

Use this command to configure the host action for the switch interface and add the related multicast group to the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld join-group** *group-address*

**no ipv6 mld join-group** *group-address*

**default ipv6 mld join-group** *group-address*

**Parameter  
Description**

| Parameter            | Description                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------|
| <i>group-address</i> | The IPv6 non-management multicast group address, which cannot start with 0xFF*1, 0xFF*2, and 0xFF3* |

**Defaults** The interface is not added to any group by default.

**Command  
Mode** Interface configuration mode

**Usage Guide** Use this command to enable the MLD host action on the interface. The interface can not only send the packets initiatively, but also reply to the query packets.  
Use this command if it is necessary to join a group member to the interface.

**Configuration** The following example adds the host group member:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1-Ethernet 0/1)# ipv6 mld join-group ff55::100
```

## 4.6 ipv6 mld last-member-query-count

Use this command to set the last-member-query-count number.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld last-member-query-count** *number*

**no ipv6 mld last-member-query-count**

**default ipv6 mld last-member-query-count**

**Parameter Description**

| Parameter     | Description                                                    |
|---------------|----------------------------------------------------------------|
| <i>number</i> | The last member query count number. The valid range is 2 to 7. |

**Defaults** The default is 2.

**Command Mode** Interface configuration mode

**Usage Guide** With the MLD leave packets received on the interface, if there is no group reply within the timeout interval, this group will be removed from the MLD group member list on the interface. The timeout interval is the query interval for the specific group (multiplied by the value of **mld last-member-query-count**) plus half the reply time.

**Configuration** The following example sets the last-member-query-count number to 3.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ipv6 mld last-member-query-count 3
```

**Description**

## 4.7 ipv6 mld last-member-query-interval

Use this command to set the time interval of sending the query packets to the specific group.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld last-member-query-interval** *interval*

**no ipv6 mld last-member-query-interval**

**default ipv6 mld last-member-query-interval**

| <b>Parameter Description</b> | Parameter       | Description                                          |
|------------------------------|-----------------|------------------------------------------------------|
|                              | <i>interval</i> | The valid range is 1-255 in the unit of 0.1 seconds. |

**Defaults** The default is 10 seconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide** With the MLD leave packets received on the interface, if there is no group reply within the timeout interval, this group will be removed from the MLD group member list on the interface. The timeout interval is the query interval for the specific group(multiplied by the value of **mld last-member-query-count**) plus half the reply time.

**Configuration** The following example sets the mld last-member-query-interval to 2 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ipv6 mld last-member-query-interval 20
```

**Description**

## 4.8 ipv6 mld limit

Use this command to enable to learn the max-number of the group member through the MLD

protocol.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld limit** *number* [ **except** *access-list* ]

**no ipv6 mld limit** *number* [ **except** *access-list* ]

**default ipv6 mld limit** *number* [ **except** *access-list* ]

| Parameter Description | Parameter                        | Description                                               |
|-----------------------|----------------------------------|-----------------------------------------------------------|
|                       | <i>number</i>                    | The maximum number of the group member learned by the MLD |
|                       | <b>except</b> <i>access-list</i> | (Optional) The ACL beyond the configured mld limit        |

**Defaults**  
Interface: 1,024  
Global: 65,536

**Command Mode**  
Interface configuration mode/Global configuration mode

**Usage Guide**  
Use this command to set the max-number of the group members learned through the MLD in the global configuration mode. If the group member number has exceeded the limit, the received report packets later will be discarded and fail to form the group record.  
If the except list has also been set at the same time, the group member packets, including the packets in the access-list, will be free from the member number limit.  
This command can also be used in the interface configuration mode. The configurations in two different configuration modes are independent. If the number limit in the global configuration mode is lower than the one in the interface configuration mode, the former configuration takes precedence.

**Configuration Examples**  
The following example sets the MLD limit to 400, but the configured ACL can still learn.

```
Ruijie(config-if)# ipv6 mld limit 300 except acl
Ruijie# configure terminal
Ruijie(config)# ipv6 mld limit 400 except acl1
Ruijie(config)# interface eth 0/1
Ruijie(config-if-Ethernet 0/1)# ipv6 mld limit 300 except acl1
```

## 4.9 ipv6 mld mroute-proxy

Use this command to enable the interface to forward the packets to the correspondent connected interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld mroute-proxy** *interface-type interface-number*

**no ipv6 mld mroute-proxy**

**default ipv6 mld mroute-proxy**

| Parameter Description | Parameter                                        | Description                           |
|-----------------------|--------------------------------------------------|---------------------------------------|
|                       | <i>interface-type</i><br><i>interface-number</i> | The correspondent connected interface |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Use the **ipv6 mld proxy-service** command to configure the uplink interface as **proxy-service** one. Use the **ipv6 mld mroute-proxy** command to configure the downlink interface as **mroute-proxy** one. After the connected interface has been configured as the proxy-service interface, it can forward the MLD packets sent from other members.

**Configuration** The following example sets the interface as the mroute-proxy interface and enables multicast proxy.

**Examples**

```
Ruijie(config)# interface eth 0/1
Ruijie(config-if-Ethernet 0/1)# ipv6 mld proxy-service
Ruijie(config-if-Ethernet 0/1)# exit
Ruijie(config)# interface eth 0/2
Ruijie(config-if-Ethernet 0/2)# ipv6 mld mroute-proxy eth 0/1
```

**Description**

## 4.10 ipv6 mld proxy-service

Use this command to enable the proxy-service function for the interface connected with the mroute-proxy interface in the downward direction. After configuring this command, the interface becomes the one connected with the mroute-proxy in the upward direction, and associates with and maintains the group information from the interfaces in the downward direction. Use the **no** or **default** form of this command to disable the default setting.

**ipv6 mld proxy-service**

**no ipv6 mld proxy-service**

**default ipv6 mld proxy-service**

| <b>Command Mode</b>           | Interface configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |
| <b>Usage Guide</b>            | <p>Use the <b>ipv6 mld proxy-service</b> command to configure the uplink interface as <b>proxy-service</b> one. Use the <b>ipv6 mld mroute-proxy</b> command to configure the downlink interface as <b>mroute-proxy</b> one. The configurable max-number limit is 32. The number of the interfaces with MLD Proxy enabled is limited by the number multicast interfaces supported device. After receiving the query packet, the proxy-service interface replies according to the member information, which are collected from the mroute-proxy interface and maintained by the proxy-service interface itself. With proxy-service configured, this interface owns the host action rather than the router action.</p> <p>The <b>ipv6 mld mroute-proxy interface</b> command configuration on the associated interface in the downward direction is removed automatically if the switchport operation is performed on the interfaces.</p> |                    |
| <b>Configuration Examples</b> | <p>The following example sets the interface proxy-service and enables multicast proxy.</p> <pre>Ruijie(config)# interface eth 0/1 Ruijie(config-if-Ethernet 0/1)# ipv6 mld proxy-service Ruijie(config-if-Ethernet 0/1)# exit Ruijie(config)# interface eth 0/2 Ruijie(config-if-Ethernet 0/1-Ethernet 0/2)# ipv6 mld mroute-proxy eth 0/1</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                    |
| <b>Related Commands</b>       | <b>Command</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <b>Description</b> |
|                               | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | N/A                |
| <b>Platform Description</b>   | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |

## 4.11 ipv6 mld querier-timeout

Use this command to set the querier alive period.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld querier-timeout** *seconds*

**no ipv6 mld querier-timeout**

**default ipv6 mld querier-timeout**

|                  |                  |                    |
|------------------|------------------|--------------------|
| <b>Parameter</b> | <b>Parameter</b> | <b>Description</b> |
|------------------|------------------|--------------------|

|                    |                |                                                                               |
|--------------------|----------------|-------------------------------------------------------------------------------|
| <b>Description</b> |                |                                                                               |
|                    | <i>seconds</i> | The querier alive period, in the range from 60 to 300 in the unit of seconds. |

**Defaults** The default is 255 seconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide** After the querier sends the query packet, the querier will wait to receive the query packet sent by another querier within the alive period. If no packet is received by the first querier within the alive period, then the first querier takes itself as the only querier on the network segment.

**Configuration** The following example sets the querier alive period to 200 seconds.

**Examples** Ruijie(config-if-Ethernet 0/1)# ipv6 mld querier-timeout 200

|                         |                |                    |
|-------------------------|----------------|--------------------|

**Platform** N/A

**Description**

## 4.12 ipv6 mld query-interval

Use this command to set the query interval for the general member.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld query-interval** *seconds*

**no ipv6 mld query-interval**

**default ipv6 mld query-interval**

|                              |                  |                                                                                                  |
|------------------------------|------------------|--------------------------------------------------------------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b> | <b>Description</b>                                                                               |
|                              | <i>seconds</i>   | The query interval for the general member, in the range from 1 to 18,000 in the unit of seconds. |

**Defaults** The default is 125 seconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide**

**Configuration** The following example sets the query-interval for the general member on the interface Ethernet 0/1.

**Examples** `Ruijie(config-if-Ethernet 0/1)# ipv6 mld query-interval 120`

| Related Commands | Command | Description |

**Platform** N/A

**Description**

## 4.13 ipv6 mld query-max-response-time

Use this command to set the maximum response time.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld query-max-response-time** *seconds*

**no ipv6 mld query-max-response-time**

**default ipv6 mld query-max-response-time**

| Parameter Description | Parameter      | Description |
|-----------------------|----------------|-------------|
|                       | <i>seconds</i> |             |

**Defaults** The default is 10 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to control the maximum response time of the host after the device sends the query packets. If there is no response within the maximum response time, MLD will remove the corresponding group from the group member list.

**Configuration Examples** The following example sets the maximum query response time on the interface Ethernet 0/1.

**Examples** `Ruijie(config-if-Ethernet 0/1)# ipv6 mld query-max-response-time 20`

| Related Commands | Command | Description |

**Description**

## 4.14 ipv6 mld robustness-variable

Use this command to set querier robustness value.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld robustness-variable** *number*

**no ipv6 mld robustness-variable**

**default ipv6 mld robustness-variable**

| Parameter Description | Parameter     | Description                                                  |
|-----------------------|---------------|--------------------------------------------------------------|
|                       | <i>number</i> | Sets the querier robustness value, in the range from 2 to 7. |

**Defaults** The default is 2.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the querier robustness value to 3.

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ipv6 mld robustness-variable 3
```

| Related Commands | Command | Description |

## 4.15 ipv6 mld ssm-map enable

Use this command to enable the mld ssm-map function.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld ssm-map enable**

**no ipv6 mld ssm-map enable**

**default ipv6 mld ssm-map enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

- Defaults** This function is disabled by default.
- Command** Global configuration mode
- Mode**
- Usage Guide** With this command configured, the group information dynamically learned will be added to the related source record forcibly. Usually, this command is set with the **ipv6 mld ssm-map static** command.

**Configuration** The following example enables the mld ssm-map function in the global configuration mode.

**Examples**

```
Ruijie(config)# ipv6 mld ssm-map enable
Ruijie(config)# ipv6 mld ssm-map static 11 4444::1234
```

**Related Commands**

**Platform** N/A

**Description**

## 4.16 ipv6 mld ssm-map static

Use this command to set the mld ssm-map static mapping source record in the global configuration mode.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld ssm-map static** *access-list source-address*

**no ipv6 mld ssm-map static** *access-list source-address*

**default ipv6 mld ssm-map static** *access-list source-address*

**Parameter Description**

| Parameter             | Description                                            |
|-----------------------|--------------------------------------------------------|
| <i>access-list</i>    | Sets the IPv6 ACL name.                                |
| <i>source-address</i> | Sets the unicast address for the group record mapping. |

- Defaults** There is no mapping source address by default.
- Command** Global configuration mode
- Mode**
- Usage Guide** This command is used with the **ipv6 mld ssm-map enable** command. With this command configured, the received mldv1 packets are mapped to the correspondent source record.
- Configuration** The following example maps all group record of the ACL name to the source address 4444::1234.

**Examples**

```
Ruijie(config)# ipv6 mld ssm-map enable
Ruijie(config)# ipv6 mld ssm-map static te 4444::1234
```

**Description**

## 4.17 ipv6 mld static-group

Use this command to add an interface to a group statically.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld static-group** *group-address*

**no ipv6 mld static-group** *group-address*

**default ipv6 mld static-group** *group-address*

| Parameter Description | Parameter | Description          |
|-----------------------|-----------|----------------------|
|                       |           | <i>group-address</i> |

**Defaults** The interface is not added to any group statically.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** Use this command to add a multicast group to the interface directly. The difference from the join-group is that the packet interaction is not necessary.

Use this command when it is necessary to add a group member to the interface. It is worth mentioning that only the **no ipv6 mld static-group** command can be used to delete the group, but not the **clear** command.

**Configuration** The following example adds interface Eth0/1 to group ff55::3 statically.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ipv6 mld static-group ff55::3
```

## 4.18 ipv6 mld version

Use this command to set the MLD version number on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld version** { 1 | 2 }

**no ipv6 mld version**

**default ipv6 mld version**

| Parameter Description | Parameter | Description                  |
|-----------------------|-----------|------------------------------|
|                       | { 1   2 } | Sets the MLD version number. |

**Defaults** The default is 2.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to control the MLD version number.

**Configuration Examples** The following example sets the MLD version 1.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface ethernet 0/1
Ruijie(config-if-Ethernet 0/1)# ipv6 mld version 1
```

| Related Commands | Command | Description |

**Platform Description** N/A

## 4.19 show ipv6 mld groups

Use this command to display the group connected with the switch and the group information learned from the MLD.

**show ipv6 mld groups** [ *group-address* | *interface-type interface-number* ] [ **detail** ]

| Parameter Description | Parameter               | Description                                        |
|-----------------------|-------------------------|----------------------------------------------------|
|                       | <i>group-address</i>    | Sets the IPv6 multicast group address in 128 bits. |
|                       | <i>interface-type</i>   | Sets the interface type.                           |
|                       | <i>interface-number</i> | Sets the interface number.                         |
|                       | <b>detail</b>           | Displays the information in detail.                |

|  |                                     |
|--|-------------------------------------|
|  | Displays all the group information. |
|--|-------------------------------------|

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Interface configuration mode

**Usage Guide** Use this command without the parameters to display the information including the group address, the interface type and the multicast group information. Use this command with a parameter to display the information on a specific group.

**Configuration** The following example displays all group information.

**Examples**

```
Ruijie# show ipv6 mld groups
MLD Connected Group Membership
Group Address Interface Uptime Expires Last Reporter
ff66::1 VLAN1 00:10:57 00:02:16 fe80::2d0:f8ff:fe22:3378
```

The following example displays the detailed information.

```
Ruijie# show ipv6 mld groups detail
Interface:      VLAN 1
Group:          ff66::1
Uptime:         00:10:26

## 4.20 show ipv6 mld interface

Use this command to display the configurations on the interface.

**show ipv6 mld interface** [ interface-type interface-number ]

**Parameter Description**

| Parameter               | Description                |
|-------------------------|----------------------------|
| <i>interface-type</i>   | Sets the interface type.   |
| <i>interface-number</i> | Sets the interface number. |

**Defaults** N/A

**Command** User EXEC mode/Privileged EXEC mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example displays the state information of all interfaces.

**Examples**

```
Ruijie# show ipv6 mld interface
Interface VLAN 2 (Index 4098)
  MLD Enabled, Inactive, Version 2 (default)
  MLD interface limit is 1024
  MLD interface has 0 group-record states
  MLD interface has 1 join-group records
  MLD interface has 0 static-group records
  MLD activity: 0 joins, 0 leaves
  MLD query interval is 125 seconds
  MLD querier timeout is 255 seconds
  MLD max query response time is 10 seconds
  Last member query response interval is 10 (1/10s)
  Last member query count is 2
  Group Membership interval is 260
  Robustness Variable is 2
```

## 4.21 show ipv6 mld ssm-mapping

Use this command to display the mapping information of the source address for the group record.

**show ipv6 mld ssm-mapping** [ *group-address* ]

**Parameter  
Description**

| Parameter            | Description                 |
|----------------------|-----------------------------|
| <i>group-address</i> | Displays the group address. |

**Defaults** N/A

**Command** User EXEC mode/Privileged EXEC mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example displays the state information of all interfaces.

**Examples**

```
Ruijie# show ipv6 mld interface
Interface VLAN 2 (Index 4098)
  MLD Enabled, Inactive, Version 2 (default)
  MLD interface limit is 1024
  MLD interface has 0 group-record states
  MLD interface has 1 join-group records
  MLD interface has 0 static-group records
  MLD activity: 0 joins, 0 leaves
  MLD query interval is 125 seconds
  MLD querier timeout is 255 seconds
  MLD max query response time is 10 seconds
  Last member query response interval is 10 (1/10s)
  Last member query count is 2
  Group Membership interval is 260
  Robustness Variable is 2
```

## 5 PIM-DM Commands

### 5.1 clear ip pim dense-mode track

Use this command to clear the statistics of PIM-DM packets.

**clear ip pim dense-mode track**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to reconfigure the start time of the statistics and clear the PIM packet counter.

**Configuration Examples** The following example clears the statistics of PIM-DM packets.

```
Ruijie# clear ip pim dense-mode track
```

| Related Commands | Command                             | Description                                 |
|------------------|-------------------------------------|---------------------------------------------|
|                  | <b>show ip pim dense-mode track</b> | Displays the statistics of the PIM packets. |

**Platform** N/A

**Description**

### 5.2 ip pim dense-mode

Use this command to enable PIM-DM on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim dense-mode**

**no ip pim dense-mode**

**default ip pim dense-mode**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

### Usage Guide

- i Before enabling the PIM-DM, enable the multicast forwarding function in the global configuration mode. Otherwise, the multicast data packet cannot be forwarded even the PIM-DM is enabled.
- i Once the PIM-DM is enabled, the IGMP is enabled automatically on the interface without manual configuration.
- i During the execution of this command, if the prompt "Failed to enable PIM-DM on <Interface Name>, resource temporarily unavailable, please try again" appears, re-execute this command.
- i During the execution of this command, if the prompt "PIM-DM Configure failed! VIF limit exceeded in NSM!!!" appears; it indicates the allowed configured multicast interface number exceeds the upper limit of the multicast interfaces. In this case, if it's still necessary to enable the PIM-DM on the interface, delete the unnecessary PIM-DM, PIM-SM or DVMRP interfaces.
- i It is not recommended to configure different IPv4 multicast routing protocols on different interfaces of a device.

**Configuration** The following example enables PIM-DM on the interface.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim dense-mode
```

## 5.3 ip pim dense-mode passive

Use this command to enable PIM-DM PASSIVE.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim dense-mode passive**

**no ip pim dense-mode passive**

**default ip pim dense-mode passive**

### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

- Defaults** PIM-DM PASSIVE is disabled by default.
- Command** Interface configuration mode
- Mode**
- Usage Guide** Please configure multicast route forwarding in global configuration mode before enabling PIM-DM PASSIVE.
- When PIM-DM PASSIVE is enabled, IGMP is enabled on each interface automatically.
- Enabled with PIM-DM PASSIVE, the interface neither receives nor sends PIM packets. Instead, it forwards multicast packets. PIM-DM PASSIVE is generally configured on the device of the stub area, so as to avoid floods of PIM hello packets.

**Configuration** The following example enables PIM-DM PASSIVE on interface fastethernet 0/1.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim dense-mode passive
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A

**Description**

## 5.4 ip pim dense-mode subvlan

Use this command to enable PIM-DM on the Super VLAN interface. Use the **no** or **default** form of this command is to restore the default setting.

**ip pim dense-mode subvlan [ all | vid ]**

**no ip pim dense-mode subvlan**

**default ip pim dense-mode subvlan**

| Parameter          | Parameter  | Description                              |
|--------------------|------------|------------------------------------------|
| <b>Description</b> | <b>all</b> | Sends PIM packets to all sub VLANs.      |
|                    | <i>vid</i> | Sends PIM packets to the specified VLAN. |

**Defaults** PIM-DM is disabled on the Super VLAN interface by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** In general, a super VLAN includes many sub VLANs. If the PIM-DM protocol is enabled on the interfaces of the super VLAN, PIM-DM multicast packets will be replicated and sent to all sub VLANs. As a result, the traffic may exceed the device capability, causing protocol flapping. The Super VLAN

interface is disabled with PIM-DM generally. Use this command to enable PIM-DM on the Super VLAN interface to send PIM packets to all sub VLANs or the specified sub VLAN.

**Configuration Examples** The following example enables PIM-DM on the Super VLAN interface and sends PIM packets to sub VLAN 200.

```
Ruijie# configure terminal
Ruijie(config)# interface vlan 100
Ruijie(config-if-vlan 100)# ip pim dense-mode subvlan 200
```

## 5.5 ip pim neighbor-filter

Use this command to enable the neighbor filtering on the interface. Use the **no** or **default** form of this command is to restore the default setting.

**ip pim neighbor-filter** *access-list*

**no ip pim neighbor-filter** *access-list*

**default ip pim neighbor-filter** *access-list*

**Parameter Description**

| Parameter          | Description                                                                         |
|--------------------|-------------------------------------------------------------------------------------|
| <i>access-list</i> | Access control list supporting numerical ACL in the range from 1 to 99 and name ACL |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** If the neighbor filtering is set, PIM-DM will not establish the peering relationship with this neighbor or will terminate the established peering relationship with this neighbor once the neighbor is denied by the filtering access list.

**Configuration Examples** The following example enables the neighbor filtering on the interface.

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim neighbor-filter 14
```

## 5.6 ip pim override-interval

Use this command to reconfigure the override-interval of the hello message.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim override-interval** *interval-milliseconds*

**no ip pim override-interval**

**default ip pim override-interval**

|                              |                              |                                                           |
|------------------------------|------------------------------|-----------------------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b>             | <b>Description</b>                                        |
|                              | <i>interval-milliseconds</i> | In the range from 1 to 65,535 in the unit of milliseconds |

**Defaults** The default is 2,500 milliseconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Configuring the override-interval is to set the pruning veto time for the interface.

**Configuration** The following example sets the override-interval to 3,000 milliseconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim override-interval 3000
```

|                         |                |                    |

**Description**

## 5.7 ip pim propagation-delay

Use this command to reconfigure the propagation-interval of the hello message.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim propagation-delay** *interval-milliseconds*

**no ip pim propagation-delay**

**default ip pim propagation-delay**

| Parameter Description | Parameter                    | Description                                                                                         |
|-----------------------|------------------------------|-----------------------------------------------------------------------------------------------------|
|                       | <i>interval-milliseconds</i> | Propagation-interval of the hello message in the range from 1 to 32,767 in the unit of milliseconds |

**Defaults** The default is 500 milliseconds.

**Command Mode** Interface configuration mode

**Usage Guide** Configuring the propagation-delay is to set the transmission delay time for the interface.

**Configuration Examples** The following example sets the propagation-delay to 600 milliseconds.

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim propagation-delay 600
```

| Related Commands | Command | Description |

**Platform Description** N/A

## 5.8 ip pim query-interval

Use this command to reconfigure the interval of sending the hello message.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim query-interval** *interval-seconds*

**no ip pim query-interval**

**default ip pim query-interval**

| Parameter Description | Parameter               | Description                                                                                |
|-----------------------|-------------------------|--------------------------------------------------------------------------------------------|
|                       | <i>interval-seconds</i> | Interval of sending the hello message in the range from 1 to 65,535 in the unit of seconds |

**Defaults** The default is 30 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** If hello interval is set, the hello holdtime value will be updated to 3.5 times of hello interval.

**Configuration** The following example sets the interval of sending the hello message to 123 seconds.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastethernet 0/1
Ruijie(config-if)# ip pim query-interval 123
```

**Related Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform** N/A

**Description**

## 5.9 ip pim state-refresh disable

Use this command to prohibit the interface from processing and forwarding the PIM-DM state refresh messages.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim state-refresh disable**

**no ip pim state-refresh disable**

**default ip pim state-refresh disable**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** By default, the PIM-DM state refresh messages can be processed and forwarded.

**Command** Global configuration mode

**Mode**

**Usage Guide** When the state refresh function is disabled, the PIM-DM state refresh message is not processed and forwarded. The sent Hello message does not contain the status refresh option. Consequently, the SR Cap field will not be processed when the Hello message is received.

Generally, it is not recommended to disable the status refresh function because disabling this function may converge the PIM-DM multicast forwarding tree again that has been converged, resulting in unnecessary waste of bandwidth and oscillation of multicast routing table.

**Configuration** The following example disables the processing of the PIM-DM state refresh message.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip pim state-refresh disable
```

## 5.15 show ip pim dense-mode nexthop

Use this command to display the information about the PIM-DM next hop.

**show ip pim dense-mode nexthop**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the information about the PIM-Dm next hop:

```
Ruijie# show ip pim dense-mode nexthop
Destination  Nexthop  Nexthop  Nexthop  Metric  Pref
              Num      Addr      Interface
1.1.1.111    1        50.50.50.1  VLAN 4    0       1
```

| Field             | Description                             |
|-------------------|-----------------------------------------|
| Destination       | Multicast source IP address             |
| Nexthop Num       | Number of next hop                      |
| Nexthop Addr      | IP address of next hop                  |
| Nexthop interface | Interface connecting to the of next hop |
| Metric            | Route metric                            |
| Pref              | Route priority                          |

## 5.16 show ip pim dense-mode track

Use this command to display the statistics of the PIM-DM packets.

**show ip pim dense-mode track**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command is used to display the number of sent and received PIM packets during the period from the beginning of the statistics till now. When the system starts up, it sets the start time of the statistics. The start time of the statistics is reconfigured and the PIM packet counter is cleared on calling the clear ip pim dense-mode track every time.

**Configuration Examples** The following example displays the statistics of the PIM-DM packets.

```
Ruijie# show ip pim dense-mode track
          PIM packet counters
Elapsed time since counters cleared: 00:04:03
          received      sent
Valid PIMDM packets:      1          8
Hello:                    1          8
Join/Prune:                0          0
Graft:                     0          0
Graft-Ack:                 0          0
Assert:                    0          0
State-Refresh:            0          0
PIM-SM-Register:          0          0
PIM-SM-Register-Stop:     0          0
PIM-SM-BSM:               0          0
PIM-SM-C-RP-ADV:          0          0
Unknown Type:              0
Errors:
```

```
Malformed packets:      0
Bad checksums:          0
Unknown PIM version:    0
Send errors:            0
```

## 6 PIM-SM Commands

### 6.1 clear ip pim sparse-mode bsr rp-set \*

Use this command to clear all the RP information learnt dynamically.

**clear ip pim sparse-mode bsr rp-set \***

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** All the RP information learnt dynamically can be cleared manually.

**Configuration Examples** The following example clears all the RP information learnt dynamically.

```
Ruijie# clear ip pim sparse-mode bsr rp-set *
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 6.2 clear ip pim sparse-mode track

Use this command to reconfigure the start time of the statistics and clear the PIMv6 packet counter.

**clear ip pim sparse-mode track**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide**

**Configuration** The following example clears the PIM packet counter.

**Examples**

```
Ruijie# clear ip pim sparse-mode track
```

**Related Commands**

## 6.3 ip pim accept-bsr list

Use this command to confine the BSR address range.

Use the **no** or **default** form this command to restore the default setting.

**ip pim accept-bsr list** *access-list*

**no ip pim accept-bsr**

**default ip pim accept-bsr**

**Parameter Description**

| Parameter                      | Description                                                                 |
|--------------------------------|-----------------------------------------------------------------------------|
| <b>list</b> <i>access-list</i> | IP standard number ACL in the range of 1 to 99, 1300 to 1999 and characters |

**Defaults** By default, the PIMSM router receives all external BSM packets.

**Command** Global configuration mode

**Mode**

**Usage Guide** Use this command to limit the range of the legal BSR.

**Configuration** The following example confines the BSR address range.

**Examples**

```
Ruijie(config)# ip pim accept-bsr list 1
```

## 6.4 ip pim accept-crp list

Use this command to confine the C-RP address range and the multicast group address range it serves.

Use the **no** or **default** form of this command to restore the default setting,

**ip pim accept-crp list** *access-list*

**no ip pim accept-crp**

**default ip pim accept-crp**

| Parameter Description | Parameter                      | Description                                                                  |
|-----------------------|--------------------------------|------------------------------------------------------------------------------|
|                       | <b>list</b> <i>access-list</i> | IP extension number ACL in the range of 1 to 99, 1300 to 1999 and characters |

**Defaults** By default, the elected BSR receives all external advertisements of candidate RPs.

**Command** Global configuration mode

**Mode**

**Usage Guide** With this command configured on the candidate BSR, when this BSR becomes the elected BSR, it is able to limit the address range of the legal C-RP and the multicast group range it serves.

**Configuration Examples** The following example confines the C-RP address range and the multicast group address range it serves.

```
Ruijie (config)# ip pim accept-crp list 100
```

**Description**

## 6.5 ip pim accept-crp-with-null-group

Use this command to receive the C-RP-ADV packets whose prefix-count is 0.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim accept-crp-with-null-group**

**no ip pim accept-crp-with-null-group**

**default ip pim accept-crp-with-null-group**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|   |   |
|---|---|
| - | - |
|---|---|

**Defaults** By default, the BSR does not receive the C-RP-ADV packets whose prefix-count is 0.

**Command Mode** Global configuration mode

**Usage Guide** With this command configured on the candidate BSR, when this BSR becomes the elected BSR, it is able to receive the C-RP-ADV packets whose prefix-count is 0, and considers this C-RP supports all groups.

**Configuration** The following example receives the C-RP-ADV packets whose prefix-count is 0.

**Examples** Ruijie (config)# ip pim accept-crp-with-null-group

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 6.6 ip pim accept-register list

Use this command to confine the address range of the (S,G) entry of the register packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim accept-register** { **list** *access-list* [**route-map** *map-name*] | **route-map** *map-name* [**list** *access-list*] }

**no ip pim accept-register**

**default ip pim accept-register**

| Parameter Description            | Parameter                      | Description                                          |
|----------------------------------|--------------------------------|------------------------------------------------------|
|                                  | <b>list</b> <i>access-list</i> |                                                      |
| <b>route-map</b> <i>map-name</i> |                                | Uses a route map to define the (S, G) address range. |

**Defaults** The (S, G) address range is not confined by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to confine the source IP address of register messages on RP.

**Configuration** The following example confines the source address of register packets on the RP.

**Examples**

```
Ruijie (config)# ip pim accept-register list 100
Ruijie (config)# access-list 100 permit ip 192.168.195.0 0.0.0.255 225.1.1.1
0.0.0.255
```

## 6.7 ip pim bsr-border

Use this command to configure the BSR border.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim bsr-border**

**no ip pim bsr-border**

**default ip pim bsr-border**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

No BSR border is configured by default.

**Command  
Mode**

Interface configuration mode

**Usage Guide**

To restrain BSM flooding, configure BSR border on the interface so that the interface drops BSM packets upon receiving them and the BSM packets are not forwarded from this interface.

**Configuration** The following example sets the BSR border on the interface *g 0/3*

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if- GigabitEthernet 0/3)# ip pim bsr-border
```

## 6.8 ip pim bsr-candidate

Use this command to configure the C-BSR.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim bsr-candidate** *interface-type interface-number* [ *hash-mask-length* [ *priority-value* ] ]

**no ipv6 pim bsr-candidate**

**default ip pim bsr-candidate**

### Parameter Description

| Parameter                                        | Description                                                                                              |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | Interface type and number                                                                                |
| <i>hash-mask-length</i>                          | (Optional) HASK mask length configured for electing the RP in the range from 0 to 32, The default is 10. |
| <i>priority-value</i>                            | (Optional) Priority configured for the candidate BSR in the range from 0 to 255. The default is 64.      |

**Defaults** No C-BSR is configured by default.

**Command Mode** Global configuration mode

**Usage Guide** A PIM-SM domain must contain a unique Bootstrap Router (BSR). BSR is responsible for collect and issue RP information. A unique recognized BSR is elected among multiple candidate BSRs through the bootstrap packet. Before BSR information is available, C-BSRs consider them to be the BSR, and regularly send bootstrap packets using the multicast address 224.0.0.13 in the PIM-SM domain. This packet contains the address and priority of the BSR.

This command allows the device to send a bootstrap message to all the PIM neighbors using the assigned BSR address. Each neighbor compares the original BSR address with the address in the received bootstrap message. If the IP address of the received address is equal to or larger than the original address, each neighbor saves this received address as the BSR address. Otherwise, they will discard this message.

The current device considers itself to be BSR until it receives a bootstrap message from another candidate BSR and is notified that it has a higher priority value (or the same priority value, but with a larger IP address).

**Configuration** The following example configures the C-BSR.

**Examples**

```
Ruijie(config)# ip pim bsr-candidate gi 0/3 30 192
```

### Related Commands

**Description**

## 6.9 ip pim dr-priority

Use this command to set the DR priority.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim dr-priority** *priority-value*

**no ip pim dr-priority**

**default ip pim dr-priority**

| Parameter Description | Parameter             | Description                                                                             |
|-----------------------|-----------------------|-----------------------------------------------------------------------------------------|
|                       | <i>priority-value</i> | The larger the value, the higher the priority is. The range is from 0 to 4,294,967,294. |

**Defaults** The default is 1.

**Command** Interface configuration mode

**Mode**

**Usage Guide** To select a DR:

If the priority parameter of the Hello message is set for the devices in a LAN, the one of the highest priority is elected to be the DR. If several devices have the same priority, the one of the largest IP address is elected to be the DR.

If the priority parameter of the Hello message is not set for the devices in a LAN, the one of the largest IP address is elected to be the DR.

**Configuration** The following example sets the DR priority.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ip pim dr-priority 10000
```

## 6.12 ip pim neighbor-filter

Use this command to confine the neighbor address range.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim neighbor-filter** *access\_list*

**no ip pim neighbor-filter** *access\_list*

**default ip pim neighbor-filter** *access\_list*

**Parameter  
Description**

| Parameter          | Description                                                                    |
|--------------------|--------------------------------------------------------------------------------|
| <i>access_list</i> | Access control list supporting numerical ACL in the range 1 to 99 and name ACL |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Neighbor filtering can enhance the security of a PIM-enabled network and provide neighbor restriction. As long as a neighbor is denied by the access list, PIM-SM will not establish the peering relationship with this neighbor or terminate the established peering relationship with this neighbor.

**Configuration** The following example blocks the neighbor address 192.168.1.5.

**Examples** Ruijie(config)# interface gi 0/3  
Ruijie(config-if- GigabitEthernet 0/3)# ip pim neighbor-filter 14  
Ruijie(config-if- GigabitEthernet 0/3)# exit  
Ruijie(config)# access-list 14 deny 192.168.1.5 0.0.0.255

**Related  
Commands**

| Command            | Description |
|--------------------|-------------|
| <b>access-list</b> | N/A         |

**Platform** N/A

**Description**

## 6.13 ip pim neighbor-tracking

Use this command to disable join restraint on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim neighbor-tracking**

**no ip pim neighbor-tracking**

**default ip pim neighbor-tracking**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to disable join restraint on the interface. With join constraint enabled, the interface is constrained not to send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. On the other hand, with join constrain disabled, the interface will send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. This function allows upstream routers to track how many receivers in downstream in accord with all received Join messages.

**Configuration Examples** The following example disables join restraint on the interface.

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ip pim neighbor-tracking
```

| Related Commands | Command                         | Description |
|------------------|---------------------------------|-------------|
|                  | <b>ip pim propagation-delay</b> | N/A         |

**Platform Description** N/A

## 6.14 ip pim override-interval

Use this command to set the override-interval on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim override-interval *milliseconds***

**no ip pim override-interval**

**default ip pim override-interval**

| Parameter<br>Description | Parameter | Description                  |
|--------------------------|-----------|------------------------------|
|                          |           | <i>interval-milliseconds</i> |

**Defaults** The default is 2,500 milliseconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to set the override-interval for the interface.

 Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

**Configuration Examples** The following example sets the override-interval as 3000 milliseconds.

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ip pim override-interval 3000
```

| Related<br>Commands | Command | Description                     |
|---------------------|---------|---------------------------------|
|                     |         | <b>ip pim propagation-delay</b> |

**Platform Description** N/A

## 6.15 ip pim probe-interval

Use this command to set the register probe interval.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim probe-interval** *seconds*

**no ip pim probe-interval**

**default ip pim probe-interval**

| Parameter<br>Description | Parameter | Description             |
|--------------------------|-----------|-------------------------|
|                          |           | <i>interval-seconds</i> |

**Defaults** The default is 5 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to set the registration probe time. The DR can send the null registration message

to the RP in a period before the registration suppression time expires. This period is called probe time of null registration packet.

-  The probe time must be less than half of registration suppression time. Furthermore, 3\* registration suppression time plus registration probe time should be no more than 65535s or otherwise the system triggers an alarm.

**Configuration** The following example sets the probe time to 6 seconds.

**Examples**

```
Ruijie(config)# ip pim probe-interval 6
```

## 6.16 ip pim propagation-delay

Use this command to set the propagation-delay on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim propagation-delay** *milliseconds*

**no ip pim propagation-delay**

**default ip pim propagation-delay**

**Parameter  
Description**

| Parameter                    | Description                                |
|------------------------------|--------------------------------------------|
| <i>interval-milliseconds</i> | In the range from 1 to 32,765 milliseconds |

**Defaults** The default is 500 milliseconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Use this command to set the propagation-delay for the interface.

-  Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

**Configuration** The following example sets the propagation delay to 600 milliseconds.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config)# ip pim propagation-delay 600
```

**Description**

## 6.17 ip pim query-interval

Use this command to set the interval to send the hello packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim query-interval** *seconds*

**no ip pim query-interval**

**default ip pim query-interval**

| Parameter Description | Parameter | Description             |
|-----------------------|-----------|-------------------------|
|                       |           | <i>interval-seconds</i> |

**Defaults** The default is 30 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** Upon updating the interval to send the Hello message, the time of holding the Hello message is updated by the following principle: The hold time is updated to be 3.5 times the transmission interval. If the transmission interval\*3.5 is more than 65535, the hold time is updated to 18752.

**Configuration Examples** The following example sets the interval to send the hello packets to 123 seconds.

```
Ruijie(config)# interface gi 0/3
Ruijie(config)# ip pim query-interval 123
```

## 6.18 ip pim register-checksum-wholepkt

Use this command to calculate the checksum of the whole register packet.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-checksum-wholepkt [ group-list *access-list* ]**

**no ip pim register-checksum-wholepkt [ group-list *access-list* ]**

**default ip pim register-checksum-wholepkt [ group-list *access-list* ]**

| Parameter Description | Parameter          | Description                                                                                                                                                                                                          |
|-----------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>access-list</i> | Access-list: access control list supporting numerical ACL in the range from 100 to 199 and from 1300 to 1999 and name ACL.<br>Group-list <i>access-list</i> :all multicast packets use this configuration by default |

**Defaults** By default, the checksum of register messages calculates the head of PIM message and register message rather than the whole PIM message

**Command Mode** Global configuration mode

**Usage Guide** Some vendors calculate checksum based on the overall registration packets. Ruijie Networks introduces this function for the compatibility with devices of other vendors.

**Configuration** The following example calculates the checksum of the whole register packet.

**Examples**

```
Ruijie(config)#ip pim register-checksum-wholepkt group-list 99
Ruijie(config)# access-list 99 permit 225.1.1.1 0.0.0.255
```

**Description**

## 6.19 ip pim register-decapsulate-forward

Use this command to enable the RP to decapsulate the register packets and forward the multicast packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-decapsulate-forward**

**no ip pim register-decapsulate-forward**

**default ip pim register-decapsulate-forward**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to implement the decapsulate of the PIM-SM registration packets with the multicast data packets received on the candidate RP and forward the multicast data packets. As the decapsulating and forwarding are performed by the software, it is not recommended to configure this command in the case that many registration packets need to be decapsulated and forwarded, which may cause the CPU busy with this function configured.

**Configuration Examples** The following example enables the RP to decapsulate the register packets and forwards the multicast packets.

```
Ruijie(config)# ip pim register-decapsulate-forward
```

## 6.20 ip pim register-rate-limit

Use this command to limit the rate of register packets.

Use the **no** form of this command to restore the default setting.

**ip pim register-rate-limit rate**

**no ip pim register-rate-limit**

**default ip pim register-rate-limit**

| Parameter Description | Parameter   | Description                                                                                   |
|-----------------------|-------------|-----------------------------------------------------------------------------------------------|
|                       | -           | -                                                                                             |
|                       | <i>rate</i> | Maximum number of register packets that can be sent per second, in the range from 1 to 65,535 |

**Defaults** By default, there is no rate limitation on register messages.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to configure speed of transmitting register packet in each (S, G) status, not the speed of transmitting register packets in the system. Using this command will decrease the load of source DR and RP. The register packets can be transmitted at the speed within the limit.

**Configuration** The following example limits the rate of register packets.

**Examples**

```
Ruijie(config)# ip pim register-rate-limit 3000
```

## 6.21 ip pim register-rp-reachability

Use this command to check RP reachability before sending register packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-rp-reachability**

**no ip pim register-rp-reachability**

**default ip pim register-rp-reachability**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** By default, the RP reachability is not checked before sending register packets.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to check the RP reachability before sending register packets. If not, register packets are not transmitted.

**Configuration** The following example checks the RP reachability before sending register packets.

**Examples**

```
Ruijie(config)# ipv6 pim register-rp-reachability
```

| Related Commands | Command | Description |

## 6.22 ip pim register-source

Use this command to specify the source IP address of the register packets.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-source** { *local\_address* | *interface-type interface-number* }

**no ip pim register-source**

**default ip pim register-source**

| Parameter Description | Parameter                                        | Description                                                                     |
|-----------------------|--------------------------------------------------|---------------------------------------------------------------------------------|
|                       | -                                                | -                                                                               |
|                       | <i>interface-type</i><br><i>interface-number</i> | Interface whose IP address is used as the source IP address of register packets |
|                       | <i>local_address</i>                             | Specifies the source IP address of the register packet.                         |

**Defaults** By default, the source IP address of register packets is the IP address of the DR interface connecting the multicast source.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure the source IP address of register messages. The source IP address must be reachable. When RP receives the register packet, it transmits Register-Stop packet, using its source IP address as the destination IP address of the Register-Stop packet. It is not necessary to enable the PIM.

**Configuration** The following example specifies the source IP address of the register packets.

**Examples**

```
Ruijie(config)# ip pim register-source 192.168.195.80
Ruijie(config)# ip pim register-source gi 0/3
```

## 6.23 ip pim register-suppression

Use this command to set the register suppression time.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim register-suppression** *seconds*  
**no ip pim register-suppression**  
**default ip pim register-suppression**

| Parameter Description | Parameter          | Description                                                            |
|-----------------------|--------------------|------------------------------------------------------------------------|
|                       | <i>suppression</i> | Suppression time in the range from 1 to 65,535 in the unit of seconds. |

**Defaults** The default is 60 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Executing this command on the DR will change the register packet suppression time configured. if the **ip pim rp-register-kat** command is not configured, executing this command on RP will modify the period of RP keepalive.

**Configuration** The following example sets the register suppression time to 100 seconds.

**Examples** Ruijie(config)# ip pim register-suppression 100

| Related Commands | Command | Description |

## 6.24 ip pim rp-address

Use this command to configure the static RP.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim rp-address** *rp-address* [ *access\_list* ]  
**no ip pim rp-address** *rp-address* [ *access\_list* ]  
**default ip pim rp-address** *rp-address* [ *access\_list* ]

| Parameter Description | Parameter          | Description                                                                                                                                     |
|-----------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>rp-address</i>  | IP address of RP                                                                                                                                |
|                       | <i>access_list</i> | Access control list supporting numerical ACL in the range 1 to 99 and 1300 to 1999 and name ACL. All multicast groups are supported by default. |

**Defaults** No IP address is configured for the static RP by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** This system supports the configuration of multicast static RP, as well as the configuration of static RP and BSR mechanisms at the same time. When you use this command, note that:

If both the BSR mechanism and the static RP configuration take effect, the dynamic configuration takes precedence.

You can configure multiple multicast groups (using ACL) or all multicast groups (not using ACL) for the static RP. But a static RP can be configured only once.

If there are more than one static RP in a multicast group, the one of the highest IP address is used. Only the addresses permitted by ACL are valid multicast groups. By default, all the multicast groups 224/4 are permitted.

After configuration is performed, the static RP's source IP address is inserted to the group range-based static RP group tree structure. Each group range-based static multicast group maintains the chain list structure of a static RP group. This chain list is sorted in descending order of IP address. When you select a RP from a static RP group, the first entry, namely the one with the largest IP address, will be selected first.

Deleting a static IP address also deletes this address from all the existing static RP groups and selects one from in the existing RP group tree structure as the RP address.

**Configuration** The following example specifies the source IPv6 address of the register packet.

**Examples**

```
Ruijie(config)# ip pim rp-address 210.34.0.55 4
Ruijie(config)# access-list 4 permit 255.1.1.1 0.0.0.255
```

**Related

## 6.25 ip pim rp-candidate

Use this command to configure the C-RP.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim rp-candidate** *interface-type interface-number* [ **priority** *priority-value* ] [ **interval** *seconds* ]  
[ **group-list** *access\_list* ]

**no ip pim rp-candidate** [ *interface-type interface-number* ]

**default ip pim rp-candidate** [ *interface-type interface-number* ]

**Parameter  
Description**

| Parameter                                        | Description                         |
|--------------------------------------------------|-------------------------------------|
| <i>interface-type</i><br><i>interface-number</i> | Interface type and interface number |

|                       |                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------|
| <i>priority-value</i> | (Optional) Priority in the range 0 to 255, 192 by default                                                  |
| <i>seconds</i>        | (Optional) Interval in the range 0 to 16,383 seconds, 60s by default                                       |
| <i>access_list</i>    | (Optional) Numerical ACL in the range 1 to 99 or name ACL. By default, all multicast groups are permitted. |

**Defaults** No C-RP is configured by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** In the PIM-SM protocol, the shared tree RPT created by the multicast routing uses the Rendezvous Point (RP) as the root node. RP is elected by the candidate RPs. After BSR is elected, all C-RPs sends C-RP messages in the unicast form to BSR regularly, and BSR spreads the messages throughout the PIM domain.

To specify an interface as the candidate RP of a specific group, execute this command with ACL. Note that the group range is calculated only based on the permit rule, not the deny rule.

**Configuration** The following example configures the C-RP.

**Examples**

```
Ruijie(config)# ip pim rp-candidate gi 0/3 priority 200 group-list 3 interval 70
Ruijie(config)# access-list 3 permit 255.1.1.1 0.0.0.255
```

## 6.27 ip pim sparse-mode

Use this command to enable PIM-SM on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim sparse-mode**

**no ip pim sparse-mode**

**default ip pim sparse-mode**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** This command is used to enable PIM-SM on the interface.

-  You need to enable multicast routing forwarding in the global configuration mode before enabling PIM-SM. Otherwise, multicast packets cannot be forwarded even though you enable PIM-SM.
-  During the execution of this command, if the prompt "Failed to enable PIM-SM on <Interface Name>, resource temporarily unavailable, please try again" appears, re-execute this command.
-  During the execution of this command, if the prompt "PIM-SM Configure failed! VIF limit exceeded in NSM!!!" appears; it indicates the allowed configured interface number exceeds the upper limit of the multicast interfaces. In this case, if you still need to enable PIM-SM on the interface, delete the unnecessary PIM-SM, PIM-DM or DVMRP interfaces.
-  It is not recommended to configure different IPv4 multicast routing protocols on different

interfaces of a device.

**Configuration** The following example enables PIM-SM on the interface.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ip pim sparse-mode
```

## 6.28 ip pim sparse-mode passive

Use this command to enable PIM-SM PASSIVE.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim sparse-mode passive**

**no ip pim sparse -mode passive**

**default ip pim sparse-mode passive**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** PIM-SM PASSIVE is disabled by default.

**Command  
Mode** Interface configuration mode

**Usage Guide** Please configure multicast route forwarding in global configuration mode before enabling PIM-SM PASSIVE.  
When PIM-SM PASSIVE is enabled, IGMP is enabled on each interface automatically.  
Enabled with PIM-SM PASSIVE, the interface neither receives nor sends PIM packets. Instead, it forwards multicast packets. PIM-SM PASSIVE is generally configured on the device of the stub area, so as to avoid floods of PIM hello packets.

**Configuration** The following example enables PIM-SM PASSIVE on interface GigabitEthernet 0/3.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ip pim sparse-mode passive
```

**Description**

## 6.29 ip pim sparse-mode subvlan

Use this command to enable PIM-SM on the Super VLAN interface. Use the **no** or **default** form of this command is to restore the default setting.

**ip pim sparse-mode subvlan** [ **all** | *vid* ]

**no ip pim sparse-mode subvlan**

**default ip pim sparse-mode subvlan**

| Parameter          | Parameter  | Description                              |
|--------------------|------------|------------------------------------------|
| <b>Description</b> | <b>all</b> | Sends PIM packets to all sub VLANs.      |
|                    | <i>vid</i> | Sends PIM packets to the specified VLAN. |

**Defaults** PIM-SM is disabled on the Super VLAN interface by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** In general, a super VLAN includes many sub VLANs. If the PIM-SM protocol is enabled on the interfaces of the super VLAN, PIM-SM multicast packets will be replicated and sent to all sub VLANs. As a result, the traffic may exceed the device capability, causing protocol flapping. The Super VLAN interface is disabled with PIM-SM generally. Use this command to enable PIM-SM on the Super VLAN interface to send PIM packets to all sub VLANs or the specified sub VLAN.

**Configuration Examples** The following example enables PIM-SM on the Super VLAN interface and sends PIM packets to sub VLAN 200.

```
Ruijie# configure terminal
Ruijie(config)# interface vlan 100
Ruijie(config-if-vlan 100)# ip pim sparse-mode subvlan 200
```

## 6.30 ip pim spt-threshold

Use this command to enable the SPT switching function.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim spt-threshold [ group-list access-list ]**

**no ip pim spt-threshold [ group-list access-list ]**

**default ip pim spt-threshold [ group-list access-list ]**

| Parameter Description | Parameter          | Description                                                                                                                                   |
|-----------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>access_list</i> | (Optional) Numerical ACL in the range 1 to 99 and 1300 to 1999 or name ACL. By default, all multicast groups are permitted for SPT switching. |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to enable the RP tree-to-SPT tree switching function in a specific multicast group range (using **group-list**) or all multicast groups (not using **group-list**) .

**Configuration** The following example enables the SPT switching function.

**Examples**

```
Ruijie(config)# ip pim spt-threshold group-list 12
Ruijie(config)# access-list 12 permit 225.1.1.1 0.0.0.255
```

| Related Commands | Command            | Description |
|------------------|--------------------|-------------|
|                  | <b>access-list</b> | N/A         |

**Platform** N/A

**Description**

## 6.31 ip pim ssm

Use this command to enable SSM and set the SSM group address range.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim ssm { default / range access\_list }**

**no ip pim ssm**

**default ip pim ssm**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                                 |                                                                  |
|---------------------------------|------------------------------------------------------------------|
| <b>default</b>                  | Multicast groups of 232/8                                        |
| <b>range</b> <i>access_list</i> | Numerical ACL in the range 1 to 99 and 1300 to 1999 or name ACL. |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to enable PIM-SSM (or in some specific multicast groups).

**Configuration** The following command enables SSM and sets the SSM group range to 232/8:

**Examples** Ruijie(config)# ip pim ssm default

The following command sets the source-specific multicast with ACL 10.

Ruijie(config)# ip pim ssm range 10

Ruijie(config)# access-list 10 permit 232.0.0.1 0.0.0.255

**Description**

## 6.32 ip pim triggered-hello-delay

Use this command to configure Triggered-Hello-Delay time on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip pim triggered-hello-delay** *seconds*

**no ip pim triggered-hello-delay**

**default ip pim triggered-hello-delay**

**Parameter  
Description**

| Parameter      | Description                                      |
|----------------|--------------------------------------------------|
| <i>seconds</i> | In the range from 1 to 5 in the unit of seconds. |

**Defaults** The default is 5 seconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Use this command to configure the triggered-hello-delay of the interface. When the interface starts or detects a new neighbor, it uses the trigger-hello-delay to generate random time, and then the interface sends the Hello message in random time.

**Configuration** The following command sets the triggered-hello-delay to 3 seconds.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ip pim triggered-hello-delay 3
```

## 6.33 show debugging

Use this command to display the debugging status.

**show debugging**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide**

**Configuration** The following example displays the debugging status.

**Examples**

```
Ruijie#show debugging
ip packet debug:
ip packet debug debugging is on, acl: 0
```

## 6.34 show ip pim sparse-mode bsr-router

Use this command to display the BSR information

**show ip pim sparse-mode bsr-router**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

### Usage Guide

**Configuration** The following example displays BSR information.

**Examples**

```
Ruijie# show ip pim sparse-mode bsr-router
PIMv2 Bootstrap information
This system is the Bootstrap Router (BSR)
BSR address: 192.168.127.1
Uptime: 01d23h14m, BSR Priority: 64, Hash mask length: 10
Next bootstrap message in 00:00:42
Role: Candidate BSR Priority: 64, Hash mask length: 10
State: Elected BSR
Candidate RP: 30.30.100.200(GigabitEthernet 0/3)
Advertisement interval 60 seconds
00:00:32
```

## 6.35 show ip pim sparse-mode interface

Use this command to display PIM-SM interface information.

**show ip pim sparse-mode interface** [ *interface-type interface-number* ] [ **detail** ]

| Parameter Description | Parameter               | Description                                                                         |
|-----------------------|-------------------------|-------------------------------------------------------------------------------------|
|                       | <i>interface-type</i>   | (Optional) Interface name. This command takes effect for all interfaces by default. |
|                       | <i>interface-number</i> | (Optional) Displays the details of an interface.                                    |
|                       | <b>detail</b>           | (Optional) Displays the details of an interface.                                    |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

### Usage Guide

**Configuration** The following example displays the PIM-SM information on the interface.

```
Ruijie#show ip pim sparse-mode interface detail
GigabitEthernet 0/3 (vif 3):
Address 30.30.100.200, DR 30.30.100.200
Hello period 30 seconds, Next Hello in 11 seconds
Triggered Hello period 5 seconds
Neighbors:
2.2.2.2
```

## 6.36 show ip pim sparse-mode local-members

Use this command to display the local IGMP information on the PIM-SM interface.

**show ip pim sparse-mode local-members** [ *interface-type interface-number* ]

### Parameter Description

| Parameter               | Description                                                                         |
|-------------------------|-------------------------------------------------------------------------------------|
| <i>interface-type</i>   | (Optional) Interface name. This command takes effect for all interfaces by default. |
| <i>interface-number</i> |                                                                                     |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

### Usage Guide

**Configuration** The following example displays the local IGMP information on the PIM-SM interface.

```
Ruijie (config-if)#sh ip pim sparse-mode local-members
PIM Local membership information
GigabitEthernet 0/3:
(*, 225.1.1.1) : Include
```

```
Loopback 1:
GigabitEthernet 0/5:
```

## 6.37 show ip pim sparse-mode mroute

Use this command to display the PIM-SM routing information.

**show ip pim sparse-mode mroute** [ *group-or-source-address* [ *group-or-source-address* ] ]

**Parameter  
Description**

| Parameter                      | Description                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------------------|
| <i>group-or-source-address</i> | Group IP address or source IP address. Two addresses cannot both be the group addresses or the source addresses. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command is used to display routing information. Only one group IP address, one source IP address or one group IP address-source IP address pair can be configured at a time. You can also specify no group IP address or source IP address.

**Configuration Examples** The following example displays the PIM-SM routing information.

```
Ruijie#show ip pim sparse-mode mroute
```

**Description**

## 6.41 show ip pim sparse-mode rp-hash

Use this command to display the RP information corresponding to the group address.

**show ip pim sparse-mode rp-hash** *group-address*

| Parameter Description | Parameter            | Description                  |
|-----------------------|----------------------|------------------------------|
|                       | <i>group-address</i> | Group address to be resolved |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

### Usage Guide

**Configuration** The following example displays the RP information corresponding to the group address.

**Examples**

```
Ruijie# show ip pim sparse-mode rp-hash 255.1.1.1
RP: 30.30.100.1
Info source: 30.30.100.1, via bootstrap
```

**Platform** N/A

**Description**

## 6.42 show ip pim sparse-mode track

Use this command to display the number of sent and received PIM packets during the period from the beginning of the statistics till now.

**show ip pim sparse-mode track**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command is used to display the number of sent and received PIM packets during the period from the beginning of the statistics till now. When the system starts up, it sets the start time of the statistics. The start time of the statistics is reconfigured and the PIM packet counter is cleared on calling the **clear ip pim sparse-mode track** every time.

**Configuration Examples** The following example displays the number of sent and received PIM packets during the period from the beginning of the statistics till now.

```
Ruijie # show ip pim sparse-mode track
PIM packet counters track
Elapsed time since counters cleared: 00:04:03
received    sent
Valid PIMSM packets:      0          8
Hello:                    0          8
Join-Prune:                0          0
Register:                  0          0
Register-Stop:             0          0
Assert:                    0          0
BSM:                       0          0
C-RP-ADV:                  0          0
PIMDM-Graft:               0
PIMDM-Graft-Ack :         0
PIMDM-State-Refresh:      0
Unknown PIM Type:         0
Errors:
Malformed packets:                0
Bad checksums:                    0
Send errors:                       0
Packets received with unknown PIM version:  0
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  |         | N/A         |

**Platform Description** N/A

## 7 PIM-SMv6 Commands

### 7.1 clear ipv6 mroute

Use this command to clear multicast routing entries.

**clear ipv6 mroute** { \* | *ipv6\_group\_address* [ *ipv6\_source\_address* ] }

| Parameter Description | Parameter                  | Description                                                                          |
|-----------------------|----------------------------|--------------------------------------------------------------------------------------|
|                       | *                          | Deletes all the multicast routing entries.                                           |
|                       | <i>ipv6_group_address</i>  | Deletes the multicast routing entries of the specific group.                         |
|                       | <i>ipv6_source_address</i> | Deletes the multicast routing entries of the specific group and source IPv6 address. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example clears all the multicast routing entries.

```
Ruijie# clear ipv6 mroute *
```

The following example clears the multicast routing entries of the specified group.

```
Ruijie# clear ipv6 mroute ff66::6666
```

The following example clears the multicast routing entries of the specified group and source address.

```
Ruijie# clear ipv6 mroute ff66::6666 3333::3333
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 7.2 clear ipv6 mroute statistics

Use this command to delete the statistics of the multicast routing entries.

**clear ipv6 mroute statistics** { \* | *ipv6\_group\_address* [ *ipv6\_source\_address* ] }

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

| Description                |                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------|
| *                          | Deletes the statistics of all multicast routing entries.                                               |
| <i>ipv6_group_address</i>  | Deletes the statistics of the multicast routing entries of the specific group.                         |
| <i>ipv6_source_address</i> | Deletes the statistics of the multicast routing entries of the specific group and source IPv6 address. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example deletes the statistics of the multicast routing entries.

**Examples** Ruijie# `clear ipv6 mroute statistics *`

The following example clears the statistics of the multicast routing entries of the specified group.

Ruijie# `clear ipv6 mroute statistics ff66::6666`

The following example clears the statistics of the multicast routing entries of the specified group and source address.

Ruijie# `clear ipv6 mroute statistics ff66::6666 3333::3333`

**Description**

## 7.4 clear ipv6 pim sparse-mode track

Use this command to reconfigure the start time of the statistics and clear the PIMv6 packet counter.

**clear ipv6 pim sparse-mode track**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example clears the PIMv6 packet counter.

**Examples** Ruijie# clear ipv6 pim sparse-mode track

| Related Commands | Command                         | Description |
|------------------|---------------------------------|-------------|
|                  | show ipv6 pim sparse-mode track | N/A         |

**Platform** N/A

**Description**

## 7.5 ipv6 pim accept-bsr list

Use this command to confine the BSR address range.

Use the **no** or **default** form this command to restore the default setting.

**ipv6 pim accept-bsr list** *ipv6\_access-list*

**no ipv6 pim accept-bsr**

**default ipv6 pim accept-bsr**

| Parameter<br>Description | Parameter | Description                         |
|--------------------------|-----------|-------------------------------------|
|                          |           | <b>list</b> <i>ipv6_access-list</i> |

**Defaults** By default, the PIM-SMv6 router receives all external BSM packets.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example confines the BSR address range.

```
Ruijie(config)# ipv6 pim accept-bsr list bsr-list
```

## 7.6 ipv6 pim accept-crp list

Use this command to confine the C-RP address range and the multicast group address range it serves.

Use the **no** or **default** form of this command to restore the default setting,

**ipv6 pim accept-crp list** *ipv6\_access-list*

**no ipv6 pim accept-crp**

**default ipv6 pim accept-crp-with-null-group**

| Parameter<br>Description | Parameter | Description                         |
|--------------------------|-----------|-------------------------------------|
|                          |           | <b>list</b> <i>ipv6_access-list</i> |

**Defaults** No address is filtered by default.

**Command Mode** Global configuration mode

**Usage Guide** With this command configured on the candidate BSR, when this BSR becomes the elected BSR, it is able to limit the address range of the legal C-RP and the multicast group range it serves.

**Configuration** The following example confines the C-RP address range and the multicast group address range it serves.

**Examples**

```
Ruijie (config)# ipv6 pim accept-crp list crp-list
```

**Description**

## 7.7 ipv6 pim accept-crp-with-null-group

Use this command to receive the C-RP-ADV packets whose prefix-count is 0.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim accept-crp-with-null-group**

**no ipv6 pim accept-crp-with-null-group**

**default ipv6 pim accept-crp-with-null-group**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

This function is disabled by default.

**Command Mode**

Global configuration mode

**Usage Guide**

With this command configured on the candidate BSR, when this BSR becomes the elected BSR, it is able to receive the C-RP-ADV packets whose prefix-count is 0, and considers this C-RP supports all groups.

**Configuration** The following example receives the C-RP-ADV packets whose prefix-count is 0.

**Examples**

```
Ruijie (config)# ipv6 pim accept-crp-with-null-group
```

**Related Commands**

**Description**

## 7.8 ipv6 pim accept-register

Use this command to accept specific register packets at the RP.

Use the **no** or **default** form of this command to restore the default setting.

```
ipv6 pim accept-register { list ipv6_access-list [ route-map map-name ] | route-map map-name
[list ipv6_access-list ] }
```

```
no ipv6 pim accept-register
```

```
default ipv6 pim accept-register
```

| Parameter Description | Parameter                           | Description                   |
|-----------------------|-------------------------------------|-------------------------------|
|                       | <b>list</b> <i>ipv6_access-list</i> | IPv6 ACL supporting named ACL |
|                       | <b>route-map</b> <i>map-name</i>    | Defines the routing map rule  |

**Defaults** All register packets are received by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to confine the source IPv6 address of register messages on RP. If the unauthorized register source is received, the RP will return the Register-Stop message immediately.

**Configuration** The following example denies register packets of the specified source address at the RP.

**Examples**

```
Ruijie(config)# ipv6 pim accept-register list register-access-list
Ruijie(config)# ipv6 access-list register-access-list
Ruijie(config-ipv6-acl)# deny ipv6 fe80::2d0:f8ff:fe22:33ad/128 any
```

**Platform** N/A

**Description**

## 7.9 ipv6 pim bsr-border

Use this command to configure the BSR border.

Use the **no** or **default** form of this command to restore the default setting.

```
ipv6 pim bsr-border
```

```
no ipv6 pim bsr-border
```

```
default ipv6 pim bsr-border
```

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** No BSR border is configured by default.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** To restrain BSM flooding, configure BSR border on the interface so that the interface drops BSM packets upon receiving them and the BSM packets are not forwarded from this interface.

**Configuration** The following example sets the BSR border on the interface *gi 0/3*.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet)# ipv6 pim bsr-border
```

| Related Commands | Command | Description |

**Description**

## 7.10 ipv6 pim bsr-candidate

Use this command to configure the candidate bootstrap router (C-BSR).

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim bsr-candidate** *interface-type interface-number* [ *hash-mask-length* [ *priority-value* ] ]

**no ipv6 pim bsr-candidate**

**default ipv6 pim bsr-candidate**

| Parameter Description   | Parameter                                        | Description                                                                                                |
|-------------------------|--------------------------------------------------|------------------------------------------------------------------------------------------------------------|
|                         | <i>interface-type</i><br><i>interface-number</i> |                                                                                                            |
| <i>hash-mask-length</i> |                                                  | (Optional) HASK mask length configured for electing the RP in the range from 0 to 128. The default is 126. |
| <i>priority-value</i>   |                                                  | (Optional) Priority configured for the C-BSR in the range from 0 to 255. The default is 64.                |

**Defaults** No C-BSR is configured by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** A PIM-SMv6 domain must contain a unique Bootstrap Router (BSR). BSR is responsible for collect and issue RP information. A unique recognized BSR is elected among multiple candidate BSRs through the bootstrap packet. Before BSR information is available, C-BSRs consider them to be the BSR, and regularly send bootstrap packets using the multicast address 224.0.0.13 in the PIM-SM

domain. This packet contains the address and priority of the BSR.

This command allows the device to send a bootstrap message to all the PIM neighbors using the assigned BSR address. Each neighbor compares the original BSR address with the address in the received bootstrap message. If the IPv6 address of the received address is equal to or larger than the original address, each neighbor saves this received address as the BSR address. Otherwise, they will discard this message.

The current device considers itself to be BSR until it receives a bootstrap message from another candidate BSR and is notified that it has a higher priority value (or the same priority value, but with a larger IPv6 address).

**Configuration** The following example s configures the C-BSR.

**Examples** Ruijie(config)# ipv6 pim bsr-candidate gi 0/3 30 100

**Description**

## 7.11 ipv6 pim dr-priority

Use this command to configure the DR priority.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim dr-priority** *priority-value*

**no ipv6 pim dr-priority**

**default ipv6 pim dr-priority**

**Parameter  
Description**

| Parameter             | Description                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------|
| <i>priority-value</i> | The larger the value, the higher the priority is. The range is from 0 to 4,294,967,294. The default is 1. |

**Defaults** The default is 1.

**Command  
Mode** Interface configuration mode

**Usage Guide** To select a DR:

- If the priority parameter of the Hello message is set for the devices in a LAN, the one of the highest priority is elected to be the DR. If several devices have the same priority, the one of the largest IP address is elected to be the DR.
- If the priority parameter of the Hello message is not set for the devices in a LAN, the one of the largest IP address is elected to be the DR.

**Configuration** The following example configures the DR priority.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if)# ipv6 pim dr-priority 11234
```

## 7.13 ipv6 pim jp-timer

Use this command to set the interval to send the join/prune message.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim jp-timer** *seconds*

**no ipv6 pim jp-timer**

**default ipv6 pim jp-timer**

| Parameter Description | Parameter      | Description                                                                                  |
|-----------------------|----------------|----------------------------------------------------------------------------------------------|
|                       | <i>seconds</i> | Interval to send the join/prune message in the range from 1 to 65,535 in the unit of seconds |

**Defaults** The default is 60 seconds.

**Command Mode** Global configuration mode

### Usage Guide

**Configuration Examples** The following example sets the interval to send the Join/Prune message to 100 seconds.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim jp-timer 100
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 7.14 ipv6 pim neighbor-filter

Use this command to confine the neighbor address range.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim neighbor-filter** *ipv6\_access-list*

**no ipv6 pim neighbor-filter** *ipv6\_access-list*

**default ipv6 pim neighbor-filter** *ipv6\_access-list*

| Parameter Description | Parameter               | Description                   |
|-----------------------|-------------------------|-------------------------------|
|                       | <i>ipv6_access_list</i> | IPv6 ACL supporting named ACL |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Neighbor filtering can enhance the security of a PIM-enabled network and provide neighbor restriction. As long as a neighbor is denied by the access list, PIM-SM will not establish the peering relationship with this neighbor or terminate the established peering relationship with this neighbor.

**Configuration Examples** The following example blocks the neighbor address fe80::2d0:f8ff:fe22:33ad.

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if- GigabitEthernet 0/3)# ipv6 pim neighbor-filter acl
Ruijie(config-if- GigabitEthernet 0/3)# exit
Ruijie(config)# ipv6 access-list acl
Ruijie(config-ipv6-acl)# deny ipv6 fe80::2d0:f8ff:fe22:33ad/128 any
```

**Related Commands**

| Command          | Description |
|------------------|-------------|
| ipv6_access-list | N/A         |

**Platform Description** N/A

## 7.15 ipv6 pim neighbor-tracking

Use this command to disable join restraint on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim neighbor-tracking**

**no ipv6 pim neighbor-tracking**

**default ipv6 pim neighbor-tracking**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to disable join restraint on the interface. With join constraint enabled, the interface is constrained not to send its Join message to the upstream neighbor when it receives the Join message that its neighbor sends to the upstream neighbor. On the other hand, with join constrain disabled, the interface will send its Join message to the upstream neighbor when it receives the Join

message that its neighbor sends to the upstream neighbor. This function allows upstream routers to track how many receivers in downstream in accord with all received Join messages.

**Configuration** The following example disables join restraint on the interface.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet)# ipv6 pim neighbor-tracking
```

**Related  
Commands**

| Command                           | Description |
|-----------------------------------|-------------|
| <b>ipv6 pim propagation-delay</b> | N/A         |

**Platform** N/A

**Description**

## 7.16 ipv6 pim override-interval

Use this command to set the override-interval on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim override-interval** *milliseconds*

**no ipv6 pim override-interval**

**default ipv6 pim override-interval**

**Parameter  
Description**

| Parameter           | Description                                          |
|---------------------|------------------------------------------------------|
| <i>milliseconds</i> | In the range 1 to 65,535 in the unit of milliseconds |

**Defaults** The default is 2,500 milliseconds.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Use this command to set the override-interval for the interface.

 Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

**Configuration** The following example sets the override-interval to 3,000 milliseconds.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet)# ipv6 pim override-interval 3000
```

**Related  
Commands**

| Command                           | Description |

| <b>ipv6 pim propagation-delay</b> | N/A         |

**Platform** N/A

**Description**

## 7.17 ipv6 pim probe-interval

Use this command to set the register probe interval.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim probe-interval** *seconds*

**no ipv6 pim probe-interval**

**default ipv6 pim probe-interval**

| Parameter Description | Parameter      | Description                                          |
|-----------------------|----------------|------------------------------------------------------|
|                       | <i>seconds</i> | In the range from 1 to 65,535 in the unit of seconds |

**Defaults** The default is 5 seconds.

**Command** Global configuration mode

**Mode**

**Usage Guide** Use this command to set the registration probe time. The DR can send the null registration message to the RP in a period before the registration suppression time expires. This period is called probe time of null registration packet.

-  The probe time must be less than half of registration suppression time. Furthermore, 3\* registration suppression time plus registration probe time should be no more than 65535s or otherwise the system triggers an alarm.

**Configuration** The following example sets the probe time as 6 seconds.

**Examples** Ruijie(config)# ipv6 pim probe-interval 6

| Related Commands | Command                              | Description |
|------------------|--------------------------------------|-------------|
|                  | <b>ipv6 pim register-suppression</b> | N/A         |

**Platform** N/A

**Description**

## 7.18 ipv6 pim propagation-delay

Use this command to set the propagation-delay on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim propagation-delay** *milliseconds*  
**no ipv6 pim propagation-delay**  
**default ipv6 pim propagation-delay**

| Parameter<br>Description | Parameter           | Description                                               |
|--------------------------|---------------------|-----------------------------------------------------------|
|                          | <i>milliseconds</i> | In the range from 1 to 32,765 in the unit of milliseconds |

**Defaults** The default is 500 milliseconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to set the propagation-delay for the interface.

 Change of propagation delay or prune delay will influence the override interval of Join/prune message. As specified in the protocol, the override interval of Join/prune message must be less than its hold time or otherwise this will cause temporary interruption.

**Configuration Examples** The following example sets the propagation delay to 600 milliseconds.

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ipv6 pim propagation-delay 600
```

| Related<br>Commands | Command                           | Description |
|---------------------|-----------------------------------|-------------|
|                     | <b>ipv6 pim override-interval</b> | N/A         |
|                     | <b>ipv6 pim neighbor-tracking</b> | N/A         |

**Platform Description** N/A

## 7.19 ipv6 pim query-interval

Use this command to set the interval to send the hello packets.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim query-interval** *seconds*  
**no ipv6 pim query-interval**  
**default ipv6 pim query-interval**

| Parameter<br>Description | Parameter      | Description                                                                             |
|--------------------------|----------------|-----------------------------------------------------------------------------------------|
|                          | <i>seconds</i> | Interval to send the Hello message in the range from 1 to 65,535 in the unit of seconds |

**Defaults** The default is 30.

**Command Mode** Interface configuration mode

**Usage Guide** Upon updating the interval to send the Hello message, the time of holding the Hello message is updated by the following principle: The hold time is updated to be 3.5 times the transmission interval. If the transmission interval\*3.5 is more than 65535, the hold time is updated to 18725.

**Configuration Examples** The following example sets the interval to send the hello packets.

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ipv6 pim query-interval 60
```

**Related Commands**

## 7.20 ipv6 pim register-checksum-wholepkt

Use this command to calculate the checksum of the whole register packet.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-checksum-wholepkt [ group-list *ipv6\_access-list* ]**

**no ipv6 pim register-checksum-wholepkt [ group-list *ipv6\_access-list* ]**

**default ipv6 pim register-checksum-wholepkt [ group-list *ipv6\_access-list* ]**

**Parameter Description**

| Parameter                                 | Description                                                                                                        |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>group-list <i>ipv6_access-list</i></b> | IPv6 ACL supporting named ACL.<br><i>ipv6_access-list</i> :all multicast packets use this configuration by default |

**Defaults** By default, the checksum of register messages calculates the head of PIM message and register message rather than the whole PIM message.

**Command Mode** Global configuration mode

**Usage Guide** Some vendors calculate checksum based on the overall registration packets. Ruijie Networks introduces this function for the compatibility with these vendors.

**Configuration Examples** The following example calculates the checksum of the whole register packet.

```
Ruijie(config)#ipv6 pim register-checksum-wholepkt group-list
```

```
checksum-access-list
Ruijie(config)# ipv6 access-list 99 checksum-access-list
Ruijie(config-ipv6-acl)# permit ipv6 any ff66::6666/64
```

**Related

## 7.21 ipv6 pim register-rate-limit

Use this command to limit the rate of register packets.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-rate-limit** *rate*

**no ipv6 pim register-rate-limit**

**default ipv6 pim register-rate-limit**

**Parameter  
Description**

| Parameter   | Description                                                                                    |
|-------------|------------------------------------------------------------------------------------------------|
| <i>rate</i> | Maximum number of register packets that can be sent per second, in the range from 1 to 65,535. |

**Defaults** By default, there is no rate limitation on register messages.

**Command  
Mode** Global configuration mode

**Usage Guide** This command is used to configure speed of transmitting register packet in each (S, G) status, not the speed of transmitting register packets in the system. Using this command will decrease the load of source DR and RP. The register packets can be transmitted at the speed within the limit.

**Configuration** The following example limits the rate of register packets.

**Examples** Ruijie(config)# ipv6 pim register-rate-limit 3000

**Related  
Commands**

## 7.22 ipv6 pim register-rp-reachability

Use this command to check RP reachability before sending register packets.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-rp-reachability**

**no ipv6 pim register-rp-reachability**

**default ipv6 pim register-rp-reachability**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** By default, the RP reachability is not checked before sending register packets.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to check the RP reachability before transmission. If not, register packets are not transmitted.

**Configuration Examples** The following example checks the RP reachability before sending register packets.

```
Ruijie(config)# ipv6 pim register-rp-reachability
```

| Related Commands | Command | Description |

## 7.23 ipv6 pim register-source

Use this command to specify the source IPv6 address in the register packets.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-source** { *ipv6\_local\_address* | *interface-type interface-number* }

**no ipv6 pim register-source**

**default ipv6 pim register-source**

| Parameter Description | Parameter                                        | Description                                                                         |
|-----------------------|--------------------------------------------------|-------------------------------------------------------------------------------------|
|                       | <i>ipv6_local_address</i>                        | Source IPv6 address of register packets                                             |
|                       | <i>interface-type</i><br><i>interface-number</i> | Interface whose IPv6 address is used as the source IPv6 address of register packets |

**Defaults** By default, the source IPv6 address of register packets is the IPv6 address of the DR interface connecting the multicast source.

**Command Mode** Global configuration mode

**Usage Guide** The source IPv6 address must be reachable. When RP receives the register packet, it transmits Register-Stop packet, using its source IPv6 address as the destination IPv6 address of the Register-Stop packet.

 It is not necessary to enable the PIM-SMv6 on the associated interfaces.

**Configuration Examples** The following example configures the source IPv6 address of register messages.

```
Ruijie(config)# ipv6 pim register-source 3333::3333
Ruijie(config)# ipv6 pim register-source gi 0/3
```

## 7.24 ipv6 pim register-suppression

Use this command to set the register suppression time.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim register-suppression** *seconds*

**no ipv6 pim register-suppression**

**default ipv6 pim register-suppression**

**Parameter Description**

| Parameter      | Description                                                           |
|----------------|-----------------------------------------------------------------------|
| <i>seconds</i> | Suppression time in the range from 1 to 65,535 in the unit of seconds |

**Defaults** The default is 60 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Executing this command on the DR will change the register packet suppression time configured. if the ipv6 pim rp-register-kat command is not configured, executing this command on RP will modify the period of RP keepalive.

**Configuration** The following example sets the register packet suppression time.

**Examples**

```
Ruijie(config)# ipv6 pim register-suppression 100
```

**Description**

## 7.25 ipv6 pim rp embedded

Use this command to enable the embedded RP function.

Use the **no** or **default** form of this command to disable this function.

**ipv6 pim rp embedded [ group-list *ipv6\_acl\_name* ]**

**no ipv6 pim rp embedded**

**default ipv6 pim rp embedded**

| Parameter Description | Parameter                              | Description |
|-----------------------|----------------------------------------|-------------|
|                       | <b>group-list <i>ipv6_acl_name</i></b> | IPv6 ACL    |

**Defaults** This function is enabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to enable the embedded RP function explicitly and to enable the embedded RP for the IPv6 multicast address of specified embedded RP address.

**Configuration Examples** The following example enables the embedded RP for the IPv6 multicast addresses of all embedded RP addresses.

```
Ruijie(config)# ipv6 pim rp embedded
```

| Related Commands | Command                 | Description |
|------------------|-------------------------|-------------|
|                  | <b>ipv6 access-list</b> | N/A         |

**Description**

## 7.26 ipv6 pim rp-address

Use this command to configure the static RP.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim rp-address** *ipv6\_rp-address* [ *ipv6\_access\_list* ]

**no ipv6 pim rp-address** *ipv6\_rp-address* [ *ipv6\_access-list* ]

**default ipv6 pim rp-address** *ipv6\_rp-address* [ *ipv6\_access-list* ]

| Parameter Description | Parameter               | Description                   |
|-----------------------|-------------------------|-------------------------------|
|                       | <i>ipv6_rp-address</i>  | IPv6 address of RP            |
|                       | <i>ipv6_access_list</i> | IPv6 ACL supporting named ACL |

**Defaults** No IPv6 address is configured for the static RP by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This system supports the configuration of multicast static RP, as well as the configuration of static RP and BSR mechanisms at the same time. When you use this command, note that:

- If both the BSR mechanism and the static RP configuration take effect, the dynamic configuration takes precedence.
- You can configure multiple multicast groups (using ACL) or all multicast groups (not using ACL) for the static RP. But a static RP can be configured only once.
- If there are more than one static RP in a multicast group, the one of the highest IPv6 address is used.
- Only the addresses permitted by ACL are valid multicast groups. By default, all the multicast groups 224/4 are permitted.
- After configuration is performed, the static RP's source IPv6 address is inserted to the group range-based static RP group tree structure. Each group range-based static multicast group maintains the chain list structure of a static RP group. This chain list is sorted in descending order of IPv6 address. When you select a RP from a static RP group, the first entry, namely the one with the largest IPv6 address, will be selected first.

Deleting a static IPv6 address also deletes this address from all the existing static RP groups and selects one from in the existing RP group tree structure as the RP address.

**Configuration** The following example configures the RP static address.

**Examples**

```
Ruijie(config)# ipv6 pim rp-address 3333::3333 acl
Ruijie(config)# ipv6 access-list acl
Ruijie(config)# permit ipv6 any ff66::6666/64
```

**Description**

## 7.27 ipv6 pim rp-candidate

Use this command to configure the candidate RP (C-RP).

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim rp-candidate** *interface-type interface-number* [ **priority** *priority-value* ] [ **interval** *interval-seconds* ] [ **group-list** *ipv6\_access-list* ]

**no ipv6 pim rp-candidate** [ *interface-type interface-number* ]

**default ipv6 pim rp-candidate** [ *interface-type interface-number* ]

| Parameter Description | Parameter                                        | Description                                                                            |
|-----------------------|--------------------------------------------------|----------------------------------------------------------------------------------------|
|                       | <i>interface-type</i><br><i>interface-number</i> | Interface type and interface number                                                    |
|                       | <i>priority-value</i>                            | (Optional) Priority in the range from 0 to 255, 192 by default                         |
|                       | <i>interval-seconds</i>                          | (Optional) Interval in the range from 0 to 16383 in the unit of seconds, 60 by default |
|                       | <i>ipv6_access_list</i>                          | (Optional) IPv6 ACL supporting named ACL                                               |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** In the PIM-SMv6 protocol, the shared tree RPT created by the multicast routing uses the Rendezvous Point (RP) as the root node. RP is elected by the candidate RPs. After BSR is elected, all C-RPs sends C-RP messages in the unicast form to BSR regularly, and BSR spreads the messages throughout the PIM domain.

To specify an interface as the candidate RP of a specific group, execute this command with ACL.

Note that the group range is calculated only based on the permit rule, not the deny rule.

**Configuration** The following example configures the RP candidate.

```
Ruijie(config)# ipv6 pim rp-candidate gi 0/3 priority 200 group-list acl
interval 40
Ruijie(config)# ipv6 access-list acl
Ruijie(config-ipv6-acl)# permit ipv6 any ff66::6666/64
```

**Platform** N/A  
**Description**

## 7.28 ipv6 pim rp-register-kat

Use this command to set the Keepalive Timer (KAT) of a (S, G) entry created by the register packet at the RP.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim rp-register-kat** *seconds*

**no ipv6 pim rp-register-kat**

**default ipv6 pim rp-register-kat**

| Parameter   | Parameter      | Description                                                     |
|-------------|----------------|-----------------------------------------------------------------|
| Description | <i>seconds</i> | KAT value in the range from 1 to 65,525 in the unit of seconds. |

**Defaults** The default is equal to the sum of register probe time and three times register suppression time.

**Command** Global configuration mode  
**Mode**

**Usage Guide** The KAT value at the RP should be greater than three times the register suppression time at the source DR. Otherwise, the KAT will end and the entry (S,G) will time out before another register packet is sent, so that multicast stream will break down in a short while.

**Configuration** The following example configures the KAT interval of RP.

**Examples** Ruijie(config)# `ipv6 pim rp-register-kat 250`

| Related Commands | Command | Description |
|------------------|---------|-------------|

**Platform** N/A  
**Description**

## 7.29 ipv6 pim sparse-mode

Use this command to enable PIM-SMv6 on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim sparse-mode**

**no ipv6 pim sparse-mode**

**default ipv6 pim sparse-mode**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command is used to enable PIM-SMv6 on the interface.

-  You need to enable multicast routing forwarding in the global configuration mode before enabling PIM-SMv6. Otherwise, multicast packets cannot be forwarded even though you enable PIM-SM.
-  During the execution of this command, if the prompt "Failed to enable PIM-SMv6 on <Interface Name>, resource temporarily unavailable, please try again" appears, re-execute this command.
-  During the execution of this command, if the prompt "PIM-SMv6 Configure failed! VIF limit exceeded in NSM!!!" appears; it indicates the allowed configured interface number exceeds the upper limit of the multicast interfaces. In this case, if you still need to enable PIM-SMv6 on the interface, delete the unnecessary PIM-SMv6, or PIM-DMv6 interfaces.
-  IPv6 multicast packets cannot be forwarded through SuperVLAN.

**Configuration** The following example enables PIM-SMv6 on the interface.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ipv6 pim sparse-mode
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     |         | N/A         |

## 7.30 ipv6 pim sparse-mode passive

Use this command to enable PIM-SMv6 PASSIVE.

Use the no or default form of this command to restore the default setting.

**ipv6 pim sparse-mode passive**

**no ipv6 pim sparse -mode passive**

**default ipv6 pim sparse-mode passive**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           |             |

|     |     |
|-----|-----|
| N/A | N/A |
|-----|-----|

**Defaults** PIM-SMv6 PASSIVE is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Please configure multicast route forwarding in global configuration mode before enabling PIM-SMv6 PASSIVE.  
When PIM-SMv6 PASSIVE is enabled, IGMP is enabled on each interface automatically.  
Enabled with PIM-SMv6 PASSIVE, the interface neither receives nor sends PIM packets. Instead, it forwards multicast packets. PIM-SMv6 PASSIVE is generally configured on the device of the stub area, so as to avoid floods of PIM hello packets.

**Configuration Examples** The following example enables PIM-SMv6 PASSIVE on interface GigabitEthernet 0/3.

```
Ruijie# configure terminal
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ipv6 pim sparse-mode passive
```

**Platform Description** N/A

## 7.31 ipv6 pim sparse-mode subvlan

Use this command to enable PIM-SMv6 on the Super VLAN interface. Use the **no** or **default** form of this command is to restore the default setting.

**ipv6 pim sparse-mode subvlan [ all | vid ]**

**no ipv6 pim sparse-mode subvlan**

**default ipv6 pim sparse-mode subvlan**

| Parameter          | Parameter  | Description                              |
|--------------------|------------|------------------------------------------|
| <b>Description</b> | <b>all</b> | Sends PIM packets to all sub VLANs.      |
|                    | <b>vid</b> | Sends PIM packets to the specified VLAN. |

**Defaults** PIM-SMv6 is disabled on the Super VLAN interface by default.

**Command Mode** Interface configuration mode

**Usage Guide** In general, a super VLAN includes many sub VLANs. If the PIM-SMv6 protocol is enabled on the

interfaces of the super VLAN, PIM-SMv6 multicast packets will be replicated and sent to all sub VLANs. As a result, the traffic may exceed the device capability, causing protocol flapping. The Super VLAN interface is disabled with PIM-SMv6 generally. Use this command to enable PIM-SMv6 on the Super VLAN interface to send PIM packets to all sub VLANs or the specified sub VLAN.

**Configuration Examples** The following example enables PIM-SMv6 on the Super VLAN interface and sends PIM packets to sub VLAN 200.

```
Ruijie# configure terminal
Ruijie(config)# interface vlan 100
Ruijie(config-if-vlan 100)# ipv6 pim sparse-mode subvlan 200
```

## 7.32 ipv6 pim spt-threshold

Use this command to enable SPT switch.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim spt-threshold** [group-list *ipv6\_access-list*]

**no ipv6 pim spt-threshold** [ group-list *ipv6\_access-list* ]

**default ipv6 pim spt-threshold** [ group-list *ipv6\_access-list* ]

**Parameter Description**

| Parameter               | Description                              |
|-------------------------|------------------------------------------|
| <i>ipv6_access_list</i> | (Optional) IPv6 ACL supporting named ACL |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to enable the RP tree-to-SPT tree switching function in a specific multicast group range (using group-list) or all multicast groups (not using group-list) .

**Configuration Examples** The following example enables the SPT switch.

```
Ruijie(config)# ipv6 pim spt-threshold acl
Ruijie(config)# ipv6 access-list acl
Ruijie(config-ipv6-acl)# permit ipv6 fe80::2d0:f8ff:fe22:33ad /128
ff66::6666/64
```

Description

## 7.33 ipv6 pim ssm

Use this command to enable SSM and set the SSM group address range.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim ssm** { **default** / **range** *ipv6\_access-list* }

**no ipv6 pim ssm**

**default ipv6 pim ssm**

| Parameter Description                | Parameter      | Description                   |
|--------------------------------------|----------------|-------------------------------|
|                                      | <b>default</b> |                               |
| <b>range</b> <i>ipv6_access_list</i> |                | IPv6 ACL supporting named ACL |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to enable PIM-SSMv6 (or in some specific multicast groups).

**Configuration** The following example sets the source-specific multicast of the multicast group range ACL.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 pim ssm range acl
Ruijie(config-ipv6-acl)# permit ipv6 fe80::2d0:f8ff:fe22:33ad /128 ff32::3333/64
```

Description

## 7.34 ipv6 pim static-rp-preferred

Use this command to configure a higher priority for static RP over the C-RP.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim static-rp-preferred**  
**no ipv6 pim static-rp-preferred**  
**default ipv6 pim static-rp-preferred**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** By default, the priority of the RP elected through BSR mechanism is high than the one configured statically.

**Command Mode** Global configuration mode

**Usage Guide** With this command configured, the priority of the static RP is higher than the one elected through the BSR mechanism.

**Configuration Examples** The following example configures the priority of the static RP is higher than the one elected through the BSR mechanism.

```
Ruijie(config-if)# ipv6 pim static-rp-preferred
```

| Related Commands | Command | Description |

## 7.35 ipv6 pim triggered-hello-delay

Use this command to configure Triggered-Hello-Delay time on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 pim triggered-hello-delay** *seconds*  
**no ipv6 pim triggered-hello-delay**  
**default ipv6 pim triggered-hello-delay**

| Parameter Description | Parameter      | Description                                      |
|-----------------------|----------------|--------------------------------------------------|
|                       | <i>seconds</i> | In the range from 1 to 5 in the unit of seconds. |

**Defaults** The default is 5 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to configure the triggered-hello-delay of the interface. When the interface starts or detects a new neighbor, it uses the trigger-hello-delay to generate random time, and then the interface sends the Hello message at the random time.

**Configuration** The following example sets the triggered-hello-delay to 3 seconds.

**Examples**

```
Ruijie(config)# interface gi 0/3
Ruijie(config-if-GigabitEthernet 0/3)# ipv6 pim triggered-hello-delay 3
```

### 7.39 show ipv6 pim sparse-mode local-members

Use this command to display the local MLD information on the PIM-SMv6 interface.

**show ipv6 pim sparse-mode local-members** [ *interface-type interface-number* ]

| Parameter Description | Parameter                                        | Description                                                                         |
|-----------------------|--------------------------------------------------|-------------------------------------------------------------------------------------|
|                       | <i>interface-type</i><br><i>interface-number</i> | (Optional) Interface name. This command takes effect for all interfaces by default. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the local MLD information on the PIM-SMv6 interface.

**Examples**

```
Ruijie (config-if)#show ipv6 pim sparse-mode local-members
PIM Local membership information
GigabitEthernet 0/5:
  (*, ff66::6666) : Include
```

## 7.40 show ipv6 pim sparse-mode mroute

Use this command to display the PIM-SMv6 routing information.

**show ipv6 pim sparse-mode mroute** [ *group-or-source-address* [ *group-or-source-address* ] ]

**Parameter  
Description**

| Parameter                      | Description                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------|
| <i>group-or-source-address</i> | Group address or source address. Two addresses cannot both be the group addresses or the source addresses. |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command is used to display route information. Only one group IPv6 address, one source IPv6 address or one group IPv6 address-source IPv6 address pair can be configured at a time. You can also specify no group IP address or source IPv6 address.

**Configuration** N/A

## 7.41 show ipv6 pim sparse-mode neighbor

Use this command to display the neighbor information.

**show ipv6 pim sparse-mode neighbor [ detail ]**

| Parameter Description | Parameter     | Description                                      |
|-----------------------|---------------|--------------------------------------------------|
|                       | <b>detail</b> | (Optional) Displays the details of an interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

### Usage Guide

**Configuration** The following example displays the neighbor information..

### Examples

```
Ruijie# show ipv6 pim sparse-mode neighbor detail
Nbr fe80::2d0:f8ff:fe22:34b3 (GigabitEthernet 0/5)
Expires in 86 seconds
Secondary addresses:
6666::6666
```

## 7.43 show ipv6 pim sparse-mode rp mapping

Use this command to display the information on all RPs and the multicast groups they serve.

**show ipv6 pim sparse-mode rp mapping**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | mapping   |             |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the information on all RPs and the multicast groups they serve.

**Examples**

```
Ruijie# show ipv6 pim sparse-mode rp mapping
PIM Group-to-RP Mappings
This system is the Bootstrap Router (v2)
Group(s): ff00::/8
  RP: 3333::1
      Info source: 3333::1, via bootstrap, priority 192
      Uptime: 00:12:40, expires: 00:01:50
```

## 7.44 show ipv6 pim sparse-mode rp-hash

Use this command to display the RP information corresponding to the group address.

**show ipv6 pim sparse-mode rp-hash** *ipv6-group-address*

| Parameter Description | Parameter                 | Description        |
|-----------------------|---------------------------|--------------------|
|                       | <i>ipv6_group-address</i> | IPv6 group address |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the RP information corresponding to the group address..

**Examples**

```
Ruijie# show ipv6 pim sparse-mode rp-hash ff66::6666
RP: 3333::8888
Info source: 3333::8888, via bootstrap
PIMv2 Hash Value 126
RP 3333::8888, via bootstrap, priority 192, hash value 1468234650
```

## 7.45 show ipv6 pim sparse-mode track

Use this command to display the number of sent and received PIM packets during the period from the beginning of the statistics till now.

**show ipv6 pim sparse-mode track**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Mode**

**Usage Guide** This command is used to display the number of sent and received PIM packets during the period from the beginning of the statistics till now.. When the system starts up, it sets the start time of the statistics. The start time of the statistics is reconfigured and the PIMv6 packet counter is cleared on calling the clear ipv6 pim sparse-mode track every time.

**Configuration Examples** The following example displays the number of sent and received PIM packets during the period from the beginning of the statistics till now.

```
Ruijie# show ipv6 pim sparse-mode track
PIMv6 packet counters track
Elapsed time since counters cleared: 00:04:03
                received      sent
Valid PIMSMv6 packets:      0          8
Hello:                       0          8
Join-Prune:                  0          0
Register:                    0          0
Register-Stop:               0          0
Assert:                      0          0
BSM:                         0          0
C-RP-ADV:                    0          0
PIMDMv6-Graft:               0
PIMDMv6-Graft-Ack:           0
PIMDMv6-State-Refresh:       0
Unknown PIMv6 Type:          0
Errors:
Malformed packets:                0
Bad checksums:                    0
Send errors:                      0
Packets received with unknown PIMv6 version: 0
```

## 8 IGMP Snooping Commands

### 8.1 clear ip igmp snooping gda-table

Use this command to clear the Group Destination Address (GDA) table.

**clear ip igmp snooping gda-table**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** The IGMP Snooping GDA table contains VLAN IDs (VIDs), group addresses, routing interface (static or dynamic) ID, and member interface ID. Among them, the VID and group address identify a forwarding entry; the static routing interfaces will not age and cannot be deleted by using the **clear ip igmp snooping gda-table** command.

**Configuration** The following example clears the Group Destination Address (GDA) table.

**Examples** Ruijie# clear ip igmp snooping gda-table

**Platform Description** N/A

### 8.2 clear ip igmp snooping statistics

Use this command to clear IGMP Snooping statistics.

**clear ip igmp snooping statistics**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to clear the IGMP Snooping statistics, which can be displayed by using the **show**

**ip igmp snooping statistics** command.

**Configuration** The following example clears the IGMP Snooping statistics.

**Examples** Ruijie# clear ip igmp snooping statistics

**Platform** N/A

**Description**

## 8.3 deny

Use this command to deny the forwarding of the multicast streams in the range specified by the profile.

**deny**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The forwarding of the multicast streams in the range specified by the profile is denied.

**Command Mode** Profile configuration mode

**Usage Guide** First, configure the multicast range using the range command in the profile configuration mode. In addition, the profile must be applied to the interface in order to make the profile configuration take effect.

**Configuration** The following is an example of deny the forwarding of the multicast stream 224.2.2.2 to 224.2.2.244.

**Examples** Ruijie(config)# ip igmp profile 1  
Ruijie(config-profile)# range 224.2.2.2 224.2.2.244  
Ruijie(config-profile)# deny

**Platform** N/A

**Description**

## 8.4 ip igmp profile

Use this command to create a profile and enter the IGMP profile configuration mode.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp profile** *profile-number*

**no ip igmp profile** *profile-number*

**default ip igmp profile** *profile-number*

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                       |                                             |
|-----------------------|---------------------------------------------|
| <i>profile-number</i> | Profile number, in the range from 1 to 1024 |
|-----------------------|---------------------------------------------|

**Defaults** No profile is created by default.

**Command Mode** Global configuration mode

**Usage Guide** The profile is a filter to permit/deny specified groups in the following steps:

- Use the **ip igmp profile** command to create a profile and enter profile configuration mode.
- Use the **range** command to define a profile range.
- Use the **permit** command to permit this profile in the filtering, or use the **deny** command to deny this profile in the filtering.
- If the **deny** command is used without any profile specified, all profiles in the profile are permitted.
- If the **permit** command is used without any profile specified, all profiles in the profile are denied.

**Configuration Examples** The following example creates and permits profile 1 with addresses from 224.2.2.2 to 224.2.2.244.

```
Ruijie(config)# ip igmp profile 1
Ruijie(config-profile)# range 224.2.2.2 224.2.2.244
Ruijie(config-profile)# permit
```

**Platform** N/A

**Description**

## 8.5 ip igmp snooping

Use this command to enable IGMP snooping and enter the IVGL mode.

**ip igmp snooping ivgl**

Use this command to enable IGMP snooping and enter the SVGL mode.

**ip igmp snooping svgl**

Use this command to enable IGMP snooping and enter the IVGL-SVGL mode.

**ip igmp snooping ivgl-svgl**

Use the **no** or **default** command to restore the default setting.

**no ip igmp snooping**

**default ip igmp snooping**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** IGMP Snooping is disabled by default.

**Command Mode** Global configuration mode

- Usage Guide**
- **IVGL (Independent VLAN Group Learning):** In this mode, the multicast flows in different VLANs are independent. A host can only request multicast flows to the router interface in the same VLAN. Upon receiving the multicast flow in any VLAN, the switch forwards the flow to the member port in the same VLAN.
  - **SVGL (Shared VLAN Group Learning):** In this mode, the hosts in different VLANs share the same multicast flow. A host can request multicast flows across VLANs. By designating a Shared VLAN, you can only forward the multicast flows received in this Shared VLAN to other member ports in different VLANs. In the SVGL mode, IGMP Profile must be used to divide the multicast address range, within which the multicast flow can be forwarded across VLANs. By default, all group range is not within the SVGL range and all multicast flows are dropped. As shown in Figure-3:
  - **IVGL-SVGL mode:** also known as promiscuous mode. In this mode, the IVGL mode and the SVGL mode can co-exist. Use IGMP Profile to divide a set of multicast address range to the SVGL, within which the member port of the multicast forwarding entry can be forwarded across VLANs and without which the member ports are forwarded in the same VLAN.
  - For wireless products, only IVGL mode is supported. Use the **ip igmp snooping** command to enable IGMP Snooping in global configuration mode, and use the **igmp snooping** command in AP configuration mode.

 SVGL mode and IVGL-SVGL mode conflict with the IP multicast function.

 PIM Snooping must depend on either IVGL or IVGL-SVGL mode of IGMP Snooping. Use **no ip igmp snooping** command to disable IGMP Snooping after PIM Snooping is disabled.

**Configuration** The following example enables IGMP Snooping and enters the IVGL mode.

**Examples** Ruijie(config)# ip igmp snooping ivgl

The following example enables IGMP Snooping and enters the SVGL mode.

```
Ruijie(config)# ip igmp snooping svgl
Ruijie(config)# ip igmp snooping svgl profile 1
```

The following example enables IGMP Snooping and enters the IVGL-SVGL mode.

```
Ruijie(config)# ip igmp snooping ivgl-svgl
Ruijie(config)# ip igmp snooping svgl profile 1
```

The following example enables IGMP Snooping on APs.

```
Ruijie(config)# ip igmp snooping
Ruijie(ap-config)# igmp snooping
```

**Platform** N/A  
**Description**

## 8.6 ip igmp snooping dyn-mr-aging-time

Use this command to set the aging time of a dynamic routing interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping dyn-mr-aging-time** *seconds*

**no ip igmp snooping dyn-mr-aging-time**

**default ip igmp snooping dyn-mr-aging-time**

| Parameter Description | Parameter      | Description                                       |
|-----------------------|----------------|---------------------------------------------------|
|                       | <i>seconds</i> | Aging time from 1 to 3,600 in the unit of seconds |

**Defaults** The default is 300 seconds.

**Command Mode** Global configuration mode

**Usage Guide** If a dynamic routing interface does not receive IGMP query packets or PIM hello packets before aged, this interface will be deleted.  
When the dynamic routing interface learning function is enabled, this command sets the aging time of the routing interface. If the aging time is set too short, the routes may be added and deleted frequently.

**Configuration Examples** The following example sets the aging time of the routing interface that the switch learns dynamically to 100 seconds.

```
Ruijie(config)# ip igmp snooping dyn-mr-aging-time 100
```

**Platform Description** N/A

## 8.7 ip igmp snooping fast-leave enable

Use this command to enable the fast leave function.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping fast-leave enable**

**no ip igmp snooping fast-leave enable**

**default ip igmp snooping fast-leave enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Command Mode</b>  | Global configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Usage Guide</b>   | <p>After you execute this command to enable the fast-leave function, the system will remove the corresponding multicast group on the corresponding interface upon the receipt of the IGMP leave message.</p> <p>Subsequently, when the system receives a specific group query packet, the system does not forward it to the corresponding interface. Leave packets refer to the IGMPv2 leave packets. The fast leave function applies to scenarios in which one interface is connected to only one host. This function saves bandwidth and resources.</p> |
| <b>Configuration</b> | The following example enables the fast leave function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Examples</b>      | <pre>Ruijie(config)# ip igmp snooping fast-leave</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Platform</b>      | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## 8.8 ip igmp snooping filter

Use this command to specify the profile for ports.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping filter** *profile-number*

**no ip igmp snooping filter** *profile-number*

**default ip igmp snooping filter**

Use this command to specify the profile for VLANs.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping vlan** *vlan-id* **filter** *profile-number*

**no ip igmp snooping vlan** *vlan-id* **filter**

**default ip igmp snooping vlan** *vlan-id* **filter**

| Parameter Description | Parameter             | Description                   |
|-----------------------|-----------------------|-------------------------------|
|                       | <i>profile-number</i> | Profile number from 1 to 1024 |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode/Interface configuration mode

**Usage Guide** A specific profile must be created before association.

**Configuration** The following example specifies profile 1 for interface fastEthernet 0/1.

**Examples**

```
Ruijie(config)# interface fastEthernet 0/1
```

```
Ruijie(config-if)# ip igmp snooping filter 1
```

**Platform** N/A

**Description**

## 8.9 ip igmp snooping host-aging-time

Use this command to configure the aging time of IGMP dynamic ports.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping host-aging-time** *seconds*

**no ip igmp snooping host-aging-time**

**default ip igmp snooping host-aging-time**

| Parameter          | Parameter      | Description                                                        |
|--------------------|----------------|--------------------------------------------------------------------|
| <b>Description</b> | <i>seconds</i> | Aging time. The unit is second. The value ranges from 1 to 65,535. |

**Defaults** The default is 260 seconds.

**Command Mode** Global configuration mode

**Usage Guide** The aging time of a dynamic port is set by the system when the port receives an IGMP packet from the host for joining a certain IP multicast group. When such an IGMP packet is received, the system resets the aging timer for the port. The duration of this timer is determined by **host-aging-time**. If the timer expires, the system determines that there is no host in this port for receiving multicast packets. The multicast device removes the port from the IGMP Snooping group. After the **ip igmp snooping host-aging-time** command is executed, the aging time will be determined by **host-aging-time**. This command takes effect only after the system receives the next IGMP packet. This command does not change the current aging time.

**Configuration Examples** The following example sets the aging time to 30 seconds.

```
Ruijie(config)# ip igmp snooping host-aging-time 30
```

| Related Commands | Command | Description |

**Description**

## 8.10 ip igmp snooping l2-entry-limit

Use this command to set the maximum number of multicast groups.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping l2-entry-limit** *number*  
**no ip igmp snooping l2-entry-limit**  
**default ip igmp snooping l2-entry-limit**

| Parameter   | Parameter     | Description                                                    |
|-------------|---------------|----------------------------------------------------------------|
| Description | <i>number</i> | Number of multicast groups. The value ranges from 0 to 65,536. |

**Defaults** The default is 65,536.

**Command Mode** Global configuration mode

**Usage Guide** The maximum number of multicast groups includes the multicast groups in all ports of all VLANs (including dynamic and static multicast groups). When the number of multicast groups reaches the limit, learning new group records and configuring new static multicast group ports are not allowed.

**Configuration** The following example sets the maximum number of multicast groups to 2000.

**Examples** Ruijie(config)# ip igmp snooping l2-entry-limit 2000

| Related Commands | Command                      | Description                                      |
|------------------|------------------------------|--------------------------------------------------|
|                  | <b>show ip igmp snooping</b> | Displays the maximum number of multicast groups. |

**Platform Description** N/A

## 8.11 ip igmp snooping limit-ipmc

Use this command to add a multicast source IP address check entry.

Use the **no** or **default** form of this command is used to delete a source IP checklist entry.

**ip igmp snooping limit-ipmc** *vlan vid address gaddress server saddress*

**no ip igmp snooping limit-ipmc** *vlan vid address gaddress*

**default ip igmp snooping limit-ipmc** *vlan vid address gaddress*

| Parameter   | Parameter             | Description                 |
|-------------|-----------------------|-----------------------------|
| Description | <i>vid</i>            | VLAN ID                     |
|             | <i>group-address</i>  | Multicast group address     |
|             | <i>source-address</i> | Multicast source IP address |

**Defaults** Only source IP address check is enabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to filter the multicast packets. With it enabled, all multicast packets from illegal IP addresses will be discarded.

 Source IP address check and multicast routing function cannot be enabled meanwhile.

Configuration steps:

1. Enable source IP address check and specify the source IP address.
2. (Optional) Specify the multicast group address and source IP address for a specific VLAN.

**Configuration Examples** The following example enables source address check to receive multicast packets only from 192.168.1.10 and allows packets into VLAN 203 and VLAN 104 from (192.168.1.10 , 229.1.1.1).

```
Ruijie# configure terminal
Ruijie(config)# ip igmp snooping source-check default-server 192.168.1.10
Ruijie(config)# ip igmp snooping limit-ipmc vlan 203 address 229.1.1.1 server
192.168.1.10
Ruijie(config)# ip igmp snooping limit-ipmc vlan 204 address 229.1.1.1 server
192.168.1.10
Ruijie(config)# end
```

**Platform** N/A

**Description**

## 8.12 ip igmp snooping max-groups

Use this command to configure the maximum number of groups that can be added dynamically to this interface.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping max-groups** *number*

**no ip igmp snooping max-groups**

**default ip igmp snooping max-groups**

| Parameter Description | Parameter     | Description                              |
|-----------------------|---------------|------------------------------------------|
|                       | <i>number</i> | The maximum group number from 0 to 1,024 |

**Defaults** No maximum group number is configured by default.

**Command Mode** Interface configuration mode

**Usage Guide** If a maximum number of multicast groups are configured, the device will no longer receive and process IGMP Report messages when the number of multicast groups on this interface is beyond the range.

**Configuration Examples** The following example configures the maximum number of multicast groups to 100 on the megabit interface 0/1:

```
Ruijie(config)# interface Ethernet 0/1
Ruijie(config-if)# ip igmp snooping max-group 100
```

**Platform** N/A

**Description**

## 8.13 ip igmp snooping mrouter learn pim-dvmrp

Use this command to configure a device to listen to the IGMP Query/Dvmrp or PIM Help packets dynamically in order to automatically identify a routing interface

Use the **no** form of this command to disable the dynamic learning.

Use the **default** form of this command to restore the default setting.

**ip igmp snooping [ vlan *vid* ] mrouter learn pim-dvmrp**

**no ip igmp snooping [ vlan *vid* ] mrouter learn pim-dvmrp**

**default ip igmp snooping [ vlan *vid* ] mrouter learn pim-dvmrp**

**Parameter Description**

| Parameter              | Description                                                           |
|------------------------|-----------------------------------------------------------------------|
| <b>vlan <i>vid</i></b> | VLAN ID. By default, the specified version is supported on all VLANs. |

**Defaults** This function is enabled by default.

**Command**

**Mode** Global configuration mode

**Usage Guide**

Routing interface is a port through which a multicast device (with IGMP Snooping enabled) is directly connected to a multicast neighbouring device (with multicast routing protocols enabled).

By default, the dynamic routing interface learning function is enabled. You can use the no form of this command to disable this function and clear all routing interfaces learnt dynamically. With dynamic routing interface learning function disabled globally, the function of all vlans will be disabled. Beside, with this function enabled globally, if the function of specified vlan is disabled, the dynamic routing interface learning function of the corresponding vlan is disabled. When the source port check function is enabled, only the multicast flow enters from the routing interface is legal and it is forwarded to the registered interface by the multicast equipment, the multicast flow from the non routing interface is considered to be the illegal and is discarded. With the source port check function enabled, the dynamic routing interface learning function will improve the application flexibility of IGMP snooping.

**Configuration** The following example enables the dynamic routing interface learning function on VLAN 1.

**Examples**

```
Ruijie(config)# no ip igmp snooping mrouter learn pim-dvmrp
Ruijie(config)# ip igmp snooping vlan 1 mrouter learn pim-dvmrp
```

**Platform** N/A

**Description**

## 8.14 ip igmp snooping preview

Use this command to allow the user to preview the specific multicast streams when the user doesn't have access to such multicast streams.

Use **no** or **default** form of this command to disable multicast preview.

**ip igmp snooping preview** *profile-number*

**no ip igmp snooping preview**

**default ip igmp snooping preview**

| Parameter Description | Parameter             | Description             |
|-----------------------|-----------------------|-------------------------|
|                       | <i>profile-number</i> | Profile number (1-1024) |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Apply the IGMP Profile to a multicast preview function. When the user doesn't have access to the multicast streams (namely the user might be filtered by IGMP Snooping filter), it can allow the user to preview partial contents. This function shall be used in conjunction with IGMP Snooping filter or multicast control in order to realize effective multicast preview.

**Configuration Examples** The following example associates the profile 2 to the Ethernet 0/1 and associates multicast preview with profile 1.

```
Ruijie(config)# ip igmp snooping preview 1
Ruijie(config-if)# int Ethernet 0/1
Ruijie(config-if)# ip igmp snooping filter 2
```

**Platform Description** N/A

## 8.15 ip igmp snooping preview interval

Use this command to configure the interval that allows the user to preview the specific multicast streams when the user doesn't have access to such multicast streams.

Use **no** or **default** form of this command to restore the default setting.

**ip igmp snooping preview interval** *seconds*

**no ip igmp snooping preview interval**

**default ip igmp snooping preview interval**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                |                                                       |
|----------------|-------------------------------------------------------|
| <i>seconds</i> | Preview interval from 1 to 300 in the unit of seconds |
|----------------|-------------------------------------------------------|

**Defaults** The default is 60 seconds.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the multicast preview interval as 100 seconds on the 100M port of 0/1:

```
Ruijie(config)# ip igmp snooping preview 1
Ruijie(config)# ip igmp snooping preview interval 100
```

**Platform** N/A

**Description**

## 8.16 ip igmp snooping querier

Use this command to enable the IGMP querier.

Use **no** or **default** form of this command to restore the default setting.

**ip igmp snooping [ vlan *vid* ] querier**

**no ip igmp snooping [ vlan *vid* ] querier**

**default ip igmp snooping [ vlan *vid* ] querier**

| Parameter Description | Parameter              | Description                                                           |
|-----------------------|------------------------|-----------------------------------------------------------------------|
|                       | <b>vlan <i>vid</i></b> | VLAN ID. By default, the specified version is supported on all VLANs. |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** After globally enabling the IGMP querier, you must enable the IGMP querier function in VLAN to activate this function.

If the IGMP querier function is disabled globally, the IGMP querier will be disabled in all VLANs.

**Configuration Examples** The following example enables the IGMP querier function in VLAN 2.

```
Ruijie(config)# ip igmp snooping querier
Ruijie(config)# ip igmp snooping vlan 2 querier
```

**Platform** N/A

**Description**

## 8.17 ip igmp snooping querier address

Use this command to specify a source IP address for IGMP querier.

Use **no** or **default** form of this command to remove the source IP address configured.

**ip igmp snooping [ vlan *vid* ] querier address *a.b.c.d***

**no ip igmp snooping [ vlan *vid* ] querier address**

**default ip igmp snooping [ vlan *vid* ] querier address**

| Parameter Description | Parameter              | Description                                                           |
|-----------------------|------------------------|-----------------------------------------------------------------------|
|                       | <b>vlan <i>vid</i></b> | VLAN ID. By default, the specified version is supported on all VLANs. |
|                       | <b><i>a.b.c.d</i></b>  | Source IP address of the IGMP querier                                 |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** After enabling IGMP querier, you must configure a source IP address for the IGMP querier to activate this function..

If the IGMP querier source IP has been specified in VLAN, the source IP configured in the relevant VLAN will be used first.

**Configuration Examples** The following example specifies the source IP of the IGMP querier as 1.1.1.1 on the device.

```
Ruijie(config)# ip igmp snooping querier address 1.1.1.1
```

The following example specifies the source IP of the IGMP querier as 1.1.1.1 in VLAN 3.

```
Ruijie(config)# ip igmp snooping vlan 3 querier address 1.1.1.1
```

**Platform Description**

## 8.18 ip igmp snooping querier max-response-time

Use this command to configure the maximum response time of the IGMP querier.

Use **no** or **default** form of this command to restore to the default setting.

**ip igmp snooping [ vlan *vid* ] querier max-response-time *seconds***

**no ip igmp snooping [ vlan *vid* ] querier max-response-time**

**default ip igmp snooping [ vlan *vid* ] querier max-response-time**

| Parameter Description | Parameter              | Description                                                           |
|-----------------------|------------------------|-----------------------------------------------------------------------|
|                       | <b><i>seconds</i></b>  | Maximum response time from 1 to 25 in the unit of seconds             |
|                       | <b>vlan <i>vid</i></b> | VLAN ID. By default, the specified version is supported on all VLANs. |

|                               |                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | The default is 10 seconds.                                                                                                                                                                                                                                                                                                                           |
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                                                                                                                                                                                                            |
| <b>Usage Guide</b>            | By default, the maximum response time is 10 seconds. If the maximum response time has been specified in the corresponding VLAN, the value specified in VLAN will be used first.                                                                                                                                                                      |
| <b>Configuration Examples</b> | The following example specifies the maximum response time of the IGMP querier on the device.<br><pre>Ruijie(config)# ip igmp snooping querier max-response-time 15</pre> The following example specifies the maximum response time of the IGMP querier in VLAN 3.<br><pre>Ruijie(config)# ip igmp snooping vlan 3 querier max-response-time 15</pre> |
| <b>Platform Description</b>   | N/A                                                                                                                                                                                                                                                                                                                                                  |

## 8.19 ip igmp snooping querier query-interval

Use this command to specify the interval for IGMP querier to send query packets.

Use **no** or **default** form of this command to restore the default setting.

**ip igmp snooping [ vlan *vid* ] querier query-interval *seconds***

**no ip igmp snooping [ vlan *vid* ] querier query-interval**

**default ip igmp snooping [ vlan *vid* ] querier query-interval**

| Parameter Description | Parameter              | Description                                                           |
|-----------------------|------------------------|-----------------------------------------------------------------------|
|                       | <i>seconds</i>         | Query interval from 1 to 18,000 in the unit of seconds                |
|                       | <b>vlan <i>vid</i></b> | VLAN ID. By default, the specified version is supported on all VLANs. |

|                               |                                                                                                                                                                                                                                                                                              |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | The default is 60 seconds.                                                                                                                                                                                                                                                                   |
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                                                                                                                                                    |
| <b>Usage Guide</b>            | If the query interval has been configured in the corresponding VLAN, the value specified in VLAN will be used first.                                                                                                                                                                         |
| <b>Configuration Examples</b> | The following example configures the query interval on the device.<br><pre>Ruijie(config)# ip igmp snooping querier query-interval 100</pre> The following example configures the query interval in VLAN 3.<br><pre>Ruijie(config)# ip igmp snooping vlan 3 querier query-interval 100</pre> |
| <b>Platform</b>               | N/A                                                                                                                                                                                                                                                                                          |

**Description**

## 8.20 ip igmp snooping querier timer expiry

Use this command to specify the expiration timer for non-querier.

Use **no** form of this command to restore the default setting.

**ip igmp snooping [ vlan *vid* ] querier timer expiry *seconds***

**ip igmp snooping [ vlan *vid* ] querier timer expiry *seconds***

**default ip igmp snooping [ vlan *vid* ] querier timer expiry**

| Parameter Description | Parameter       | Description                                                           |
|-----------------------|-----------------|-----------------------------------------------------------------------|
|                       | <i>seconds</i>  | The expiration timer from 60 to 300 in the unit of seconds            |
|                       | <i>vlan vid</i> | VLAN ID. By default, the specified version is supported on all VLANs. |

**Defaults** The default is 125 seconds.

**Command Mode** Global configuration mode

**Usage Guide** After globally enabling IGMP querier, if the device is elected as a non-querier, execute this command to change the expiration timer for non-querier.  
If expiration timer has been configured in the corresponding VLAN, the value specified in VLAN will be used first.

**Configuration** The following example configures the non-querier expiration timer on the device.

**Examples**

```
Ruijie(config)# ip igmp snooping querier timer expiry 60
```

The following example configures the non-querier expiration timer in VLAN 3.

```
Ruijie(config)# ip igmp snooping vlan 3 querier timer expiry 60
```

**Platform** N/A

**Description**

## 8.21 ip igmp snooping querier version

Use the following commands to specify IGMP Snooping querier version.

**ip igmp snooping [ vlan *vid* ] querier version 1**

**ip igmp snooping [ vlan *vid* ] querier version 2**

**ip igmp snooping [ vlan *vid* ] querier version 3**

Use **no** or **default** form of this command to restore to the default setting.

**no ip igmp snooping [ vlan *vid* ] querier version**

**default ip igmp snooping [ vlan *vid* ] querier version**

| <b>Parameter Description</b>  | Parameter                                                                                                       | Description                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
|                               | <code>vlan vid</code>                                                                                           | VLAN ID. By default, the specified version is supported on all VLANs. |
| <b>Defaults</b>               | The default version is IGMPv2.                                                                                  |                                                                       |
| <b>Command Mode</b>           | Global configuration mode                                                                                       |                                                                       |
| <b>Usage Guide</b>            | If an IGMP querier version has been configured in a VLAN, the version specified in the VLAN will be used first. |                                                                       |
| <b>Configuration Examples</b> | The following example configures IGMP querier version on the device.                                            |                                                                       |
|                               | <pre>Ruijie(config)# ip igmp snooping querier version 1</pre>                                                   |                                                                       |
| <b>Platform Description</b>   | N/A                                                                                                             |                                                                       |

## 8.22 ip igmp snooping query-max-response-time

Use this command to specify the time for the switch to wait for the member join message after receiving the **query** message.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping query-max-response-time** *seconds*

**no ip igmp snooping query-max-resposne-time**

**default ip igmp snooping query-max-response-time**

| <b>Parameter Description</b> | Parameter      | Description                                                                                               |
|------------------------------|----------------|-----------------------------------------------------------------------------------------------------------|
|                              | <i>seconds</i> | The aging time of the routing interface that the switch learns dynamically, in the range from 1 to 65.535 |

**Defaults** The default is 10 seconds.

**Command Mode** Global configuration mode

**Usage Guide** You can specify the time for the switch to wait for the member join message after receiving the query message. If the switch does not receive the member join message in the specified time, it considers that the member has left and then deletes the member.

This command lets you adjust the waiting time after receiving the query message. This command takes effect only after the switch receives the next member join message. This command does not change the current wait time.

**Configuration** The following examples sets the aging time of the routing interface that the switch learns dynamically to 100 seconds.

**Examples**

```
Ruijie(config)# ip igmp snooping query-max-response-time 100
```

**Platform** N/A

**Description**

## 8.23 ip igmp snooping source-check default-server

Use this command to enable the source IP address check to permit one or several IPMC flows from the server of the specified IP address.

Use the **no** or **default** form of this command is used to restore the default setting.

**ip igmp snooping source-check default-server** *source-address*

**no ip igmp snooping source-check**

**default ip igmp snooping source-check**

| Parameter Description | Parameter             | Description                         |
|-----------------------|-----------------------|-------------------------------------|
|                       | <i>source-address</i> | Default multicast source IP address |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** The source IP address check function takes effect globally. Once it is enabled, only the IPMC streams from the specified IP address are permitted.

 Source IP address check and IP multicast function cannot work meanwhile.

The device allows users to configure the source IP address of all IPMC streams, called default multicast server. The default server must be set as long as the source IP address check function is enabled.

**Configuration** The following example enables the multicast source IP address check function.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip igmp snooping source-check default-server 192.168.1.10
Ruijie(config)# ip igmp snooping limit-ipmc vlan 203 address 229.1.1.1 server
192.168.1.10
Ruijie(config)# ip igmp snooping limit-ipmc vlan 204 address 229.1.1.1 server
192.168.1.10
Ruijie(config)# end
```

**Platform** N/A

**Description**

## 8.24 ip igmp snooping source-check port

Use this command to enable the source port check function of IGMP Snooping.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping source-check port**

**no ip igmp snooping source-check port**

**default ip igmp snooping source-check port**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** The source port check function is used to permit one or several IPMC flows from the mroute port. When it is enabled, only the IPMC streams from the specified port are permitted. When it is disabled, all the IPMC streams are permitted and forwarded.

**Configuration Examples** The following example enables the source port check function of IGMP Snooping.

```
Ruijie(config)# ip igmp snooping source-check port
```

**Platform Description** N/A

## 8.25 ip igmp snooping suppression enable

Use this command to enable IGMP snooping suppression.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping suppression enable**

**no ip igmp snooping suppression enable**

**default ip igmp snooping suppression enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** When this function is enabled, IGMP Snooping only forwards the first report from a specific VLAN or group, and suppresses the following reports to constrain traffic in the networks.  
This function is only supported on IGMPv1 and IGMPv2 reports.

**Configuration** The following example enables IGMP snooping suppression on the device.

**Examples**

```
Ruijie(config)# ip igmp snooping suppression enable
```

**Platform** N/A

**Description**

## 8.26 ip igmp snooping svgl profile

Use this command to specify the multicast group address range applied in the SVGL/IVGL-SVGL mode.  
Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping svgl profile** *profile-number*

**no ip igmp snooping svgl profile**

**default ip igmp snooping svgl profile**

| Parameter Description | Parameter             | Description                             |
|-----------------------|-----------------------|-----------------------------------------|
|                       | <i>profile-number</i> | Profile number, in the range of 1-1,024 |

**Defaults** No profile is associated.

**Command Mode** Global configuration mode

**Usage Guide** When the IGMP Snooping works in the SVGL and IVGL-SVGL mode, a profile shall be associated to specify the multicast group address range applied in the SVGL or IVGL-SVGL mode. That is to say, the member ports of the multicast forwarding entry can be forwarded across the VLANs while the member ports of the multicast forwarding entry in the other multicast address range must belong to the same VLAN.

**Configuration** The following example specifies the profile 2 applied in SVGL mode.

**Examples**

```
Ruijie(config)# ip igmp snooping svgl profile 2
```

**Platform** N/A

**Description**

## 8.27 ip igmp snooping svgl subvlan

Use this command to specify the subvlan of multicast VLAN.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping svgl subvlan** [*vid-range*]

**no ip igmp snooping svgl subvlan** [*vid-range*]

**default ip igmp snooping svgl subvlan** [*vid-range*]

| Parameter Description | Parameter        | Description                 |
|-----------------------|------------------|-----------------------------|
|                       | <i>vid-range</i> | VLAN ID or range of VLAN ID |

**Defaults** By default, all VLANs except shared VLANs serve as its sub VLANs.

**Command Mode** Global configuration mode

**Usage Guide** This command only takes effect in SVGL and IVGL-SVGL mode.

**Configuration Examples** The following example specifies VLAN 3 as the shared VLAN and VLAN 2, VLAN 5 to 7 as the sub VLANs.

```
Ruijie(config)# ip igmp snooping svgl vlan 3
Ruijie(config)# ip igmp snooping svgl subvlan 2,5-7
```

**Platform Description** N/A

## 8.28 ip igmp snooping svgl vlan

Use this command to specify the shared VLAN in SVGL mode.

Use the **no** form of this command to restore the default setting.

**ip igmp snooping svgl vlan** *vid*

**no ip igmp snooping svgl vlan**

**default ip igmp snooping svgl vlan**

| Parameter Description | Parameter  | Description |
|-----------------------|------------|-------------|
|                       | <i>vid</i> | VLAN ID     |

**Defaults** By default , the shared VLAN is VLAN 1.

**Command Mode** Global configuration mode

**Usage Guide** This command only works in the SVGL and IVGL-SVGL mode.

**Configuration** The following example specifies VLAN 3 as the shared VLAN and VLAN 2, VLAN 5 to 7 as the sub

**Examples**

VLANs.

```
Ruijie(config)# ip igmp snooping svgl vlan 3
Ruijie(config)# ip igmp snooping svgl subvlan 2,5-7
```

**Platform**

N/A

**Description**

## 8.29 ip igmp snooping tunnel

Use this command to enable 802.1Q tunneling (QinQ) support for IGMP Snooping.

Use the **no** or **default** form of this command to restore the default setting.

**ip igmp snooping tunnel**

**no ip igmp snooping tunnel**

**default ip igmp snooping tunnel**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

This function is disabled.

**Command Mode**

Global configuration mode

**Usage Guide**

After IGMP Snooping is enabled and dot1q-tunnel port is configured on the device, IGMP packets received from dot1q-tunnel port will be handled in two ways:

- First: QinQ transmits IGMP packets transparently. Create multicast entries in the VLAN to which the IGMP packets belong, and forward IGMP packets in the VLAN.
- For example: It is assumed that IGMP Snooping has been enabled on the device; Port A is a dot1q-tunnel port; the default VLAN of Port A is VLAN 1, and packets from VLAN 1 and VLAN 10 are allowed by Port A. When multicast requests of VLAN 10 are sent to port A, IGMP Snooping will create the multicast entry of VLAN 10 and forward the multicast requests to the router port of VLAN 10.
- Second: Create multicast entries in the default VLAN to which the dot1q-tunnel ports belong, and forward multicast packets in the default VLAN of dot1q-tunnel port after inserting the VLAN Tag of the default VLAN of dot1q-tunnel port.
- For example: It is assumed that IGMP Snooping has been enabled on the device; Port A is a dot1q-tunnel port; the default VLAN of port A is VLAN 1, and packets from VLAN 1 and VLAN 10 are allowed Port A. When multicast requests of VLAN 10 are sent to Port A, IGMP Snooping will create the multicast entry of VLAN 1 and insert the VLAN Tag of VLAN 1 into multicast requests before forwarding the multicast requests to the router port of VLAN 1.

By default, the second way is used.

**Configuration** The following example enables QinQ support for IGMP Snooping.

**Examples** `Ruijie(config)# ip igmp snooping tunnel`

**Platform** N/A

**Description**

## 8.30 ip igmp snooping vlan

Use this command to enable the IGMP Snooping in the specified VLAN and enter IVGL mode.

Use the **no** form of this command is used to disable the IGMP Snooping.

Use the **default** form of this command to restore the default setting.

**ip igmp snooping vlan** *vid*

**no ip igmp snooping vlan** *vid*

**default ip igmp snooping vlan** *vid*

| Parameter Description | Parameter  | Description                          |
|-----------------------|------------|--------------------------------------|
|                       | <i>vid</i> | VLAN ID in the range from 1 to 4,094 |

**Defaults** IGMP Snooping is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to enable or disable the IGMP snooping on the specified vlan.

 The PIM Snooping in the specified VLAN works only when IGMP Snooping is configured. To disable PIM Snooping, you must disable IGMP Snooping in the VLAN first, or disabling will fail and be prompted.

**Configuration Examples** The following example enters IVGL mode and disables the IGMP Snooping in the VLAN 2.

```
Ruijie(config)# ip igmp snooping ivgl
Ruijie(config)# no ip igmp snooping vlan 2
```

**Platform** N/A

**Description**

## 8.31 ip igmp snooping vlan mrouter interface

Use this command to configure a static routing interface.

Use the **no** form of this command to delete a static routing interface.

Use the **default** form of this command to restore the default setting.

**ip igmp snooping vlan** *vid* **mrouter interface** *interface-type interface-number*

**no ip igmp snooping vlan** *vid* **mrouter interface** *interface-type interface-number*

**default ip igmp snooping vlan** *vid* **mrouter interface** *interface-type interface-number*

| Parameter Description | Parameter                                        | Description                          |
|-----------------------|--------------------------------------------------|--------------------------------------|
|                       | <i>vid</i>                                       | VLAN ID in the range from 1 to 4,094 |
|                       | <i>interface-type</i><br><i>interface-number</i> | Interface ID                         |

**Defaults** No static routing interface is configured by default.

**Command Mode** Global configuration mode

**Usage Guide** A dynamic routing interface is learned dynamically through IGMP Snooping. A static routing interface is configured by using this command and cannot age.

When an interface is configured as a static routing interface, all multicast streams received on this interface will be forwarded.

When the source port check function is enabled, only the multicast flows from the routing interface are forwarded, and other flows will be discarded.

**Configuration** The following example configures a static routing interface.

**Examples**

```
Ruijie(config)# ip igmp snooping vlan 1 mrouter interface fastEthernet 0/1
```

**Platform Description** N/A

## 8.32 ip igmp snooping vlan static interface

Use this command to configure a static member interface of a multicast group.

Use the **no** form of this command to delete a static member interface from a multicast group.

Use the **default** form of this command to restore the default setting.

**ip igmp snooping vlan** *vid* **static** *group-address* **interface** *interface-type interface-number*

**no ip igmp snooping vlan** *vid* **static** *group-address* **interface** *interface-type interface-number*

**default ip igmp snooping vlan** *vid* **static** *group-address* **interface** *interface-type interface-number*

| Parameter Description | Parameter           | Description                          |
|-----------------------|---------------------|--------------------------------------|
|                       | <i>vid</i>          | VLAN ID in the range from 1 to 4,094 |
|                       | <i>ip-addr</i>      | Multicast IP address                 |
|                       | <i>interface-id</i> | Interface ID                         |

**Defaults** No static member interface of any multicast group is configured by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** The IGMP Snooping GDA table contains VLAN IDs (VIDs), group addresses, routing interface (static or dynamic) ID, and member interface ID. Among them, the VID and group address identify a forwarding entry; the static routing interfaces will not age and cannot be deleted by using the **clear ip igmp snooping gda-table** command.

**Configuration** The following example configures a static member interface for the multicast group 224.1.1.1.

**Examples**

```
Ruijie(config)# ip igmp snooping vlan 1 static 224.1.1.1 interface
GigabitEthernet 0/1
```

**Platform** N/A

**Description**

## 8.33 permit

Use this command to permit the multicast forwarding for specified ranges of a specified profile.

### permit

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The forwarding of the multicast streams in the range specified by the profile is denied.

**Command**

**Mode**

Profile configuration mode

**Usage Guide** A profile is used to filter a group of multicast packets, so as to assist other features.

Configuration steps:

1. Use the **ip igmp profile** command to create a profile and enter profile configuration mode.
2. Use the **range** command to define a range for the profile.
3. Use the **permit** command to permit the multicast forwarding for the profile.

**Configuration Examples** The following example permits the forwarding of the multicast streams from 224.2.2.2 to 224.2.2.244 of profile 1.

```
Ruijie(config)# ip igmp profile 1
Ruijie(config-profile)# range 224.2.2.2 224.2.2.244
Ruijie(config-profile)# permit
```

**Platform** N/A

**Description**

## 8.34 range

Use this command to define a range for a specific profile.

Use the **no** form of the command to remove the range from the profile.

**range** *low-ip-address* [*high-ip-address*]

**no range** *low-ip-address* [*high-ip-address*]

| Parameter Description | Parameter              | Description              |
|-----------------------|------------------------|--------------------------|
|                       | <i>low-ip-address</i>  | Start address of a range |
|                       | <i>high-ip-address</i> | End address of a range   |

**Defaults** No range is defined for a profile by default.

**Command Mode** Profile configuration mode

**Usage Guide** A profile is used to filter a group of multicast packets, so as to assist other features.

Configuration steps:

1. Use the **ip igmp profile** command to create a profile and enter profile configuration mode.
2. Use the **range** command to define a range for the profile.
3. Use the **permit** command to permit the multicast forwarding for the profile.

**Configuration Examples** The following is an example of allowingpermits the forwarding of the multicast streams from 224.2.2.2 to 224.2.2.244: of profile 1.

```
Ruijie(config)# ip igmp profile 1
Ruijie(config-profile)# range 224.2.2.2 224.2.2.244224.2.2.2
Ruijie(config-profile)# permit
```

**Platform** N/A

**Description**

## 8.35 show ip igmp profile

Use this command to display the profile information.

**show ip igmp profile** *profile-number*

| Parameter Description | Parameter             | Description                                                   |
|-----------------------|-----------------------|---------------------------------------------------------------|
|                       | <i>profile-number</i> | Displays configuration information of the designated profile. |

**Defaults** N/A

|                      |                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------|
| <b>Command Mode</b>  | Privileged EXEC mode                                                                                 |
| <b>Usage Guide</b>   | Use this command to display the profile information.                                                 |
| <b>Configuration</b> | The following example displays the profile information.                                              |
| <b>Examples</b>      | <pre>Ruijie(config-if)# show ip igmp profile Profile 1 Permit range 224.0.1.0, 239.255.255.255</pre> |

## 8.36 show ip igmp snooping

Use this command to display related information of IGMP Snooping.

**show ip igmp snooping** [**gda-table** | **interfaces** *interface-type interface-number* | **mdevice** | **statistics** [**vlan** *vlan-id*] | **querier** [ **detail** | **vlan** *vid* ] | **user-info** ]

| Parameter Description | Parameter                                        | Description                                                                |
|-----------------------|--------------------------------------------------|----------------------------------------------------------------------------|
|                       | <b>vlan</b> <i>vid</i>                           | VLAN ID. By default, IGMP Snooping information of all VLANs are displayed. |
|                       | <i>interface-type</i><br><i>interface-number</i> | Interface type and number                                                  |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays global IGMP Snooping information.

|                 |                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Platform** N/A

**Description**

## 9 MLD Snooping Commands

### 9.1 clear ipv6 mld snooping gda-table

Use this command to clear the forwarding table information learned dynamically.

**clear ipv6 mld snooping gda-table**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear the forwarding table information learned dynamically.

**Configuration Examples** The following example clears the forwarding table information learned dynamically:

```
Ruijie# clear ipv6 mld snooping gda-table
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 9.2 clear ipv6 mld snooping statistics

Use this command to clear the MLD Snooping statistics, including the entry number, the entry volume, the number of various received packets, the group information and the interface information of the corresponding group.

**clear ipv6 mld snooping statistics**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use the **show ipv6 mld snooping statistics** command to verify the configuration.

**Configuration Examples** The following example clears the MLD Snooping statistics.

```
Ruijie# clear ipv6 mld snooping statistics
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 9.3 deny

Use this command to prevent the multicast flow profile within the specified range from being forwarded in the profile configuration mode.

**deny**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The default profile action is **deny**.

**Command Mode** Profile configuration mode

**Usage Guide** Profile is a kind of group “filter” that can be referred to by other functions.  
Configuration Steps:

1. Use the **ipv6mld profile** command to create a profile and enter the profile mode.
2. Use the **range** command to define a group.
3. Use the **permit** command to allow this group to pass the filtering; Use the **deny** command to filter the packets of this group. The default command is **deny**.

**Configuration Examples** The following example prevents the multicast flow profile within the range from FF15::1 to FF15::100 from being forwarded.

```
Ruijie(config)# ipv6 mld profile 1
Ruijie(config-profile)# range FF15::1 FF15::100
Ruijie(config-profile)# deny
```

| Related | Command | Description |
|---------|---------|-------------|
|---------|---------|-------------|

| Commands                |                                   |
|-------------------------|-----------------------------------|
| <b>ipv6 mld profile</b> | Creates one profile.              |
| <b>range</b>            | Sets the multicast address range. |
| <b>permit</b>           | Sets the profile action permit.   |

**Platform** N/A

**Description**

## 9.4 ipv6 mld profile

Use the following command to create a profile.

Use the **no** or **default** form of this command to delete a profile.

**ipv6 mld profile** *profile-number*

**no ipv6 mld profile** *profile-number*

**default ipv6 mld profile** *profile-number*

| Parameter Description | Parameter             | Description                                  |
|-----------------------|-----------------------|----------------------------------------------|
|                       | <i>profile-number</i> | Profile number, in the range from 1 to 1024. |

**Defaults** N/A

**Command** Global configuration mode

**Mode**

**Usage Guide** Profile is a kind of group “filter” that can be referred to by other functions.  
 Configuration Steps:

1. Use the **ipv6mld profile** command to create a profile and enter the profile mode.
2. Use the **range** command to define a group.
3. Use the **permit** command to allow this group to pass the filtering; Use the **deny** command to filter the packets of this group. The default command is **deny**.

**Configuration Examples** The following example creates profile 1 and allows the packets sent by devices with MAC address ranging from FF15::1 to FF15::100 to pass the filtering.

```
Ruijie(config)#ipv6 mld profile 1
Ruijie(config-profile)#range FF15::1 FF15::100
Ruijie(config-profile)#permit
```

**Platform** N/A

**Description**

## 9.5 ipv6 mld snooping

Use this command to enable MLD Snooping and specify IVGL/SVGL/IVGL-SVGL mode.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping** { ivgl | svgl | ivgl-svgl }

**no ipv6 mld snooping** [ ivgl | svgl | ivgl-svgl ]

**default ipv6 mld snooping** [ ivgl | svgl | ivgl-svgl ]

| Parameter Description | Parameter        | Description                             |
|-----------------------|------------------|-----------------------------------------|
|                       | <b>ivgl</b>      | MLD Snooping is running IVGL mode.      |
|                       | <b>svgl</b>      | MLD Snooping is running SVGL mode.      |
|                       | <b>ivgl-svgl</b> | MLD Snooping is running IVGL-SVGL mode. |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide**

- In IVGL mode, multicast flow in each VLAN is independent. The host only requests multicast flow from the routing interface within the same VLAN. The device forwards the multicast flow from any VLAN to the member port within the same VLAN.
- In SVGL mode, multicast flow is shared among VLANs. The host can request multicast flow across VLANs. Shared VLAN (VLAN 1 by default) should be specified. Only multicast flow from Shared VLAN can be forwarded to all member ports within the group address range, which may belong to different VLANs. Profile is used to specify a group range for SVGL. Only multicast flow within this range can be forwarded across VLANs. The other multicast flow is discarded.
- In IVGL-SVGL mode, Profile is used to specify a group range for SVGL. Multicast flow within this range is in SVGL mode and the other multicast flow is in IVGL mode.
- IPv6 multicast packets cannot be forwarded through SuperVLAN.

**Configuration** The following example enables MLD Snooping IVGL mode.

**Examples** Ruijie(config)# ipv6 igmp snooping ivgl

The following example enables MLD Snooping SVGL mode and specifies the shared VLAN and SVGL group range as VLAN1 and profile1 respectively.

Ruijie(config)# ipv6 igmp snooping svgl

Ruijie(config)# ipv6 igmp snooping svgl profile 1

**Description**

## 9.6 ipv6 mld snooping dyn-mr-aging-time

Use this command to set the aging time of the dynamic multicast route port.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping dyn-mr-aging-time** *second*

**no ipv6 mld snooping dyn-mr-aging-time**

**default ipv6 mld snooping dyn-mr-aging-time**

| Parameter Description | Parameter     | Description                                                                                                   |
|-----------------------|---------------|---------------------------------------------------------------------------------------------------------------|
|                       | <i>second</i> | Sets the aging time of the dynamic multicast route port, in the range from 1 to 3,600 in the unit of seconds. |

**Defaults** The default is 300 seconds.

**Command** Global configuration mode.

**Mode**

**Usage Guide** The switch will remove the dynamic multicast router interface from the router interface list if it fails to receive the MLD general group query packets or the ipv6 PIM Hello packets within the aging timeout on this interface.

Use this command to change the aging time of the routing ports learned dynamically. If the aging time is too short, routing ports will be added and deleted frequently.

 By default, the dynamic learning of routing ports is enabled. If learning fails, use the **show run** command to check whether this function is enabled.

**Configuration** The following example sets the aging time of the dynamic multicast routing port to 100 seconds.

**Examples** Ruijie(config)# ipv6 mld snooping dyn-mr-aging-time 100

| Related Commands | Command | Description |
|------------------|---------|-------------|

**Description**

## 9.7 ipv6 mld snooping fast-leave enable

Use this command to enable the MLD Snooping fast-leave function.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping fast-leave enable**  
**no ipv6 mld snooping fast-leave enable**  
**default ipv6 mld snooping fast-leave enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode.

**Usage Guide** The interface fast leave is that when IPv6 MLD Leave packets sent from the host are received on an interface, the interface is removed from the outgoing interface list of the corresponding forwarding entry. Then, the switch will not forward the received IPv6 MLD specific group query packets to the interface.

If there is only one receiver connected with the interface, enable the interface fast leave function to save the bandwidth and resources.

**Configuration Examples** The following example enables mld snooping fast-leave.

```
Ruijie(config)# ipv6 mld snooping fast-leave
```

| Related<br>Commands | Command | Description |

**Platform Description** N/A

## 9.8 ipv6 mld snooping filter

Use this command to filter the specific multicast flows.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping filter** *profile-number*  
**no ipv6 mld snooping filter**  
**default ipv6 mld snooping filter**

| Parameter<br>Description | Parameter             | Description                                          |
|--------------------------|-----------------------|------------------------------------------------------|
|                          | <i>profile-number</i> | Sets the profile number in the range from 1 to 1024. |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** You can configure an MLD Profile on an interface. If the MLD Report packets are received on the interface, the layer-2 device will determine whether the multicast address to be joined the interface is within the allowed range of the MLD Profile. The specified profile must be created before using this command.

**Configuration** The following example associates profile1 with the interface GigabitEthernet 0/1.

**Examples**

```
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 mld snooping filter 1
```

**Related  
Commands**

| Command          | Description        |
|------------------|--------------------|
| ipv6 mld profile | Creates a profile. |

**Platform** N/A

**Description**

## 9.9 ipv6 mld snooping host-aging-time

Use this command to set the aging time of the dynamic member port.

Use the **no** form of this command to cancel this configuration.

Use the **default** form of this command to restore the default setting.

**ipv6 mld snooping host-aging-time** *seconds*

**no ipv6 mld snooping host-aging-time**

**default ipv6 mld snooping host-aging-time**

**Parameter  
Description**

| Parameter      | Description                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the aging time of the dynamic member port, in seconds, ranging from 1-65,536 in the unit of seconds. |

**Defaults** The default aging time of the dynamic member port is 260 seconds.

**Command** Global configuration mode

**Mode**

**Usage Guide** The switch will remove the dynamic multicast router interface from the router interface list if it fails to receive the MLD general group query packets or the IPv6 PIM Hello packets within the aging timeout on this interface.

When the MLD Snooping is enabled, the port that receives the MLD Report packet will learn to be a dynamic member port. The default aging time of such dynamic member port is 260 seconds. You can

use this command to adjust the aging time. This configuration takes effect after the port receives the the next Report packet. The aging time of the dynamic member port should be longer than the query interval.

**Configuration** The following example sets the aging time of the dynamic member port to 30 seconds:

**Examples**

```
Ruijie(config)# ipv6 mld snooping host-aging-time 30
```

**Description**

## 9.10 ipv6 mld snooping max-groups

Use this command to set the maximum group allowed to join the interface dynamically.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping max-groups** *number*

**no ipv6 mld snooping max-groups**

**default ipv6 mld snooping max-groups**

**Parameter  
Description**

| Parameter     | Description                                         |
|---------------|-----------------------------------------------------|
| <i>number</i> | The number of groups, in the range from 0 to 65,536 |

**Defaults** The default is 65,536.

**Command** Interface configuration mode

**Mode**

**Usage Guide** With this command configured, when the group number exceeds the specified range on the interface, the switch will not receive and deal with the MLD Report packets.

The multicast groups are counted based on VLANs of an interface. If the interface has 3 VLANs, the counting result is 3 instead of 1 when an FF15::100 multicast request is received by all the VLAN.

**Configuration** The following example sets the maximum 100 multicast group on the interface GigabitEthernet 0/1.

**Examples**

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 mld snooping max-groups 100
```

|---------------------------------|-----------------------------------------------|
| <b>ipv6 mld snooping filter</b> | Filters the multicast group on the interface. |

**Platform** N/A  
**Description**

## 9.11 Ipv6 mld snooping mrouter learn

Use this command to enable the switch to dynamically learn MLD query or PIM packets to identify the mrouter interface automatically.

Use the **no** form of this command to disable this function.

Use the **default** form of this command to restore the default setting.

**ipv6 mld snooping [ vlan *vid* ] mrouter learn**

**no ipv6 mld snooping [ vlan *vid* ] mrouter learn**

**default ipv6 mld snooping [ vlan *vid* ] mrouter learn**

| Parameter Description | Parameter       | Description                          |
|-----------------------|-----------------|--------------------------------------|
|                       | vlan <i>vid</i> | VLAN ID, in the range from 1 to 4094 |

**Defaults** This function is enabled by default.

**Command Mode** Global configuration mode

**Usage Guide** The routing interface is the interface of the multicast device connected with the peer device. By default, the dynamically learned routing interface is enabled on the layer-2 multicast device. Use the **no** option to disable this function and clear all dynamically-learned routing interfaces.

 With the source port check enabled, only the multicast flow through the mroute interface are valid and forwarded to the registered interface on the layer-2 multicast device. Those multicast flow through the non-mroute interface are invalid and will be discarded.

**Configuration Examples** The following example enables the dynamic multicast routing port learning function for VLAN1.

```
Ruijie(config)# no ipv6 mld snooping mrouter learn
Ruijie(config)# ipv6 mld snooping vlan 1 mrouter learn
```

**Related Commands** N/A

## 9.12 ipv6 mld snooping query-max-response-time

Use this command to set the maximum response time of the MLD general query packet.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping query-max-response-time *seconds***

**no ipv6 mld snooping query-max-response-time**

**default ipv6 mld snooping query-max-response-time**

| Parameter Description | Parameter      | Description                                                                                                          |
|-----------------------|----------------|----------------------------------------------------------------------------------------------------------------------|
|                       | <i>seconds</i> | Sets the maximum response time of the MLD general query packet in the range from 1 to 65,535 in the unit of seconds. |

**Defaults** The default is 10 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Upon receiving the MLD general query packets, the Layer-2 multicast device updates the aging timer of all member ports. The time of the timer is the longest response value. When the timer value decreases to 0, it indicates that there is no member receiving the multicast flow on the interface, and the Layer-2 device removes this interface from the MLD Snooping forwarding list.

Upon receiving the MLD specific group query packets, the Layer-2 multicast device enables the aging timer of all member ports in this specific group. The time of the timer is the longest response value. When the timer value decreases to 0, it indicates that there is no member receiving the multicast flow on the interface, and the Layer-2 device removes this interface from the MLD Snooping forwarding list.

For the source query packets of the MLD specific group, the timer is not updated.

The configured maximum response time is effective after another query packet is received.

**Configuration Examples** The following example sets the maximum response time of the MLD general query packet to 100 seconds.

```
Ruijie(config)# ipv6 mld snooping query-max-response-time 100
```

| Related Commands | Command | Description |
|------------------|---------|-------------|

**Platform Description** N/A

## 9.13 ipv6 mld snooping source-check port

Use this command to enable the MLD source-check port.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping source-check port**

**no ipv6 mld snooping source-check port**

**default ipv6 mld snooping source-check port**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** The source-check port is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** The MLD Snooping source port check function is to limit the MLD multicast flow through the interace strictly. With the source port check disabled, all video flow are illegal and forwarded to the registered member port according to the MLD Snooping forwarding list. With the MLD Snooping source port check enabled, only the mulitcast flow through the mroute interface is legal and forwarded to the registered interface by the layer-2 multicast device; and the multicast flow through the non-mroute interface are illegal and discarded.

This command is used to enabled the source port check globally. Once this function is enabld, all multicast flow must come from the mroute interface, or they'll be discarded.

**Configuration** The following example enables MLD Snooping source-check port.

**Examples** Ruijie(config)# ipv6 mld snooping source-check port

| Related<br>Commands | Command | Description |

## 9.14 ipv6 mld snooping suppression enable

Use this command to enable the MLD Snooping suppression.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping suppression enable**

**no ipv6 mld snooping suppression enable**

**default ipv6 mld snooping suppression enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** The MLD Snooping suppression function is disabled by default.

**Command Mode** Global configuration mode.

**Usage Guide** With the IPv6 MLD Snooping suppression function enabled, within the query interval, the layer-2 device will only forward the first received MLD Report packet in an IPv6 multicast group to the layer-3 device, but not the other MLD Report packets in the same IPv6 multicast group, reducing the packet number in the network.

This command is used to enable the IPv6 MLD Snooping suppression, and only the MLDv1 Report packets are suppressed rather than the MLDv2 Report packets.

**Configuration** The following example enables MLD Snooping suppression.

**Examples**

```
Ruijie(config)# ipv6 mld snooping suppression enable
```

| Related Commands | Command | Description |

**Description**

## 9.15 ipv6 mld snooping svgl profile

Use this command to specify the group address range to be in the SVGL mode.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping svgl profile** *profile-number*

**no ipv6 mld snooping svgl profile**

**default ipv6 mld snooping svgl profile**

| Parameter Description | Parameter             | Description |
|-----------------------|-----------------------|-------------|
|                       | <i>profile-number</i> |             |

**Defaults** No profiles are associated with SVGL by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** With the SVGL mode or IVGL-SVGL mode configured for the MLD Snooping working mode, a profile shall be associated with the IVGL for the purpose of specifying the group address range in the SVGL mode. That is to say, the member port of the multicast forwarding entry can be forwarded across the VLANs, while the member ports of the corresponding multicast forwarding entries within other multicast address range must belong to the same VLAN. By default, no profile is associated, which means that apply no multicast group in the SVGL mode.

**Configuration Examples** The following example specifies the SVGL mode application range as the profile 2 group address range.

```
Ruijie(config)# ipv6 mld snooping svgl profile 2
```

| Related Commands | Command                            | Description                                          |
|------------------|------------------------------------|------------------------------------------------------|

|                  | <b>ipv6 mld snooping ivgl-svgl</b> | Enables the MLD Snooping and set the ivgl-svgl mode. |

**Platform** N/A

**Description**

## 9.16 ipv6 mld snooping svgl vlan

Use this command to specify the shared VLAN in MLD Snooping SVGL mode.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping svgl vlan** *vid*

**no ipv6 mld snooping svgl vlan**

**default ipv6 mld snooping svgl vlan**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | <i>vid</i>  |

**Defaults** The default is 1.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to specify the SVGL shared VLAN if MLD Snooping is running in SVGL or IVGL-SVGL mode.

**Configuration Examples** The following example sets the shared VLAN in MLD Snooping SVGL mode to 5.

```
Ruijie(config)# ipv6 mld snooping svgl vlan 5
```

| Related Commands | Command | Description |

## 9.17 ipv6 mld snooping vlan

Use this command to enable the MLD Snooping function for the specified VLAN.

Use the **no** form of this command to disable this function.

Use the **default** form of this command to restore the default setting.

**ipv6 mld snooping vlan** *vid*

**no ipv6 mld snooping vlan** *vid*

**default ipv6 mld snooping vlan** *vid*

| Parameter Description | Parameter  | Description                           |
|-----------------------|------------|---------------------------------------|
|                       | <i>vid</i> | VLAN ID, in the range from 1 to 4094. |

**Defaults** The MLD Snooping function is enabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** By default, the MLD Snooping is enabled in all VLANs. You can disable the MLD Snooping for the specified VLAN.

**Configuration** The following example disables the MLD Snooping function in VLAN 2 in IVGL mode.

**Examples**

```
Ruijie(config)# ipv6 mld snooping ivgl
Ruijie(config)# no ipv6 mld snooping vlan 2
```

| Related Commands | Command | Description |

## 9.18 ipv6 mld snooping vlan mrouter interface

Use this command to set the static mrouter interface.

Use the **no** or **default** form of this command to restore the default setting.

**ipv6 mld snooping vlan** *vid mrouter interface interface-type interface-number*

**no ipv6 mld snooping vlan** *vid mrouter interface interface-type interface-number*

**default ipv6 mld snooping vlan** *vid mrouter interface interface-type interface-number*

| Parameter Description | Parameter  | Description                           |
|-----------------------|------------|---------------------------------------|
|                       | <i>vid</i> | VLAN ID, in the range from 1 to 4094. |

|                                                  |                      |
|--------------------------------------------------|----------------------|
| <i>interface-type</i><br><i>interface-number</i> | The interface number |
|--------------------------------------------------|----------------------|

**Defaults** No static mrouter interface is configured by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** Use this command to set the static mrouter interface for the purpose that all IPv6 multicast data received on the switch can be forwarded. With the source port check function enabled, only the multicast flow through the mroute interface can be forwarded.

**Configuration** The following example sets a multicast routing port.

**Examples** Ruijie(config)# ipv6 mld snooping vlan 1 mrouter interface gigabitEthernet 0/1

| Related Commands | Command                                    | Description                           |

**Description**

## 9.19 ipv6 mld snooping vlan static interface

Use this command to set a static member port to receive the multicast flow for the purpose of preventing the port from being influenced by the MLD Report packets with the MLD Snooping enabled.

Uses the **no** form of this command to restore the default setting.

**ipv6 mld snooping vlan** *vid* **static** *group-address* **interface** *interface-type* *interface-number*

**no ipv6 mld snooping vlan** *vid* **static** *group-address* **interface** *interface-type* *interface-number*

| Parameter Description                            | Parameter             | Description                                             |
|--------------------------------------------------|-----------------------|---------------------------------------------------------|
|                                                  | <i>vid</i>            | VLAN ID, in the range from 1 to 4094. The default is 1. |
| <i>group-address</i>                             | The multicast address |                                                         |
| <i>interface-type</i><br><i>interface-number</i> | The interface number  |                                                         |

**Defaults** No static member port is configured by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** Use this command to set the interface as the member port of multiple static multicast addresses.

**Configuration** The following example sets the interface gigabitEthernet 0/1 as the static member port of the FF88::1 group.

**Examples**

```
Ruijie(config)# ipv6 mld snooping vlan 1 static FF88::1 interface
gigabitEthernet 0/1
```

**Related Commands**

**Description**

## 9.20 permit

Use this command to allow the multicast flow profile within the specified range in the profile configuration mode.

**permit**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The default profile action is **deny**.

**Command Mode** Profile configuration mode

**Usage Guide** Before configuring this command, use the **range** command to set the multicast range first.

**Configuration Examples** The following example allows the multicast flow profile within the range from FF15::1 to FF15::100 to be forwarded only.

```
Ruijie(config)# ipv6 mld snooping profile 1
Ruijie(config-profile)# range FF15::1 FF15::100
Ruijie(config-profile)# permit
```

**Related Commands**

| Command                 | Description                       |
|-------------------------|-----------------------------------|
| <b>ipv6 mld profile</b> | Creates one profile.              |
| <b>range</b>            | Sets the multicast address range. |
| <b>deny</b>             | Sets the profile action deny.     |

**Platform** N/A

**Description**

## 9.21 range

Use this command to specify the profile multicast flow range, which can be one single multicast address, or can be the multicast address within the specified range when configuring a profile in the profile configuration mode.

**range** *low-ipv6-address* [ *high-ip-address* ]

| Parameter Description | Parameter              | Description                                 |
|-----------------------|------------------------|---------------------------------------------|
|                       | <i>low-ip-address</i>  | The low address within the specified range  |
|                       | <i>high-ip-address</i> | The high address within the specified range |

**Defaults** No range is defined by default.

**Command Mode** Profile configuration mode

**Usage Guide** The value of *low-ipv6-address* shall be smaller than the one of *high-ipv6-address*. With the address range configured, an action shall be specified, and the default profile action is deny.

**Configuration Examples** The following example creates the multicast flow profile within the range from FF15::1 to FF15::100.

```
Ruijie(config)# ipv6 mld snooping profile 1
Ruijie(config-profile)# range FF15::1 FF15::100
Ruijie(config-profile)# permit
```

| Related Commands | Command                 | Description                     |

**Platform** N/A

**Description**

## 9.22 show ipv6 mld profile

Use this command to display the related MLD profile configuration.

**show ipv6 mld profile** *profile-number*

| Parameter Description | Parameter             | Description                                |
|-----------------------|-----------------------|--------------------------------------------|
|                       | <i>profile-number</i> | Profile number in the range from 1 to 1024 |

- Defaults** N/A
- Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode
- Usage Guide** Use this command to display the related MLD profile configuration.
- Configuration** The following example displays the MLD profile configuration.

**Examples**

```
Ruijie# show ipv6 mld profile
ipv6 mld profile    1
  permit
  range FF15::1 FF15::100

ipv6 mld profile    2
  deny
  range FF88::1 FF88::100
```

## 9.23 show ipv6 mld snooping

Use this command to display the related MLD Snooping information.

**show ipv6 mld snooping** [**gda-table** | **interfaces** *interface-type interface-number* | **mrouter** | **statistics** [**vlan** *vid*] | **vlan** *vid*]

**Parameter Description**

| Parameter                                                | Description                                                  |
|----------------------------------------------------------|--------------------------------------------------------------|
| <b>gda-table</b>                                         | Displays the multicast forwarding rule table.                |
| <b>Interfaces</b> <i>interface-type interface-number</i> | Displays the MLD Snooping filtering configuration.           |
| <b>mrouter</b>                                           | Displays the information about mrouter interface.            |
| <b>statistics</b>                                        | Displays the MLD Snooping statistics.                        |
| <b>vlan</b> <i>vlan-id</i>                               | Displays the MLD Snooping information of the specified vlan. |

- Defaults** N/A
- Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** Use this command to display the related MLD Snooping information.

**Configuration** The following example displays the MLD Snooping configurations.

**Examples**

```
In IVGL mode:
Ruijie#show ipv6 mld snooping
MLD-snooping mode: IVGL
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)

vlan 1
-----
MLD Snooping state: Enabled
Multicast router learning mode: Enable
MLD Fast-Leave: Enabled
MLD VLAN Mode: STATIC

In SVGL mode:
Ruijie#show ipv6 mld snooping
MLD-snooping mode: SVGL
SVGL vlan: 1
SVGL profile number: 1
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)

In IVGL-SVGL mode:
Ruijie#show ipv6 mld snooping
MLD-snooping mode: IVGL-SVGL
SVGL vlan: 1
SVGL profile number: 1
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Response Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
```

```
vlan 1
-----
MLD Snooping state: Enabled
Multicast router learning mode: Enable
MLD Fast-Leave: Enabled
MLD VLAN Mode: STATIC
```

## 10 MSDP Commands

### 10.1 clear ip msdp peer

Use this command to clear specific MSDP peer. This will clear the connection to the MSDP peer and then reestablish the connection to MSDP peer. The statistics of MSDP peer will be cleared at the same time.

**clear ip msdp peer** *peer-address*

| Parameter Description | Parameter           | Description                 |
|-----------------------|---------------------|-----------------------------|
|                       | <i>peer-address</i> | IP address of the MSDP peer |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to clear the TCP connection to the specified MSDP peer and clear all the MSDP peer statistics.

**Configuration Examples** The following example clears MSDP peer of 218.14.5.23.

```
Ruijie# clear ip msdp peer 218.14.5.23
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** This command is supported only on L3 devices.

### 10.2 clear ip msdp sa-cache

Use this command to clear SA cache entries.

**clear ip msdp sa-cache** [ *group-address* ]

| Parameter Description | Parameter            | Description   |
|-----------------------|----------------------|---------------|
|                       | <i>group-address</i> | Group address |

**Defaults** N/A

**Command** Privileged EXEC mode  
**Mode**

**Usage Guide** Use this command to clear the SA cache entries learned from MSDP peer. If no multicast group address is specified, all SA cache entries will be cleared.  
 After SA cache entries are cleared, the MSDP device will need to relearn SA messages.

**Configuration** The following example clears the SA cache entries with the multicast group 224.1.1.1.

**Examples**

```
Ruijie# clear ip msdp sa-cache 224.1.1.1
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** This command is supported only on L3 devices.  
**Description**

### 10.3 clear ip msdp statistics

Use this command to clear the statistics of MSDP peers without resetting the TCP sessions.

**clear ip msdp statistics** [ *peer-address* ]

| Parameter Description | Parameter           | Description                                                                                             |
|-----------------------|---------------------|---------------------------------------------------------------------------------------------------------|
|                       | <i>peer-address</i> | IP address of MSDP peer whose statistics counters, reset count, and input/output count will be cleared. |

**Defaults** N/A

**Command** Privileged EXEC mode  
**Mode**

**Usage Guide** Use this command to clear the statistics of MSDP peers and view the new statistics of MSDP peers.  
 This command can clear the statistics of one or more MDSP peers without resetting the MSDP peer.

**Configuration** The following example clears the statistics of the MSDP peer with IP address being 61.83.1.52.

**Examples**

```
Ruijie# clear ip msdp statistics 61.83.1.52
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.4 ip msdp default-peer

Use this command to define a default MSDP peer.

Use **no** or **default** form of this command to restore the default setting.

**ip msdp default-peer** *peer-address* [ **prefix-list** *prefix-list-name* ]

**no ip msdp default-peer** *peer-address*

**default ip msdp default-peer** *peer-address*

| Parameter Description | Parameter                                  | Description                    |
|-----------------------|--------------------------------------------|--------------------------------|
|                       | <i>peer-address</i>                        | IP address of the MSDP peer    |
|                       | <b>prefix-list</b> <i>prefix-list-name</i> | Specifies the BGP prefix list. |

**Defaults** By default, no default MSDP peer is configured.

**Command** Global configuration mode

**Mode**

**Usage Guide** The RPF-Peer calculation rule for the specified RP address may leads the loss of RPF-Peer information, which causes that the SA messages are dropped directly without the Peer-RPF check. With a default peer configured, the SA messages are ensured to pass the Peer-RFP check, so that the local host could accept the SA messages to learn the multicast source information carried by the SA messages.

If "prefix-list prefix-list-name" is not specified, all SA messages from the default MSDP peer will be accepted.

If "prefix-list prefix-list-name" is specified, only the SA messages from the RP specified by prefix-list prefix-list-name will be accepted.

If "prefix-list prefix-list-name" is specified but the prefix list is not configured, all SA messages from this default MSDP peer will be accepted.

**Configuration** The following example configures 172.16.33.1 as the default peer.

**Examples**

```
Ruijie(config)# ip msdp peer 172.16.33.1
Ruijie(config)# ip msdp peer 172.16.34.2
Ruijie(config)# ip msdp default-peer 172.16.33.1
```

| Related Commands | Command             | Description        |
|------------------|---------------------|--------------------|
|                  | <b>ip msdp peer</b> | Creates MSDP peer. |

**Platform** This command is supported only on layer-3 device.

**Description**

## 10.5 ip msdp description

Use this command to add descriptive information for MSDP peer.

Use **no** or **default** form of this command to restore the default setting.

**ip msdp description** *peer-address text*

**no ip msdp description** *peer-address*

**default ip msdp description** *peer-address*

| Parameter Description | Parameter           | Description                           |
|-----------------------|---------------------|---------------------------------------|
|                       | <i>peer-address</i> | IP address of the MSDP peer           |
|                       | <i>text</i>         | Descriptive information for MSDP peer |

**Defaults** No descriptive information is configured for MSDP peer.

**Command** Global configuration mode

**Mode**

**Usage Guide** The administrator can configure descriptive information for MSDP peers in order to identify them conveniently.

If the descriptive information A is specified for an MSDP peer, A is displayed. If no descriptive information is specified, "No description" is displayed.

**Configuration Examples** The following example configures the descriptive information for peer 172.17.1.2 as "customer-a".

```
Ruijie(config)# ip msdp description 172.171.1.2 customer-a
```

| Related Commands | Command                  | Description                                         |
|------------------|--------------------------|-----------------------------------------------------|
|                  | <b>show ip msdp peer</b> | Displays the descriptive information for MSDP peer. |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.6 ip msdp filter-sa-request

Use this command to filter the SA request messages sent from MSDP peer.

Use the **no** or **default** form of this command to restore the default setting.

**ip msdp filter-sa-request** *peer-address [ list access-list ]*

**no ip msdp filter-sa-request** *peer-address*

**default ip msdp filter-sa-request** *peer-address*

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

| Description                    |                                                                                   |
|--------------------------------|-----------------------------------------------------------------------------------|
| <i>peer-address</i>            | IP address of the MSDP peer                                                       |
| <b>list</b> <i>access-list</i> | The standard IP access list number or name for limiting multicast group addresses |

**Defaults** All SA request messages from MSDP peer will be accepted and replied.

**Command** Global configuration mode

**Mode**

**Usage Guide** Use this command to control which SA request messages will be accepted and replied.  
 If no access list is specified, all SA request messages will be ignored.  
 If a null access list is specified, all SA request messages will be ignored.  
 If an access list is specified, only the SA request messages from the multicast group permitted by the access list will be accepted, and other messages will be ignored.

**Configuration Examples** The following example configures to filter SA request messages from peer 172.16.223.1 and only accept SA request messages with group address falling within 224.0.1.0-224.0.1.255.

```
Ruijie(config)# ip msdp filter-sa-request 172.16.223.1 list 1
Ruijie(config)# access-list 1 permit 224.0.1.1 0.0.0.255
```

| Related Commands | Command             | Description        |
|------------------|---------------------|--------------------|
|                  | <b>ip msdp peer</b> | Creates MSDP peer. |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.7 ip msdp mesh-group

Use this command to configure a MSDP peer to be a member of a mesh group.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default settings.

**ip msdp mesh-group** *mesh-name* *peer-address*

**no ip msdp mesh-group** *mesh-name* *peer-address*

**default ip msdp mesh-group** *mesh-name* *peer-address*

| Parameter Description | Parameter                                                 | Description                        |
|-----------------------|-----------------------------------------------------------|------------------------------------|
|                       | <i>mesh-name</i>                                          | Name of mesh group, case sensitive |
| <i>peer-address</i>   | IP address of the MSDP peer to be a member of mesh group. |                                    |

**Defaults** No mesh group will be created, and MSDP peers do not belong to any mesh group.

**Command** Global configuration mode  
**Mode**

**Usage Guide** All MSDP peers in the mesh group shall be fully meshed, namely MSDP peer relationship has been established between every two members in the mesh group.  
The SA received by one member of the mesh group won't be forwarded to other members in the same mesh group, thus reducing SA flooding and simplify Peer-RPF forwarding.

**Configuration Examples** The following example configures MSDP peer at address 192.168.1.3 to be a member of the mesh group named "msdp-mesh".

```
Ruijie(config)# ip msdp mesh-group msdp-mesh 192.168.1.3
```

**Related Commands**

| Command                        | Description                             |
|--------------------------------|-----------------------------------------|
| <b>show ip msdp mesh-group</b> | Displays the information of mesh group. |

**Platform** This command is supported only on L3 devices.  
**Description**

## 10.8 ip msdp originator-id

Use this command to allow a speaker that originates a SA message to use the IP address of the interface as the originator address in the SA message.

Use the **no** form of this command to remove this configuration.

Use the **default** form of this command to restore the default setting.

**ip msdp originator-id** *interface-type* *interface-number*

**no ip msdp originator-id**

**default ip msdp originator-id**

**Parameter Description**

| Parameter               | Description      |
|-------------------------|------------------|
| <i>interface-type</i>   | Interface type   |
| <i>interface-number</i> | Interface number |

**Defaults** By default, the originator address in SA messages will be the RP address configured by PIM.

**Command** Global configuration mode  
**Mode**

**Usage Guide** The master IP address of this interface will be used as the originator address in the SA messages. If no IP address is configured for this interface, or the interface is shut down, then the originator address in the SA messages won't use the master IP address of this interface, but use the RP address configured by PIM.  
Under certain circumstances, you may expect to change the originator address in SA messages,

such as during Anycast-RP deployment. By this time, you can use this command to modify the originator address in SA messages.

**Configuration** The following example uses the IP address of Loopback0 as the RP address in SA messages.

**Examples**

```
Ruijie(config)# ip msdp originator-id loopback0
```

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.9 ip msdp password

Use this command to enable MD5 encryption of the TCP connection between MSDP peers.

Use the **no** or **default** form of this command to restore the default setting.

**ip msdp password peer** *peer-address* [ *encryption-type* ] *string*

**no ip msdp password peer** *peer-address*

**default ip msdp password peer** *peer-address*

**Parameter  
Description**

| Parameter              | Description                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>peer-address</i>    | IP address of MSDP peer                                                                                                                                        |
| <i>encryption-type</i> | Grade of password: 0 (lowest level)-7 (highest level). Currently, only 0 and 7 are supported. The default encryption type is 0.                                |
| <i>string</i>          | The password used for TCP MD5 authentication.<br>Range: up to 80 characters when the encryption type is 0; up to 160 characters when the encryption type is 7. |

**Defaults** MD5 encryption of the TCP connection between MSDP peers is disabled.

**Command** Global configuration mode

**Mode**

**Usage Guide** When it is needed to authenticate the MSDP peers, you can enable MD5 encryption of TCP connection between MSDP peers. In such a case, two interconnected MSDP peers must be configured with MD5 authentication with same password, or else the connection will fail. If the password is configured or changed, the local MSDP device won't terminate the current session, but will try to use the new password to maintain the current session until timeout. If you have configure the password locally for the MSDP peer but no password is configured on MSDP, the following warning message will be displayed on the console:

```
%TCP-6-BADAUTH: MD5 digest NOT expected but found (200.200.200.6,
39996) -> (200.200.200.16, 639)
```

If different MD5 passwords are configured between MSDP peers, the following warning message will be displayed on the console:

```
%TCP-6-BADAUTH: MD5 digest failed for (200.200.200.6,
12302) -> (200.200.200.16, 639)
```

 If the encryption type is 0, the encryption key for TCP is the string entered in the console. That is, this type of encryption is supported when Ruijie Networks MSDP devices communicates with those from other vendors. Thus, this encryption type is recommended for mutual communication between devices from different vendors.

 If the encryption type is 7, the entered encryption key must be even and not less than 4. Different from type 0, the encryption key is not the string entered in the console. Instead, it is a new string computed by Ruijie-defined algorithm. In addition, our algorithm is different from other private vendor-specific algorithms. Therefore, this encryption type is supported only when Ruijie Networks devices are mutually connected.

**Configuration** The following example configures the MD5 password of "test" for the MSDP peer of 10.32.43.144.

**Examples**

```
Ruijie(config)# ip msdp password peer 10.32.43.144 0 test
```

**Related  
Commands**

**Description**

## 10.10 ip msdp peer connect-source

Use this command to create MSDP peer.

Use **no** or **default** form of this command to remove MSDP peer.

**ip msdp peer** *peer-address* **connect-source** *interface-type interface-number*

**no ip msdp peer** *peer-address*

**default ip msdp peer** *peer-address*

**Parameter  
Description**

| Parameter                                        | Description                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>peer-address</i>                              | IP address of MSDP peer<br>The peer MSDP device uses this address to communicate with the local MSDP device for TCP connection.                                                                                                                                                                                                                  |
| <i>interface-type</i><br><i>interface-number</i> | Interface type and interface number.<br>The local MSDP device uses the main address of this interface as the source IP for the TCP connection to the remote MSDP peer.<br>Loopback interface is recommended.<br>If no IP address is configured for this interface, or the interface is shut down, then MSDP peer relation cannot be established. |

**Defaults** No MSDP peer is created.

**Command Mode** Global configuration mode

**Usage Guide** To enable MSDP, MSDP peer must be created.

**Configuration Examples** The following example configures the main address of interface loopback 0 as the source address for establishing MSDP peer relation with 192.168.5.1.

```
Ruijie(config)# ip msdp peer 192.168.5.1 connect-source loopback 0
```

**Related Commands**

| Command                  | Description                               |
|--------------------------|-------------------------------------------|
| <b>show ip msdp peer</b> | Displays the information about MSDP peer. |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.11 ip msdp redistribute

Use this command to configure which (S, G) entries from the multicast routing table can be advertised to MSDP peers.

Use the **no** form of this command to remove this configuration.

Use the **default** form of this command to restore the default settings.

**ip msdp redistribute** [ **list** *access-list-name* ] [ **route-map** *route-map* ]

**no ip msdp redistribute**

**default ip msdp redistribute**

**Parameter Description**

| Parameter                           | Description                                                                                                 |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>list</b> <i>access-list-name</i> | Number or name of an extended IP access list that controls which multicast routes (S, G) can be advertised. |
| <b>route-map</b> <i>route-map</i>   | Defines route-map.                                                                                          |

**Defaults** All multicast sources (S, G) registered on the local RP will be advertised.

**Command Mode** Global configuration mode

**Usage Guide** After redistribution filtering is configured, the (S, G) information from the local AS or the other AS can be added to the MSDP only through redistribution filtering.

If "**list** *access-list-name*" is specified, only those matched multicast routes (S, G) will be advertised.

If "**route-map** *map-name*" is specified, only multicast routes (S, G) matching the criteria given in "*map-name*" will be advertised.

If two keywords are specified, then multicast routes (S, G) matching all conditions will be advertised.

If the "**ip msdp redistribute**" command is configured with no keywords, no multicast sources will be advertised.

**Configuration** The following example configures to only advertise multicast routes with multicast source being 200.200.200.0/24 and group address being 225.1.1.0/24.

**Examples**

```
Router(config)# ip msdp redistribute list 100
Router(config)# ip access-list extended 100
Router(config-ext-nacl)# permit ip 200.200.200.0 0.0.0.255 225.1.1.0
0.0.0.255
```

**Related  
Commands**

| Command                      | Description                                     |
|------------------------------|-------------------------------------------------|
| <b>ip msdp sa-filter in</b>  | Configures the incoming filter for SA messages. |
| <b>ip msdp sa-filter out</b> | Configures the outgoing filter for SA messages. |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.12 ip msdp sa-filter in

Use this command to configure an incoming filter for SA messages.

Use the **no** or **default** form of this command to remove the incoming filter.

**ip msdp sa-filter in** *peer-address* [ **list** *access-list* ] [ **route-map** *route-map* ] [ **rp-list** *rp-access-list* ]  
[ **rp-route-map** *rp-route-map* ]

**no ip msdp sa-filter in** *peer-address*

**default ip msdp sa-filter in** *peer-address*

**Parameter  
Description**

| Parameter                               | Description                                                                                                          |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <i>peer-address</i>                     | IP address of MSDP peer                                                                                              |
| <b>list</b> <i>access-list</i>          | Number or name of an extended IP access list that controls which multicast routes (S, G) can be received.            |
| <b>route-map</b> <i>route-map</i>       | Specify the name of route-map; only SA messages matching the criteria given in " <i>map-name</i> " can pass through. |
| <b>rp-list</b> <i>rp-access-list</i>    | Number or name of standard access list that controls RPs.                                                            |
| <b>rp-route-map</b> <i>rp-route-map</i> | Specify the name of route map for RP; only the SA messages matching <i>rp-map-name</i> can be accepted.              |

**Defaults** All incoming SA messages will be accepted without filtering.

**Command** Global configuration mode  
**Mode**

**Usage Guide** If the command is configured, but no access list or route map is specified, all incoming SA messages will be filtered.

If only the **list** keyword or the **route-map** keyword is used, the multicast source (S, G) in SA messages matching the criteria corresponding to this keyword will be accepted.

If only the **rp-list** keyword or the **rp-route-map** keyword is used, the SA message will be accepted if the RP address carried in SA message matches the criteria corresponding to this keyword.

If two or more keywords of **list**, **route-map**, **rp-list** and **rp-route-map** are used, the SA message will be accepted if any multicast source (S, G) in SA message meet the criteria corresponding to all keywords.

**Configuration** The following example configures that all SA messages from the peer of 10.234.1.43 will be filtered.

**Examples**

```
Ruijie(config)# ip msdp peer 10.234.1.43
Ruijie(config)# ip msdp sa-filter in 10.234.1.43
```

**Related Commands**

| Command                      | Description                                                              |
|------------------------------|--------------------------------------------------------------------------|
| <b>ip msdp peer</b>          | Configures MSDP peer.                                                    |
| <b>ip msdp sa-filter-out</b> | Configures the outgoing filter for SA messages received from MSDP peers. |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.13 ip msdp sa-filter out

Use this command to configure an outgoing filter for SA messages.

Use the **no** or **default** form of this command to remove the outgoing filter.

**ip msdp sa-filter out** *peer-address* [ **list** *access-list* ] [ **route-map** *route-map* ] [ **rp-list** *rp-access-list* ] [ **rp-route-map** *rp-route-map* ]

**no ip msdp sa-filter out** *peer-address*

**default ip msdp sa-filter out** *peer-address*

**Parameter Description**

| Parameter                               | Description                                                                                                 |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <i>peer-address</i>                     | IP address of MSDP peer                                                                                     |
| <b>list</b> <i>access-list</i>          | Number or name of an extended IP access list that controls which multicast routes (S, G) can be received.   |
| <b>route-map</b> <i>route-map</i>       | Specify the name of route-map; only SA messages matching the criteria given in "map-name" can pass through. |
| <b>rp-list</b> <i>rp-access-list</i>    | Number or name of standard access list that controls RPs.                                                   |
| <b>rp-route-map</b> <i>rp-route-map</i> | Specify the name of route map for RP; only the SA messages                                                  |

|                                       |
|---------------------------------------|
| matching rp-map-name can be accepted. |
|---------------------------------------|

**Defaults** All SA messages received will be forwarded to the MSDP peer.

**Command** Global configuration mode

**Mode**

**Usage Guide** If the command is configured, but no access list or route map is specified, all SA messages won't be forwarded to this MSDP peer.

If only one keyword of **list**, **route-map**, **rp-list** and **rp-route-map** is used, the multicast source pair (S, G) will be forwarded to this MSDP peer if the criteria corresponding to this keyword are met.

If two or more keywords of **list**, **route-map**, **rp-list** and **rp-route-map** are used, the (S, G) pair will only be forwarded to this MSDP peer if criteria corresponding to all keywords are met.

**Configuration Examples** The following example allows only multicast sources that pass access list 100 to be forwarded to the peer of 10.234.1.43.

```
Ruijie(config)# ip msdp peer 10.234.1.43
Ruijie(config)# ip msdp sa-filter out 10.234.1.43 list 100
Ruijie(config)# access-list 100 permit ip 10.211.0.0 0.0.255.255 224.12.0.0
0.0.255.255
```

**Related Commands**

| Command                     | Description                                                              |
|-----------------------------|--------------------------------------------------------------------------|
| <b>ip msdp peer</b>         | Configures MSDP peer.                                                    |
| <b>ip msdp sa-filter-in</b> | Configures the incoming filter for SA messages received from MSDP peers. |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.14 ip msdp sa-limit

Use this command to configure the allowable maximum number of Source-Active (SA) cache entries from a MSDP peer.

Use the **no** or **default** form of this command to restore the default settings.

**ip msdp sa-limit** *peer-address sa-limit*

**no ip msdp sa-limit** *peer-address*

**default ip msdp sa-limit** *peer-address*

**Parameter Description**

| Parameter           | Description                                                             |
|---------------------|-------------------------------------------------------------------------|
| <i>peer-address</i> | IP address of MSDP peer                                                 |
| <i>sa-limit</i>     | Maximum number of SA messages from an MSDP peer allowed in the SA cache |

**Defaults** The maximum number of SA messages from an MSDP peer allowed in the SA cache is not limited.

**Command Mode** Global configuration mode

**Usage Guide** It is suggested to configure this command on all MSDP peers to prevent SA flooding attacks from MSDP peers.  
When the local device has learned A (quantity) SA entries from an MSDP peer, and A is greater than B (the SA limit), the SA entries from this peer will not be cleared at once. Instead, the aging mechanism (no more than 135 seconds) will lower A to B. That is, this command is not effective immediately. It aims to saving effective multicast information best to raise networking productivity. If you want to clear the SA entries in such case, use the **clear ip msdp sa-cache** command.

**Configuration Examples** The following example configures the SA message limit to 100 for the MSDP peer with IP address being 172.16.3.1.

```
Ruijie(config)# ip msdp sa-limit 172.16.3.1 100
```

|---------|-------------|
| N/A     | N/A         |

**Platform Description** This command is supported only on L3 devices.

## 10.15 ip msdp shutdown

Use this command to shut down the connection to MSDP peer.

Use the **no** or **default** form of this command to restore the default settings.

**ip msdp shutdown** *peer-address*

**no ip msdp shutdown** *peer-address*

**default ip msdp shutdown** *peer-address*

**Parameter Description**

| Parameter           | Description                 |
|---------------------|-----------------------------|
| <i>peer-address</i> | IP address of the MSDP peer |

**Defaults** The connection to peer is not shut down.

**Command Mode** Global configuration mode

**Usage Guide** Only the TCP connection to the specified MSDP peer will be shut down. Neither the MSDP peer nor its configurations will be cleared.

**Configuration** The following example shuts down the MSDP peer at IP address 192.168.7.20.

**Examples** Ruijie(config)# **ip msdp shutdown** 192.168.7.20

**Related  
Commands**

| Command      | Description        |
|--------------|--------------------|
| ip msdp peer | Creates MSDP peer. |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.16 ip msdp timer

Use this command to configure the interval for timer re-connection.

Use the **no** or **default** form of this command to restore the default settings.

**ip msdp timer** *interval*

**no ip msdp time**

**default ip msdp timer**

**Parameter  
Description**

| Parameter       | Description                                                                            |
|-----------------|----------------------------------------------------------------------------------------|
| <i>interval</i> | Interval for timer re-connection, within the range from 1 to 60 in the unit of seconds |

**Defaults** The default interval is 30 seconds.

**Command  
Mode** Global configuration mode

**Usage Guide** By default, the interval for timer re-connection is 30 seconds, that is, the peer in active end can initiate only one TCP connection within 30 seconds. In certain applications, the interval is expected to be decreased in order to accelerate convergence of MSDP peering relation.

**Configuration** The following example sets the interval for timer re-connection to 20 seconds.

**Examples** Ruijie(config)# **ip msdp timer** 20

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform** This command is supported only on L3 devices.

**Description**

## 10.17 ip msdp ttl-threshold

Use this command to limit the TTL value of multicast data packets carried in SA messages in order to limit the transmission of multicast packets.

Use the **no** or **default** form of this command to restore to the default settings.

**ip msdp ttl-threshold** *peer-address* *tvl-value*

**no ip msdp ttl-threshold** *peer-address*

**default ip msdp ttl-threshold** *peer-address*

| Parameter Description | Parameter           | Description                          |
|-----------------------|---------------------|--------------------------------------|
|                       | <i>peer-address</i> | IP address of the MSDP peer          |
|                       | <i>tvl-value</i>    | TTL value in the range from 0 to 255 |

**Defaults** TTL threshold is 0 by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command limits multicast data packets which are sent in data-encapsulated SA messages. Only multicast packets with an IP-header TTL greater than or equal to the *tvl-value* will be sent to the MSDP peer. If the TTL value of multicast data is less than the threshold configured, then the multicast data will be separated from SA messages and discarded, and the SA messages without multicast data will be sent to the MSDP peer.

This command only limits the transmission of multicast data in SA messages without compromising the transmission of multicast sources in SA messages

**Configuration** The following example configures the TTL threshold for peer at IP address 192.168.10.1 to 8 hops:

**Examples** Ruijie(config)# **ip msdp ttl-threshold** 192.168.10.1 8

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Description**

## 10.18 ip msdp peer-limit

Use this command to set the upper limit of MSDP peers.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default settings.

**ip msdp peer-limit** *peer-limit*

**no ip msdp peer-limit**  
**default ip msdp peer-limit**

**Parameter  
Description**

| Parameter         | Description                                               |
|-------------------|-----------------------------------------------------------|
| <i>peer-limit</i> | The upper limit of MSDP peers, in the range from 1 to128. |

**Defaults** The default is 64.

**Command  
Mode** Global configuration mode

**Usage Guide** This command is used to set the upper limit of MSDP peers. If the number of existing MSDP peers exceeds the upper limit to be configured, you should delete some peers, or the configuration will fail.

**Configuration** The following example sets the upper limit of MSDP peers to 128.

**Examples** Ruijie(config)# ip msdp peer-limit 128

**Platform  
Description** This command is supported only on L3 devices.

## 10.19 ip msdp global-sa-limit

Use this command to configure the maximum SA cache.

Use the **no** form of this command to remove the configuration.

Use the **default** form of this command to restore the default settings.

**ip msdp global-sa-limit** *sa-limit*

**no ip msdp global-sa-limit** *sa-limit*

**default ip msdp global-sa-limit** *sa-limit*

**Parameter  
Description**

| Parameter       | Description                                       |
|-----------------|---------------------------------------------------|
| <i>sa-limit</i> | The maximum SA cache, in the range from1 to 4,096 |

**Defaults** The default SA cache is 1,024.

**Command  
Mode** Global configuration mode

**Usage Guide** This command is used to set the maximum SA cache. It's recommended to configure it at the beginning of startup.

When MSDP is running, the increase in maximum SA cache has no influence upon the previously learned entries; the decrease in maximum SA cache will clear all entries learned before and start

caching again.

**Configuration** The following example sets the maximum SA cache to 4,096.

**Examples** Ruijie(config)# ip msdp global-sa-limit 4096

**Platform**

This command is supported only on L3 devices.

**Description**

## 10.20 show ip msdp count

Use this command to display the number of sources and groups originated in SA messages and the number of SA messages from an MSDP peer in the SA cache.

**show ip msdp count** [ *as-number* ]

**Parameter  
Description**

| Parameter        | Description                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> | Displays the number of sources and groups originated in SA messages from the specified autonomous system number. |

**Defaults**

**Platform** This command is supported only on L3 devices.

#### Description

## 10.23 show ip msdp rpf-peer

Use this command to display the information about MSDP RPF peer corresponding to the specified originator address.

**show ip msdp rpf-peer** *ip-address*

#### Parameter Description

| Parameter         | Description                                 |
|-------------------|---------------------------------------------|
| <i>ip-address</i> | IP address of the originator of SA messages |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the rpf-peer information of RP at address 1.1.1.1:

```
Ruijie# sh ip msdp rpf-peer 1.1.1.1
RPF peer information for 1.1.1.1
RPF peer: 200.200.200.2
```

```
RPF rule: Peer is only active peer
RPF route/mask: Not-used
RPF type: Not-used
```

**Description**

## 10.24 show ip msdp sa-cache

Use this command to display (S, G) state learned.

**show ip msdp sa-cache** [ *group-address* | *source-address* ] [ *group-address* | *source-address* ]  
[ *as-number* ]

**Parameter  
Description**

| Parameter              | Description                                                                        |
|------------------------|------------------------------------------------------------------------------------|
| <i>group-address</i>   | Group address of the group or source about which (S, G) information is displayed   |
| <i>source -address</i> | Source address of the group or source about which (S, G) information is displayed. |
| <i>as-number</i>       | Autonomous system number generated by SA messages.                                 |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays (S, G) state learned.

**Examples**

```
Ruijie# sh ip msdp sa-cache
MSDP Source-Active Cache: 2 entries
MSDP Source-Active Cache: 2 entries
(200.200.200.200, 227.1.2.2), RP: 20.20.20.20, (M)BGP/AS 100,
04:17:09/00:02:05, Peer 200.200.200.2
Learned from peer 200.200.200.2, RPF peer 200.200.200.2,
SAs received: 277, Encapsulated data received: 0
(200.200.200.200, 227.1.2.3), RP: 20.20.20.20, (M)BGP/AS 100,

**Description**

## 10.25 show ip msdp sa-originated

Use this command to display the (S, G) information to be sent by the local device. The (S, G) information has passed redistribution filtering.

**show ip msdp sa-originated**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** This command can be used to display the (S, G) information sent by the local device that is the RP in PIM-SM with the multicast source (S, G) registered and is configured with MSDP peer. (S, G) information displayed has passed redistribution filtering, but, whether the information can be sent to the MSDP peer requires the results of egress filtering for the information.

**Configuration Examples** The following is sample output of "show ip msdp sa-originated" command.

```
Ruijie# sh ip msdp sa-originated
MSDP Source-Active Originated: 5 entries
(192.168.23.78, 225.0.0.1), RP: 192.168.23.249
(192.168.23.79, 225.0.0.2), RP: 192.168.23.249
(192.168.23.80, 225.0.0.3), RP: 192.168.23.249
```

```
(192.168.23.81, 225.0.0.4), RP: 192.168.23.249
(192.168.23.82, 225.0.0.5), RP: 192.168.23.249
```

| Field                      | Description                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------|
| (192.168.23.78, 225.0.0.1) | The source address (the first IP address) and group address (the second IP address) of SA to be sent. |
| RP 192.168.23.249          | RP address of SA sent.                                                                                |

#### Related Commands

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform** This command is only supported on L3 devices.

#### Description

## 10.26 show ip msdp summary

Use this command to display the summary information about all MSDP peers.

**show ip msdp summary**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** If the local device configured with MSDP peers is the PIM-SM Rendezvous Point (RP) and multicast sources (S,G) registers in the RP, the command will display: (S,G) to Send  
The displayed (S,G) have gone through redistribution filtering (command: **ip msdp redistribute**).  
However, whether these (S,G) will be delivered to MSDP peers successfully relies on the outgoing filter (command: **ip msdp sa-filter out**).

**Configuration Examples** The following example displays the summary information about all MSDP peers.

#### Examples

```
Ruijie# sh ip msdp summary

Msdp Peer Status Summary
Peer Address      As      State      Uptime/Downtime  Reset-Count
Sa-Count  Peer-description
200.200.200.2    100     Up         04:22:11         10         6616
No description
200.200.200.3    100     Down      19:17:13         4          0
```

`peer-A`

| Field           | Description                                      |
|-----------------|--------------------------------------------------|
| Peer Address    | IP address of MSDP peer                          |
| AS              | Autonomous system to which the MSDP peer belongs |
| State           | State of the MSDP peer                           |
| Uptime/Downtime | Up time or down time of MSDP peer                |

# 1 AAA Commands

## 1.1 aaa accounting commands

Use this command to configure NAS command accounting.

Use the **no** form of this command to restore the default setting.

**aaa accounting commands** *level* { **default** | *list-name* } **start-stop** *method1* [ *method2...* ]

**no aaa accounting commands** *level* { **default** | *list-name* }

| Parameter   | Parameter        | Description                                                                                                             |
|-------------|------------------|-------------------------------------------------------------------------------------------------------------------------|
| Description | <i>level</i>     | The accounting command level, 0-15. The message shall be recorded before which command level is executed is determined. |
|             | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for command accounting.    |
|             | <i>list-name</i> | Name of the command accounting method list, which could be any character strings.                                       |
|             | <i>method</i>    | It must be one of the keywords listed in the following table. One method list can contain up to four methods.           |
|             | <b>none</b>      | Does not perform accounting.                                                                                            |
|             | <b>group</b>     | Uses the server group for accounting, the TACACS+ server group is supported.                                            |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS enables the accounting command function after enabling the login authentication. After enabling the accounting function, it sends the command information to the security service. The configured accounting command method must be applied to the terminal line that needs accounting command; otherwise it is ineffective.

**Configuration** The following example enables NAS command accounting.

**Examples**

```
Ruijie(config)# aaa accounting commands 15 default start-stop group tacacs+
```

| Related Commands | Command                    | Description                                           |
|------------------|----------------------------|-------------------------------------------------------|
|                  | <b>aaa new-model</b>       | Enables the AAA security service.                     |
|                  | <b>aaa authentication</b>  | Defines AAA authentication.                           |
|                  | <b>accounting commands</b> | Applies the accounting commands to the terminal line. |

**Platform** N/A

**Description**

## 1.2 aaa accounting exec

Use this command to enable NAS access accounting.

Use the **no** form of this command to restore the default setting.

**aaa accounting exec** { **default** | *list-name* } **start-stop** *method1* [ *method2...*]

**no aaa accounting exec** { **default** | *list-name* }

| Parameter          | Parameter        | Description                                                                                                       |
|--------------------|------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for Exec accounting. |
|                    | <i>list-name</i> | Name of the Exec accounting method list, which could be any character strings                                     |
|                    | <i>method</i>    | It must be one of the keywords: <b>none</b> and <b>group</b> . One method list can contain up to four methods.    |
|                    | <b>none</b>      | Does not perform accounting.                                                                                      |
|                    | <b>group</b>     | Uses the server group for accounting, the RADIUS and TACACS+ server group is supported.                           |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** RGOS enables the exec accounting function after enabling the login authentication. After enabling the accounting function, it sends the account start information to the security server when the users log in the NAS CLI, and sends the account stop information to the security server when the users log out. If it does not send the account start information to the security server when a user logs in, it does not send the account stop information to the security server when a user logs out, either.

The configured exec accounting method must be applied to the terminal line that needs accounting command; otherwise it is ineffective.

**Configuration** The following example enables NAS access accounting.

**Examples**

```
Ruijie(config)# aaa accounting network start-stop group radius
```

| Related         | Command                    | Description                                       |

| <b>Commands</b> | <b>aaa new-model</b>       | Enables the AAA security service.                 |
|                 | <b>aaa authentication</b>  | Defines AAA authentication.                       |
|                 | <b>accounting commands</b> | Applies the Exec accounting to the terminal line. |

**Platform** N/A  
**Description**

### 1.3 aaa accounting network

Use this command to enable network access accounting.

Use the **no** form of this command to restore the default setting.

**aaa accounting network { default | list-name } start-stop method1 [ method2..]**

**no aaa accounting network { default | list-name }**

| Parameter          | Parameter        | Description                                                                                                                                                                                               |
|--------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for Network accounting.                                                                                      |
|                    | <i>list-name</i> | Name of the accounting method list                                                                                                                                                                        |
|                    | <i>method</i>    | Sends accounting messages at both the start time and the end time of access. Users are allowed to access the network, no matter whether the start accounting message enables the accounting successfully. |
|                    | <b>none</b>      | Does not perform accounting.                                                                                                                                                                              |
|                    | <b>group</b>     | Uses the server group for accounting, the RADIUS and TACACS+ server group is supported.                                                                                                                   |

**Defaults** This function is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** RGOS performs accounting of user activities by sending record attributes to the security server. Use the **start-stop** keyword to set the user accounting option.

**Configuration** The following example enables network access accounting.

**Examples**

```
Ruijie(config)# aaa accounting network start-stop group radius
```

| Related         | Command                          | Description                                  |
|-----------------|----------------------------------|----------------------------------------------|
| <b>Commands</b> | <b>aaa new-model</b>             | Enables the AAA security service.            |
|                 | <b>aaa authorization network</b> | Defines a network authorization method list. |
|                 | <b>aaa authentication</b>        | Defines AAA authentication.                  |
|                 | <b>username</b>                  | Defines a local user database.               |

**Platform** N/A  
**Description**

## 1.4 aaa accounting update

Use this command to enable the accounting update function.

Use the **no** form of this command to restore the default setting.

**aaa accounting update**

**no aaa accounting update**

**Parameter  
Description**

N/A

**Defaults**

This function is disabled by default.

**Command  
Mode**

Global configuration mode

**Usage Guide**

If the AAA security service is not enabled, the accounting update function cannot be used. This command is used to set the accounting interval if the AAA security service has been enabled.

**Configuration**

The following example enables the accounting update function.

**Examples**

```
Ruijie(config)# aaa new-model
Ruijie(config)# aaa accounting update
```

**Related  
Commands**

| Command                       | Description                               |
|-------------------------------|-------------------------------------------|
| <b>aaa new-model</b>          | Enables the AAA security service.         |
| <b>aaa accounting network</b> | Defines a network accounting method list. |

**Platform  
Description**

N/A

## 1.5 aaa accounting update periodic

Use this command to set the interval of sending the accounting update message.

Use the **no** form of this command to restore the default setting.

**aaa accounting update periodic** *interval*

**no aaa accounting update periodic**

**Parameter  
Description**

| Parameter       | Description                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------------------|
| <i>interval</i> | Interval of sending the accounting update message, in the unit of minutes. The shortest interval is 1 minute. |

**Defaults**

The default is 5 minutes.

**Command**

Global configuration mode

**Mode**

**Usage Guide** If the AAA security service is not enabled, the accounting update function cannot be used. This command is used to set the accounting interval if the AAA security service has been enabled.

**Configuration** The following example sets the interval of accounting update to 1 minute.

**Examples**

```
Ruijie(config)# aaa new-model
Ruijie(config)# aaa accounting update
Ruijie(config)# aaa accounting update periodic 1
```

**Related****Commands**

| Command                       | Description                               |
|-------------------------------|-------------------------------------------|
| <b>aaa new-model</b>          | Enables the AAA security service.         |
| <b>aaa accounting network</b> | Defines a network accounting method list. |

**Platform** N/A

**Description**

## 1.6 aaa authentication dot1x

Use this command to enable AAA authentication 802.1x and configure the 802.1x user authentication method list.

Use the **no** form of this command to delete the 802.1x user authentication method list.

**aaa authentication dot1x** { **default** | *list-name* } *method1* [ *method2...* ]

**no aaa authentication dot1x** { **default** | *list-name* }

**Parameter****Description**

| Parameter        | Description                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>default</b>   | When this parameter is used, the following defined 802.1x user authentication method list is used as the default method for user authentication. |
| <i>list-name</i> | Name of the 802.1x user authentication method list, which could be any character string                                                          |
| <i>method</i>    | It must be one of the keywords: <b>local</b> , <b>none</b> and <b>group</b> . One method list can contain up to four methods.                    |
| <b>local</b>     | Uses the local user name database for authentication.                                                                                            |
| <b>none</b>      | Does not perform authentication.                                                                                                                 |
| <b>group</b>     | Uses the server group for authentication. At present, the RADIUS server group is supported.                                                      |

**Defaults** N/A

**Command** Global configuration mode

**Mode**

**Usage Guide** If the AAA 802.1x security service is enabled on the device, users must use AAA for 802.1x user authentication negotiation. You must use the **aaa authentication dot1x** command to configure a default or optional method list for 802.1x user authentication.

The next method can be used for authentication only when the current method does not work.

**Configuration Examples** The following example defines an AAA authentication method list named **RDS\_D1X**. In the authentication method list, first the RADIUS security server is used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

```
Ruijie(config)# aaa authentication dot1x rds_d1x group radius local
```

**Description**

## 1.7 aaa authentication enable

Use this command to enable AAA Enable authentication and configure the Enable authentication method list.

Use the **no** form of this command to delete the user authentication method list.

**aaa authentication enable default** *method1* [*method2...*]

**no aaa authentication enable default**

| Parameter Description | Parameter      | Description                                                                                                                            |
|-----------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>default</b> | When this parameter is used, the following defined authentication method list is used as the default method for Enable authentication. |
|                       | <i>method</i>  | It must be one of the keywords: <b>local</b> , <b>none</b> and <b>group</b> . One method list can contain up to four methods.          |
|                       | <b>local</b>   | Uses the local user name database for authentication.                                                                                  |
|                       | <b>none</b>    | Does not perform authentication.                                                                                                       |
|                       | <b>group</b>   | Uses the server group for authentication. At present, the RADIUS and TACACS+ server groups are supported.                              |
|                       | <b>enable</b>  | Enables AAA Enable authentication.                                                                                                     |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** If the AAA Enable authentication service is enabled on the device, users must use AAA for Enable

authentication negotiation. You must use the **aaa authentication enable** command to configure a default or optional method list for Enable authentication.

The next method can be used for authentication only when the current method does not work.

The Enable authentication function automatically takes effect after configuring the Enable authentication method list.

**Configuration Examples** The following example defines an AAA Enable authentication method list. In the authentication method list, first the RADIUS security server is used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

```
Ruijie(config)# aaa authentication enable default group radius local
```

## 1.9 aaa authentication login

Use this command to enable AAA Login authentication and configure the Login authentication method list.

Use the **no** form of this command to delete the authentication method list.

```
aaa authentication login { default | list-name } method1 [ method2.. ]
```

```
no aaa authentication login { default | list-name }
```

| Parameter          | Parameter      | Description                                                       |
|--------------------|----------------|-------------------------------------------------------------------|
| <b>Description</b> | <b>default</b> | When this parameter is used, the following defined authentication |

|                  |                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|                  | method list is used as the default method for Login authentication.                                                                         |
| <b>list-name</b> | Name of the user authentication method list, which could be any character strings                                                           |
| <b>method</b>    | It must be one of the keywords: <b>local</b> , <b>none</b> , <b>group</b> and <b>subs</b> . One method list can contain up to four methods. |
| <b>local</b>     | Uses the local user name database for authentication.                                                                                       |
| <b>none</b>      | Does not perform authentication.                                                                                                            |
| <b>group</b>     | Uses the server group for authentication. At present, the RADIUS and TACACS+ server groups are supported.                                   |
| <b>subs</b>      | Uses the subs database for authentication.                                                                                                  |

**Defaults** N/A

**Command** Global configuration mode

**Mode**

**Usage Guide** If the AAA Login authentication security service is enabled on the device, users must use AAA for Login authentication negotiation. You must use the **aaa authentication login** command to configure a default or optional method list for Login authentication.

The next method can be used for authentication only when the current method does not work.

You need to apply the configured Login authentication method to the terminal line which needs Login authentication. Otherwise, the configured Login authentication method is invalid.

**Configuration Examples** The following example defines an AAA Login authentication method list named list-1. In the authentication method list, first the RADIUS security server is used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

```
Ruijie(config)# aaa authentication login list-1 group radius local
```

|                       | <b>default</b>   | When this parameter is used, the following defined authentication method list is used as the default method for SSL VPN user authentication. |
|                       | <i>list-name</i> | Name of SSL VPN user authentication method list, which could be any character strings                                                        |
|                       | <i>method</i>    | It must be one of the keywords: <b>local</b> , <b>none</b> , <b>subs</b> and <b>group</b> . One method list can contain up to four methods.  |
|                       | <b>local</b>     | Use the local user name database for authentication.                                                                                         |
|                       | <b>none</b>      | Does not perform authentication.                                                                                                             |
|                       | <b>group</b>     | Uses the server group for authentication. At present, the RADIUS server group is supported.                                                  |
|                       | <b>subs</b>      | Uses the subs database for authentication.                                                                                                   |

**Defaults** N/A

**Command** Global configuration mode

**Mode**

**Usage Guide** If the SSL VPN security service is enabled on the device, users must use the AAA authentication for SSL VPN negotiation. You must use the **aaa authentication sslvpn** command to configure a default or optional method list for user authentication.

The next method can be used for authentication only when the current method does not work.

**Configuration Examples** The following example defines an AAA authentication method list named **rds\_sslvpn** for SSL VPN session. In the authentication method list, the RADIUS security server is first used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

```
Ruijie(config)# aaa authentication sslvpn rds_sslvpn group radius local
```

**Description**

## 1.12 aaa authentication web-auth

Use this command to enable AAA second-generation Web authentication and configure the second-generation Web authentication method list in global configuration mode.

Use the **no** form of this command to delete the authentication method list.

**aaa authentication web-auth** { **default** | *list-name* } *method1* [ *method2...* ]

**no aaa authentication web-auth** { **default** | *list-name* }

**Parameter Description**

| Parameter        | Description                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>default</b>   | When this parameter is used, the following defined authentication method list is used as the default method for the second-generation Web authentication. |
| <i>list-name</i> | Name of second-generation Web authentication method list, which could be any character strings                                                            |
| <i>method</i>    | It must be one of the keywords: <b>local</b> , <b>none</b> , <b>subs</b> and <b>group</b> . One method list can contain up to four methods.               |
| <b>local</b>     | Uses the local user name database for authentication.                                                                                                     |
| <b>none</b>      | Does not perform authentication.                                                                                                                          |

|              |                                                                                             |
|--------------|---------------------------------------------------------------------------------------------|
| <b>group</b> | Uses the server group for authentication. At present, the RADIUS server group is supported. |
| <b>subs</b>  | Uses the subs database for authentication.                                                  |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** If the AAA second-generation Web security service is enabled on the device, users must use AAA for the second-generation Web authentication negotiation. You must use the **aaa authentication web-auth** command to configure a default or optional method list for user authentication. The next method can be used for authentication only when the current method does not work.

**Configuration Examples** The following example defines an AAA authentication method list named **rds\_web**. In the authentication method list, the RADIUS security server is first used for authentication. If the RADIUS security server does not respond, the local user database is used for authentication.

```
Ruijie(config)# aaa authentication web-auth rds_web group radius none
```

## 1.13 aaa authorization commands

Use this command to authorize the command executed by the user who has logged in the NAS CLI. Use the **no** form of this command to restore the default setting.

**aaa authorization commands** *level* { **default** | *list-name* } *method1* [ *method2...* ]

**no aaa authorization commands** *level* { **default** | *list-name* }

| Parameter Description | Parameter        | Description                                                                                                             |
|-----------------------|------------------|-------------------------------------------------------------------------------------------------------------------------|
|                       | <i>level</i>     | Command level to be authorized in the range from 0 to 15                                                                |
|                       | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for command authorization. |
|                       | <i>list-name</i> | Name of the user authorization method list, which could be any character strings                                        |
|                       | <i>method</i>    | It must be one of the keywords: <b>none</b> and <b>group</b> . One method list can contain up to four methods.          |
|                       | <b>none</b>      | Do not perform authorization.                                                                                           |
|                       | <b>group</b>     | Uses the server group for authorization. At present, the TACACS+ server group is supported.                             |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS supports authorization of the commands executed by the users. When the users input and attempt to execute a command, AAA sends this command to the security server. This command is to be executed if the security server allows to. Otherwise, it will prompt command deny.

It is necessary to specify the command level when configuring the command authorization, and this specified command level is the default command level.

The configured command authorization method must be applied to terminal line which requires the command authorization. Otherwise, the configured command authorization method is ineffective.

**Configuration** The following example uses the TACACS+ server to authorize the level 15 command.

**Examples**

```
Ruijie(config)# aaa authorization commands 15 default group tacacs+
```

| Related Commands | Command                       | Description                                              |
|------------------|-------------------------------|----------------------------------------------------------|
|                  | <b>aaa new-model</b>          | Enables the AAA security service.                        |
|                  | <b>authorization commands</b> | Applies the command authorization for the terminal line. |

**Platform** N/A

**Description**

## 1.14 aaa authorization config-commands

Use this command to authorize the configuration commands (including in the global configuration mode and its sub-mode).

Use the **no** form of this command to restore the default setting.

**aaa authorization config-commands**

**no aaa authorization config-commands**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** If you only authorize the commands in the non-configuration mode (for example, privileged EXEC mode), you can use the **no** form of this command to disable the authorization function in the configuration mode, and execute the commands in the configuration mode and its sub-mode without command authorization.

**Configuration** The following example enables the configuration command authorization function.

**Examples**

```
Ruijie(config)# aaa authorization config-commands
```

| Related Commands | Command                           | Description                            |
|------------------|-----------------------------------|----------------------------------------|
|                  | <b>aaa new-model</b>              | Enables the AAA security service.      |
|                  | <b>aaa authorization commands</b> | Defines the AAA command authorization. |

**Platform** N/A

**Description**

## 1.15 aaa authorization console

Use this command to authorize the commands of the users who have logged in the console.

Use the **no** form of this command to restore the default setting.

**aaa authorization console**

**no aaa authorization console**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** RGOS supports to identify the users logged in from the console and from other terminals, configure whether to authorize the users logged in from the console or not. If the command authorization function is disabled on the console, the authorization method list applied to the console line is ineffective.

**Configuration** The following example enables the aaa authorization console function.

**Examples**

```
Ruijie(config)# aaa authorization console
```

| Related Commands | Command                           | Description                                             |
|------------------|-----------------------------------|---------------------------------------------------------|
|                  | <b>aaa new-model</b>              | Enables the AAA security service.                       |
|                  | <b>aaa authorization commands</b> | Defines the AAA command authorization.                  |
|                  | <b>authorization commands</b>     | Applies the command authorization to the terminal line. |

**Platform** N/A

**Description**

## 1.16 aaa authorization exec

Use this command to authorize the users logged in the NAS CLI and assign the authority level.

Use the **no** form of this command to restore the default setting.

**aaa authorization exec** { **default** | *list-name* } *method1* [ *method2...* ]

**no aaa authorization exec** { **default** | *list-name* }

| Parameter   | Parameter        | Description                                                                                                          |
|-------------|------------------|----------------------------------------------------------------------------------------------------------------------|
| Description | <b>default</b>   | When this parameter is used, the following defined method list is used as the default method for Exec authorization. |
|             | <i>list-name</i> | Name of the user authorization method list, which could be any character strings                                     |
|             | <i>method</i>    | It must be one of the keywords listed in the following table. One method list can contain up to four methods.        |
|             | <b>local</b>     | Uses the local user name database for authorization.                                                                 |
|             | <b>none</b>      | Does not perform authorization.                                                                                      |
|             | <b>group</b>     | Uses the server group for authorization. At present, the RADIUS server group is supported.                           |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** RGOS supports authorization of users logged in the NAS CLI and assignment of CLI authority level (0-15). The **aaa authorization exec** function is effective on condition that Login authentication function has been enabled. It cannot enter the CLI if it fails to enable the **aaa authorization exec**. You must apply the exec authorization method to the terminal line; otherwise the configured method is ineffective.

**Configuration** The following example uses the RADIUS server to authorize Exec.

**Examples**

```
Ruijie(config)# aaa authorization exec default group radius
```

| Related  | Command                   | Description                                             |
|----------|---------------------------|---------------------------------------------------------|
| Commands | <b>aaa new-model</b>      | Enables the AAA security service.                       |
|          | <b>authorization exec</b> | Applies the command authorization to the terminal line. |
|          | <b>username</b>           | Defines a local user database.                          |

**Platform** N/A

**Description**

## 1.17 aaa authorization network

Use this command to authorize the service requests (including such protocols as PPP and SLIP) from the users that access the network.

Use the **no** form of this command to restore the default setting.

**aaa authorization network** { **default** | *list-name* } *method1* [ *method2...*]

**no aaa authorization network** { **default** | *list-name* }

| Parameter   | Parameter      | Description                                                                                                             |
|-------------|----------------|-------------------------------------------------------------------------------------------------------------------------|
| Description | <b>default</b> | When this parameter is used, the following defined method list is used as the default method for Network authorization. |
|             | <i>method</i>  | It must be one of the keywords: none and group. One method list can contain up to four methods.                         |
|             | <b>none</b>    | Does not perform authorization.                                                                                         |
|             | <b>group</b>   | Uses the server group for authorization. At present, the RADIUS server group is supported.                              |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** RGOS supports authorization of all the service requests related to the network, such as PPP and SLIP. If authorization is configured, all the authenticated users or interfaces will be authorized automatically.

Three different authorization methods can be specified. Like authorization, the next method can be used for authorization only when the current authorization method does not work. If the current authorization method fails, other subsequent authorization method is not used.

The RADIUS server authorizes authenticated users by returning a series of attributes. Therefore, RADIUS authorization is based on RADIUS authorization. RADIUS authorization is performed only when the user passes the RADIUS authorization.

**Configuration** The following example uses the RADIUS server to authorize network services.

**Examples**

```
Ruijie(config)# aaa authorization network default group radius
```

| Related  | Command                   | Description                       |

|          | <b>aaa authentication</b> | Defines AAA authentication.       |
|          | <b>username</b>           | Defines a local user database.    |

**Platform** N/A

**Description**

## 1.18 aaa domain

Use this command to configure the domain attributes.

Use the **no** form of this command to restore the default setting.

**aaa domain** { **default** | *domain-name* }

**no aaa domain** { **default** | *domain-name* }

| Parameter   | Parameter          | Description                                          |
|-------------|--------------------|------------------------------------------------------|
| Description | <b>default</b>     | Uses this parameter to configure the default domain. |
|             | <i>domain-name</i> | The name of the specified domain                     |

**Defaults** No domain is configured by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to configure the domain-name-based AAA service. The **default** is to configure the default domain. That is the method list used by the network device if the users are without domain information. The *domain-name* is the specified domain name, if the users are with this *domain name*, the method lists associated with this domain are used. At present, the system can configure up to 32 domains.

**Configuration** The following example configures the domain name.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)#
```

**Description**

## 1.23 aaa log rate-limit

Use this command to set the rate of printing the syslog informing AAA authentication success.

Use the **no** form of this command to restore the default printing rate.

**aaa log rate-limit** *num*

**no aaa log rate-limit**

| Parameter          | Parameter  | Description                                                                                                                      |
|--------------------|------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <i>num</i> | The number of syslog entries printed per second. The range is from 0 to 65,535.<br>0 indicates the printing rate is not limited. |

**Defaults** The default is 5.

**Command** Global configuration mode

**Mode**

**Usage Guide** Too much printing may flood the screen or even reduce device performance. In this case, use this command to adjust the printing rate.

**Configuration** The following example sets the rate of printing the syslog informing AAA authentication success to 10.

**Examples**

```
Ruijie(config)# aaa log rate-limit 10
```

**Description**

## 1.24 aaa new-model

Use this command to enable the RGOS AAA security service.

Use the **no** form of this command to restore the default setting.

**aaa new-model**

**no aaa new-model**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to enable AAA. If AAA is not enabled, none of the AAA commands can be configured.

**Configuration Examples** The following example enables the AAA security service.

```
Ruijie(config)# aaa new-model
```

| Related Commands | Command                   | Description                                |
|------------------|---------------------------|--------------------------------------------|
|                  | <b>aaa authentication</b> | Defines a user authentication method list. |
|                  | <b>aaa authorization</b>  | Defines a user authorization method list.  |
|                  | <b>aaa accounting</b>     | Defines a user accounting method list.     |

**Platform Description** N/A

## 1.25 access-limit

Use this command to configure the number of users limit for the domain, which is only valid for the IEEE802.1 users.

Use the **no** form of this command to restore the default setting.

**access-limit num**

**no access-limit**

| Parameter   | Parameter  | Description                                                                    |
|-------------|------------|--------------------------------------------------------------------------------|
| Description | <i>num</i> | The number used for the user limitation is only valid for the IEEE802.1 users. |

**Defaults** By default, no number of users is limited.

**Command** Domain configuration mode

**Mode**

**Usage Guide** This command limits the number of users for the domain.

**Configuration** The following example sets the number of users to 20 for the domain named ruijie.com.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# access-limit 2
```

**Related****Commands**

| Command                  | Description                       |
|--------------------------|-----------------------------------|
| <b>aaa new-model</b>     | Enables the AAA security service. |
| <b>aaa domain enable</b> | Switchover the user level.        |
| <b>show aaa domain</b>   | Defines a local user database.    |

**Platform** N/A

**Description**

## 1.26 accounting network

Use this command to configure the Network accounting list.

Use the **no** form of this command to restore the default setting.

**accounting network { default | list-name }**

**no accounting network**

**Parameter****Description**

| Parameter        | Description                                             |
|------------------|---------------------------------------------------------|
| <b>default</b>   | Uses this parameter to specify the default method list. |
| <i>list-name</i> | The name of the network accounting list                 |

**Defaults**

With no method list specified, if the user sends the request, the device will attempt to specify the default method list for the user.

**Command**

Domain configuration mode

**Mode**

**Usage Guide** Use this command to configure the Network accounting method list for the specified domain.

**Configuration** The following example sets the Network accounting method list for the specified domain.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# accounting network default
```

**Related****Commands**

| Command                  | Description                                |

**Description**

## 1.27 authentication dot1x

Use this command to configure the IEEE802.1x authentication list.

Use the **no** form of this command to restore the default setting.

**authentication dot1x** { **default** | *list-name* }

**no authentication dot1x**

| Parameter          | Parameter        | Description                                            |
|--------------------|------------------|--------------------------------------------------------|
| <b>Description</b> | <b>default</b>   | Uses this parameter to specify the default method list |
|                    | <i>list-name</i> | The name of the specified method list                  |

**Defaults** With no method list specified, if users send the request, the device will attempt to specify the default method list for users.

**Command** Domain configuration mode

**Mode**

**Usage Guide** Specify an IEEE802.1x authentication method list for the domain.

**Configuration** The following example sets an IEEE802.1x authentication method list for the specified domain.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# authentication dot1x default
```

**Description**

## 1.28 authorization network

Use this command to configure the Network authorization list.

Use the **no** form of this command to restore the default setting.

**authorization network** { **default** | *list-name* }

**no authorization network**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |                  |                                                         |
|--------------------|------------------|---------------------------------------------------------|
| <b>Description</b> | <b>default</b>   | Uses this parameter to specify the default method list. |
|                    | <i>list-name</i> | The name of the specified method list                   |

**Defaults** With no method list specified, if users send the request, the device will attempt to specify the default method list for users.

**Command Mode** Domain configuration mode

**Usage Guide** Specify an authorization method list for the domain.

**Configuration** The following example sets an authorization method list for the specified domain.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# authorization network default
```

|                  | <b>show aaa domain</b>   | Displays the domain configuration.         |

**Platform Description** N/A

## 1.29 clear aaa local user lockout

Use this command to clear the lockout user list.

**clear aaa local user lockout { all | user-name word }**

| Parameter Description | Parameter             | Description                          |
|-----------------------|-----------------------|--------------------------------------|
|                       | <b>all</b>            | Indicates all locked users.          |
|                       | <b>user-name word</b> | Indicates the ID of the locked User. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear all the user lists or a specified user list.

**Configuration** The following example clears the lockout user list.

**Examples**

```
Ruijie(config)# clear aaa local user lockout all
```

|                    | <b>default</b>     | Displays the default domain.   |
| <b>Description</b> | <i>domain-name</i> | Displays the specified domain. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** If no domain-name is specified, all domain information will be displayed.

**Configuration** The following example displays the domain named domain.com.

```
Ruijie(config)# show aaa domain domain.com
=====Domain domain.com=====
State: Active
Username format: Without-domain
Access limit: No limit
802.1X Access statistic: 0

Selected method list:
  authentication dot1x default
```

## 1.36 state

Use this command to set whether the configured domain is valid.

Use the **no** form of this command to restore the default setting.

**state { block | active }**  
**no state**

| Parameter   | Parameter     | Description                       |
|-------------|---------------|-----------------------------------|
| Description | <b>block</b>  | The configured domain is invalid. |
|             | <b>active</b> | The configured domain is valid.   |

**Defaults** The default is active.

**Command Mode** Domain configuration mode

**Usage Guide** Use this command to set whether the specified configured domain is valid.

**Configuration** The following example sets the configured domain to be invalid.

**Examples**

```
Ruijie(config)# aaa domain ruijie.com
Ruijie(config-aaa-domain)# state block
```

## 2 RADIUS Commands

### 2.1 aaa group server radius

Use this command to enter AAA server group configuration mode.

Use the **no** form of this command to restore the default setting.

**aaa group server radius** *name*  
**no aaa group server radius** *name*

| Parameter   | Parameter   | Description                                                                                                                     |
|-------------|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>name</i> | Server group name. Keywords “radius” and “tacacs +” are excluded as they are the default RADIUS and TACACS+ server group names. |

**Defaults** N/A

**Command** Global configuration mode  
**Mode**

**Usage Guide** This command is used to configure a RADIUS AAA server group.

**Configuration** The following example configures a RADIUS AAA server group named ss.

```
Ruijie(config)# aaa group server radius ss
Ruijie(config-gs-radius)# end
Ruijie# show aaa group
Type      Reference Name
-----
radius    1          radius
tacacs+   1          tacacs+
radius    1          ss
```

**Description**

## 2.2 ip radius source-interface

Use this command to specify the source IP address for the RADIUS packet.

Use the **no** form of this command to delete the source IP address for the RADIUS packet.

**ip radius source-interface** *interface-name*

**no radius source-interface** *interface-name*

**Parameter  
Description**

| Parameter             | Description                                                           |
|-----------------------|-----------------------------------------------------------------------|
| <i>interface-name</i> | Interface that the source IP address of the RADIUS packet belongs to. |

**Defaults** The source IP address of the RADIUS packet is set by the network layer.

**Command  
mode** Global configuration mode

**Usage Guide** In order to reduce the NAS information to be maintained on the RADIUS server, use this command to set the source IP address of the RADIUS packet. This command uses the first IP address of the specified interface as the source IP address of the RADIUS packet. This command is used in the layer 3 devices.

**Configuration** The following example specifies that the RADIUS packet obtains an IP address from the fastEthernet 0/0 interface and uses it as the source IP address of the RADIUS packet.

**Examples**

```
Ruijie(config)# ip radius source-interface fastEthernet 0/0
```

**Related Commands**

| Command                   | Description                                 |
|---------------------------|---------------------------------------------|
| <b>radius-server host</b> | Defines the RADIUS server.                  |
| <b>ip address</b>         | Configures the IP address of the interface. |

**Platform** N/A

**Description**

## 2.3 ip oob

Use this command to specify the MGMT port used in the TACACS+ server group.

Use the **no** form of this command to restore the default setting.

**ip oob** [ *via mgmt\_name* ]

**no ip oob**

**Parameter Description**

| Parameter        | Description    |
|------------------|----------------|
| <i>mgmt_name</i> | MGMT port name |

**Defaults** N/A

**Command** TACACS+ server group configuration mode

**Mode**

**Usage Guide** Use the **aaa group server tacacs+** command to enter TACACS+ server group configuration mode. If no port is specified as the MGMT port, MGMT Port 0 is default.

## 2.4 ip vrf forwarding

Use this command to select a VRF for the AAA server group.

Use the **no** form of this command to restore the default setting.

**ip vrf forwarding** *vrf\_name*

**no ip vrf forwarding**

| Parameter Description | Parameter       | Description |
|-----------------------|-----------------|-------------|
|                       | <i>vrf_name</i> | VRF name    |

**Defaults** N/A

**Command** Server group configuration mode

**Mode**

**Usage Guide** This command is used to select a VRF for the specified server.

**Configuration** The following example selects the VRF named *vrf\_name* for AAA server group *ss*.

**Examples**

```
Ruijie(config)# aaa group server radius ss
Ruijie(config-gs-radius)# server 192.168.4.12
Ruijie(config-gs-radius)# server 192.168.4.13
Ruijie(config-gs-radius)# ip vrf forwarding vrf_name
Ruijie(config-gs-radius)# end
```

**Description**

## 2.5 radius vendor-specific extend

Use this command to extend RADIUS not to differentiate the IDs of private vendors.

Use the **no** form of this command to restore the default setting.

**radius vendor-specific extend**

**no radius vendor-specific extend**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

- Defaults** Only the private vendor IDs of Ruijie are recognized.
- Command** Global configuration mode
- Mode**
- Usage Guide** This command is used to identify the attributes of all vendor IDs by type.

**Configuration** The following example extends RADIUS so as not to differentiate the IDs of private vendors:

**Examples**

```
Ruijie(config)# radius vendor-specific extend
```

**Related  
Commands**

| Command                   | Description                                                                     |
|---------------------------|---------------------------------------------------------------------------------|
| <b>radius attribute</b>   | Configures vendor type.                                                         |
| <b>radius set qos cos</b> | Sets the QoS value sent by the RADIUS server as the cos value of the interface. |

- Platform** N/A
- Description**

## 2.6 radius vendor-specific attribute support

Use this command to configure whether RADIUS accounting request packets carry the private attribute of a specified vendor.

Use the **no** form of this command to configure that RADIUS accounting request packets do not carry the private attribute of a specified vendor.

**radius vendor-specific attribute support { cisco | huawei | ms}**

**no radius vendor-specific attribute support { cisco | huawei | ms}**

**Parameter  
Description**

| Parameter     | Description                                   |
|---------------|-----------------------------------------------|
| <b>cisco</b>  | Indicates the private attribute of Cisco.     |
| <b>huawei</b> | Indicates the private attribute of Huawei.    |
| <b>ms</b>     | Indicates the private attribute of Microsoft. |

- Defaults** By default, RADIUS accounting request packets carry the private attribute of a specified vendor.
- Command** Global configuration mode
- Mode**
- Usage Guide** This command is used to configure whether RADIUS accounting request packets carry the private attribute of a specified vendor as required.
- Configuration** 1. The following example configures that RADIUS accounting request packets carry the private attribute of Huawei.
- Examples**

```
Ruijie(config)# radius vendor-specific attribute support huawei
```

2. The following example configures that RADIUS accounting request packets do not carry the private attribute of Huawei.

```
Ruijie(config)# no radius vendor-specific attribute support huawei
```

## 2.7 radius-server account update retransmit

Use this command to configure accounting update packet retransmission for the second generation Web authentication user.

Use the **no** form of this command to restore the default setting,

**radius-server account update retransmit**

**no radius-server account update retransmit**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure accounting update packet retransmission for the second generation Web authentication user exclusively.

**Configuration Examples** The following example configures accounting update packet retransmission for the second generation Web authentication user.

```
Ruijie(config)#radius-server account update retransmit
```

#### Related Commands

| Command | Description |

**Platform Description** N/A

## 2.8 radius-server attribute 31

Use this command to specify the MAC-based format of RADIUS Calling-Station-ID attribute.

Use the **no** form of this command to restore the default setting.

**radius-server attribute 31 mac format { ietf | normal | unformatted }**

**no radius-server attribute 31 mac format**

**Parameter Description**

| Parameter          | Description                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <b>ietf</b>        | The standard format specified by the IETF RFC3580. '-' is used as the separator, for example: 00-D0-F8-33-22-AC. |
| <b>normal</b>      | Normal format representing the MAC address. ':' is used as the separator. For example: 00d0.f833.22ac.           |
| <b>unformatted</b> | No format and separator. By default, unformatted is used. For example: 00d0f83322ac.                             |

**Defaults**

The default format is unformatted.

**Command Mode**

Global configuration mode

**Usage Guide**

Some RADIUS security servers (mainly used to 802.1x authentication) may identify the IETF format only. In this case, the RADIUS Calling-Station-ID attribute shall be set as the IETF format type.

**Configuration Examples**

The following example defines the RADIUS Calling-Station-ID attribute as IETF format.

```
Ruijie(config)# radius-server attribute 31 mac format ietf
```

## 2.9 radius-server attribute class

Use this command to analyze the flow control value of the RADIUS CLASS attributes.

Use the **no** form of this command to restore the default setting.

**radius-server attribute class user-flow-control { format-16bytes | format-32bytes }**

**no radius-server attribute class user-flow-control**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                          |                                                     |
|--------------------------|-----------------------------------------------------|
| <b>user-flow-control</b> | Analyzes flow control value in the CLASS attribute. |
| <b>format-16bytes</b>    | Sets the format of flow control value to 16 bytes.  |
| <b>format-32bytes</b>    | Sets the format of flow control value to 32 bytes.  |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is required if the server pushes the flow control value through the CLASS attribute.

**Configuration Examples** The following example analyzes the flow control value of the CLASS attribute and sets the format to 32 bytes.

```
Ruijie(config)#radius-server attribute class user-flow-control
format-32bytes
```

**Platform Description** N/A

## 2.10 radius-server dead-criteria

Use this command to configure criteria on a device to determine that the Radius server is unreachable.

Use the **no** form of this command to restore the default setting.

**radius-server dead-criteria** { **time** *seconds* [ **tries** *number* ] | **tries** *number* }

**no radius-server dead-criteria** { **time** [ **tries** ] | **tries** }

**Parameter Description**

| Parameter                  | Description                                                                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>time</b> <i>seconds</i> | Configures the timeout value. If the device does not receive a correct response packet from the Radius server within the specified time, the Radius server is considered to be unreachable. The value is in the range from 1 to 120 in the unit of seconds.         |
| <b>tries</b> <i>number</i> | Configures the successive timeout times. When sending a request from the device to the Radius server times out for the specified times, the device considers that the Radius server is unreachable. The value is in the range from 1 to 100 in the unit of seconds. |

**Defaults** The default **time** *seconds* is 60 and **tries** *number* is 10.

**Command** Global configuration mode  
**Mode**

**Usage Guide** If a Radius server meets the timeout and timeout times at the same time, it is considered to be unreachable. This command is used to adjust the parameter conditions of timeout and timeout times.

**Configuration** The following example sets the timeout to 120 seconds and timeout times to 20.

**Examples**

```
Ruijie(config)# radius-server dead-criteria time 120 tries 20
```

**Related  
Commands**

| Command                       | Description                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------|
| <b>radius-server host</b>     | Defines the RADIUS security server.                                                            |
| <b>radius-server deadtime</b> | Defines the duration when a device stops sending any requests to an unreachable Radius server. |
| <b>radius-server timeout</b>  | Defines the timeout for the packet re-transmission.                                            |

**Platform** N/A  
**Description**

## 2.11 radius-server deadtime

Use this command to configure the duration when a device stops sending any requests to an unreachable Radius server.

Use the **no** form of this command to restore the default setting.

**radius-server deadtime** *minutes*

**no radius-server deadtime**

**Parameter  
Description**

| Parameter      | Description                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>minutes</i> | Defines the duration in minutes when the device stops sending any requests to the unreachable Radius server. The value is in the range from 1 to 1,440 in the unit of minutes. |

**Defaults** The default value of *minutes* is 0, that is, the device keeps sending requests to the unreachable Radius server.

**Command** Global configuration mode  
**Mode**

**Usage Guide** If active Radius server detection is enabled on the device, the time parameter of this command does not take effect on the Radius server. Otherwise, the Radius server becomes reachable when the duration set by this command is shorter than the unreachable time.

**Configuration** The following example sets the duration when the device stops sending requests to 1 minute.

**Examples** Ruijie(config)# radius-server deadtime 1

| <b>radius-server dead-criteria</b> | Defines the criteria to determine that a Radius server is unreachable. |

**Platform** N/A

**Description**

## 2.12 radius-server host

Use this command to specify a RADIUS security server host.

Use the **no** form of this command to restore the default setting.

**radius-server host** [ **oob** [ **via** *mgmt-name* ] ] { *ipv4-address* | *ipv6-address* } [ **auth-port** *port-number* ] [ **acct-port** *port-number* ] [ **test username** *name* [ **idle-time** *time* ] ] [ **ignore-auth-port** ] [ **ignore-acct-port** ] [ **key** [ **0** | **7** ] *text-string* ]  
**no radius-server host** { *ipv4-address* | *ipv6-address* }

**Parameter  
Description**

| Parameter                           | Description                                                                                                                                                                               |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>oob</b> [ <i>via mgmt-name</i> ] | Specifies an MGMT port as the source port for TACACS+ communication. The default is MGMT Port 0.                                                                                          |
| <i>ipv4-address</i>                 | IPv6 address of the RADIUS security server host.                                                                                                                                          |
| <i>ipv6-address</i>                 | IPv4 address of the RADIUS security server host.                                                                                                                                          |
| <b>auth-port</b>                    | UDP port used for RADIUS authentication.                                                                                                                                                  |
| <i>port-number</i>                  | Number of the UDP port used for RADIUS authentication. If it is set to 0, this host does not perform authentication.                                                                      |
| <b>acct-port</b>                    | UDP port used for RADIUS accounting.                                                                                                                                                      |
| <i>port-number</i>                  | Number of the UDP port used for RADIUS accounting. If it is set to 0, this host does not perform accounting.                                                                              |
| <b>test username</b> <i>name</i>    | (Optional) Enables the active detection to the RADIUS security server and specify the username used by the active detection.                                                              |
| <b>idle-time</b> <i>time</i>        | (Optional) Sets the interval of sending the test packets to the reachable RADIUS security server, which is 60 minutes by default and in the range of 1 to 1440 minutes (namely 24 hours). |
| <b>ignore-auth-port</b>             | (Optional) Disables the detection to the authentication port on the RADIUS security server. It is enabled by default.                                                                     |
| <b>ignore-acct-port</b>             | (Optional) Disables the detection to the authentication port on the RADIUS security server. It is enabled by default.                                                                     |

|                                         |                                                                                                                                                  |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>key</b> [ 0   7 ] <i>text-string</i> | Configure a shared key for the server. The type of encryption can be specified. 0 is no encryption and 7 is simple encryption. The default is 0. |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|

**Defaults** No RADIUS host is specified by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** In order to implement the AAA security service using RADIUS, you must define a RADIUS security server. You can define one or more RADIUS security servers using the **radius-server host** command.

**Configuration** The following example defines a RADIUS security server host:

**Examples**

```
Ruijie(config)# radius-server host 192.168.12.1
```

The following example defines a RADIUS security server host in the IPv4 environment, enable the active detection with the detection interval 60 minutes and disable the accounting UDP port detection:

```
Ruijie(config)# radius-server host 192.168.100.1 test username viven idle-time
60 ignore-acct-port
```

The following example defines a RADIUS security server host in the IPv6 environment

```
Ruijie(config)# radius-server host 3000::100
```

**Related  
Commands**

| Command                         | Description                                               |
|---------------------------------|-----------------------------------------------------------|
| <b>aaa authentication</b>       | Defines the AAA authentication method list                |
| <b>radius-server key</b>        | Defines a shared password for the RADIUS security server. |
| <b>radius-server retransmit</b> | Defines the number of RADIUS packet retransmissions.      |

**Platform** N/A

**Description**

## 2.13 radius-server key

Use this command to define a shared password for the network access server (device) to communicate with the RADIUS security server.

Use the **no** form of this command to restore the default setting.

**radius-server key** [ 0 | 7 ] *text-string*

**no radius-server key**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |                    |                                                                        |
|--------------------|--------------------|------------------------------------------------------------------------|
| <b>Description</b> |                    |                                                                        |
|                    | <i>text-string</i> | Text of the shared password                                            |
|                    | <b>0   7</b>       | Password encryption type.<br>0: no encryption;<br>7: Simply-encrypted. |

**Defaults** No shared password is specified by default.

**Command**

**Mode** Global configuration mode.

**Usage Guide** A shared password is the basis for communications between the device and the RADIUS security server. In order to allow the device to communicate with the RADIUS security server, you must define the same shared password on the device and the RADIUS security server.

**Configuration** The following example defines the shared password **aaa** for the RADIUS security server:

**Examples** Ruijie(config)# radius-server key aaa

|                         |                                 |                                                      |
|-------------------------|---------------------------------|------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>                  | <b>Description</b>                                   |
|                         | <b>radius-server host</b>       | Defines the RADIUS security server.                  |
|                         | <b>radius-server retransmit</b> | Defines the number of RADIUS packet retransmissions. |
|                         | <b>radius-server timeout</b>    | Defines the timeout for the RADIUS packet.           |

**Platform** N/A

**Description**

## 2.14 radius-server retransmit

Use this command to configure the number of packet retransmissions before the device considers that the RADIUS security server does not respond.

Use the **no** form of this command to restore the default setting.

**radius-server retransmit** *retries*

**no radius-server retransmit**

|                              |                  |                                                                                                   |
|------------------------------|------------------|---------------------------------------------------------------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b> | <b>Description</b>                                                                                |
|                              | <i>retries</i>   | Number of retransmissions in the range from 0 to 100. The value of 0 indicates no retransmission. |

**Defaults** The default is 3.

**Command** Global configuration mode.  
**Mode**

**Usage Guide** AAA uses the next method to authenticate users only when the current security server for authentication does not respond. When the device retransmits the RADIUS packet for the specified times and the interval between every two retries is timeout, the device considers that the security sever does not respond.

**Configuration** The following example sets the number of retransmissions to 4.

**Examples**

```
Ruijie(config)# radius-server retransmit 4
```

| Related<br>Commands | Command                      | Description                                      |
|---------------------|------------------------------|--------------------------------------------------|
|                     | <b>radius-server host</b>    | Defines the RADIUS security server.              |
|                     | <b>radius-server key</b>     | Defines a shared password for the RADIUS server. |
|                     | <b>radius-server timeout</b> | Defines the timeout for the RADIUS packet.       |

**Platform** N/A  
**Description**

## 2.15 radius-server source-port

Use this command to configure the source port to send RADIUS packets.

Use the **no** form of this command to restore the default setting.

**radius-server source-port** *port*

**no radius-server source-port**

| Parameter<br>Description | Parameter   | Description                                |
|--------------------------|-------------|--------------------------------------------|
|                          | <i>port</i> | The port ID, in the range from 0 to 65535. |

**Defaults** The default is a random number.

**Command** Global configuration mode  
**Mode**

**Usage Guide** The source port is random by default. This command is used to specify a source port.

**Configuration** The following example configures source port 10000 to send RADIUS packets.

**Examples**

```
Ruijie(config)# radius-server source-port 10000
```

**Description**

## 2.16 radius-server timeout

Use this command to set the time for the device to wait for a response from the security server after retransmitting the RADIUS packet.

Use the **no** form of this command to restore the default setting.

**radius-server timeout** *seconds*

**no radius-server timeout**

| Parameter<br>Description | Parameter      | Description |
|--------------------------|----------------|-------------|
|                          | <i>seconds</i> |             |

**Defaults** The default is 5 seconds.

**Command**

**Mode** Global configuration mode

**Usage Guide** This command is used to change the timeout of packet retransmission.

**Configuration** The following example sets the timeout to 10 seconds.

**Examples**

```
Ruijie(config)# radius-server timeout 10
```

| Related<br>Commands             | Command                   | Description                                              |

**Description**

## 2.17 radius-server authentication attribute

Use this command to enable access-request packets to contain a specified RADIUS attribute.

Use the **no** or **default** form of this command to restore the default setting.

**radius-server authentication attribute** *type package*

**no radius-server authentication attribute *type* package**  
**default radius-server authentication attribute *type* package**

Use this command to disable access-request packets to contain a specified RADIUS attribute.  
 Use the **no** or **default** form of this command to restore the default setting.

**radius-server authentication attribute *type* unpackage**  
**no radius-server authentication attribute *type* unpackage**  
**default radius-server authentication attribute *type* unpackage**

| <b>Parameter Description</b>  | Parameter                                                                                  | Description                                 |
|-------------------------------|--------------------------------------------------------------------------------------------|---------------------------------------------|
|                               | <i>type</i>                                                                                | RADIUS attribute in the range from 1 to 255 |
| <b>Defaults</b>               | RFC-compliant                                                                              |                                             |
| <b>Command Mode</b>           | Global configuration mode                                                                  |                                             |
| <b>Usage Guide</b>            | Use this command to enable access-request packets to contain a specified RADIUS attribute. |                                             |
| <b>Configuration Examples</b> | The following example disables access-request packets to contain attribute NAS-PORT-ID.    |                                             |
|                               | <pre>Ruijie(config)# radius-server authentication attribute 87 unpackage</pre>             |                                             |
| <b>Platform Description</b>   | N/A                                                                                        |                                             |

## 2.18 radius-server account attribute

Use this command to enable account-request packets to contain a specified RADIUS attribute.  
 Use the **no** or **default** form of this command to restore the default setting.

**radius-server account attribute *type* package**  
**no radius-server account attribute *type* package**  
**default radius-server account attribute *type* package**

Use this command to disable account-request packets to contain a specified RADIUS attribute.  
 Use the **no** or **default** form of this command to restore the default setting.

**radius-server account attribute *type* unpackage**  
**no radius-server account attribute *type* unpackage**  
**default radius-server account attribute *type* unpackage**

| <b>Parameter Description</b> | Parameter   | Description                                 |
|------------------------------|-------------|---------------------------------------------|
|                              | <i>type</i> | RADIUS attribute in the range from 1 to 255 |

|                               |                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | RFC-compliant                                                                                          |
| <b>Command Mode</b>           | Global configuration mode                                                                              |
| <b>Usage Guide</b>            | Use this command to enable or disable account-request packets to contain a specified RADIUS attribute. |
| <b>Configuration Examples</b> | The following example disables account-request packets to contain attribute NAS-PORT-ID.               |
| <b>Examples</b>               | <pre>Ruijie(config)# radius-server account attribute 87 unpackage</pre>                                |
| <b>Platform Description</b>   | N/A                                                                                                    |

## 2.19 radius-server authentication vendor

Use this command to enable access-request packets to contain vendor-specific RADIUS attributes.

Use the **no** or **default** form of this command to restore the default setting.

**radius-server authentication vendor [cmcc | microsoft | cisco] package**

**no radius-server authentication vendor *vendor\_name* package**

**default radius-server authentication vendor *vendor\_name* package**

| Parameter Description | Parameter                       | Description |
|-----------------------|---------------------------------|-------------|
|                       | <b>cmcc   microsoft   cisco</b> | Vendor name |

|                               |                                                                                                  |
|-------------------------------|--------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | Access-request packets do not contain vendor- specific RADIUS attributes by default.             |
| <b>Command Mode</b>           | Global configuration mode                                                                        |
| <b>Usage Guide</b>            | Use this command to enable access-request packets to contain vendor- specific RADIUS attributes. |
| <b>Configuration Examples</b> | The following example enables access-request packets to contain "cmcc".                          |
| <b>Examples</b>               | <pre>Ruijie(config)# radius-server authentication vendor cmcc package</pre>                      |
| <b>Platform Description</b>   | N/A                                                                                              |

## 2.20 radius-server account vendor

Use this command to enable account-request packets to contain vendor-specific RADIUS attributes.

Use the **no** or **default** form of this command to restore the default setting.

```
radius-server account vendor [cmcc | microsoft | cisco ] package
no radius-server account vendor vendor_name package
default radius-server account vendor vendor_name package
```

| Parameter<br>Description | Parameter | Description              |
|--------------------------|-----------|--------------------------|
|                          |           | cmcc   microsoft   cisco |

**Defaults** Account-request packets do not contain vendor- specific RADIUS attributes by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to enable account-request packets to contain vendor-specific RADIUS attributes.

**Configuration Examples** The following example enables account-request packets to contain "cmcc".

```
Ruijie(config)# radius-server account vendor cmcc package
```

**Platform Description** N/A

## 2.21 radius set qos cos

Use this command to set the QoS value sent by the RADIUS server as the CoS value of the interface. Use the **no** form of this command to restore the default setting.

```
radius set qos cos
no radius set qos cos
```

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** Set the QoS value sent by the RADIUS server as the DSCP value.

**Command Mode** Global configuration mode.

**Usage Guide** This command is used to set the QoS value sent by the RADIUS server as the CoS value, and the DSCP value by default.

**Configuration Examples** The following example sets the QoS value sent by the RADIUS server as the CoS value of the interface:

```
Ruijie(config)# radius set qos cos
```

| Related Commands | Command | Description                          |
|------------------|---------|--------------------------------------|
|                  |         | <b>radius vendor-specific extend</b> |

**Platform** N/A

**Description**

## 2.22 radius support cui

Use this command to enable RADIUS to support the cui function.

Use the **no** form of this command to restore the default setting.

**radius support cui**

**no radius support cui**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to enable RADIUS to support the cui function.

**Configuration Examples** The following example enables RADIUS to support the cui function.

```
Ruijie(config)# radius support cui
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  |         | N/A         |

**Platform** N/A

**Description**

## 2.23 server auth-port acct-port

Use this command to add the server of the AAA server group.

Use the **no** form of this command to restore the default setting.

**server** { *ipv4-addr* | *ipv6-addr* } [ **auth-port** *port1* ] [ **acct-port** *port2* ]

**no server** { *ipv4-addr* | *ipv6-addr* } [ **auth-port** *port1* ] [ **acct-port** *port2* ]

| Parameter Description | Parameter        | Description                |
|-----------------------|------------------|----------------------------|
|                       | <i>ip-addr</i>   | Server IP address          |
|                       | <i>ipv6-addr</i> | Server IPv6 address        |
|                       | <i>port1</i>     | Server authentication port |
|                       | <i>port2</i>     | Server accounting port     |

**Defaults** No server is configured by default.

**Command Mode** Server group configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example adds server 192.168.4.12 to server group ss and sets the accounting port and authentication port to 5 and 6 respectively.

```
Ruijie(config)# aaa group server radius ss
Ruijie(config-gs-radius)# server 192.168.4.12 acct-port 5 auth-port 6
Ruijie(config-gs-radius)# end
Ruijie# show aaa group
Type      Reference Name
-----
radius    1          radius
tacacs+   1          tacacs+
radius    1          ss
```

| Related Commands | Command | Description |

## 2.24 show radius acct statistics

Use this command to display RADIUS accounting statistics.

**show radius acct statistics**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode/Privileged EXEC mode/Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example displays RADIUS accounting statistics.

```
Ruijie#show radius acct statistics
Accounting Servers:

Server Index..... 1
Server Address..... 192.168.1.1
Server Port..... 1813
Msg Round Trip Time..... 0 (msec)
First Requests..... 1
Retry Requests..... 1
Accounting Responses..... 0
Malformed Msgs..... 0

## 3 TACACS+ Commands

### 3.1 aaa group server tacacs+

Use this command to configure different groups of TACACS+ server hosts.

Use the **no** form of this command to remove a specified TACACS server group.

**aaa group server tacacs+ group\_name**

**no aaa group server tacacs+ group\_name**

| Parameter   | Parameter         | Description                                                                                                             |
|-------------|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| Description | <i>group_name</i> | TACACS+ server group name, which cannot be <b>radius</b> or <b>tacacs+</b> . The two names are the built-in group name. |

**Defaults** No TACACS+ server group is configured.

**Command** Global configuration mode

**Mode**

**Usage Guide** After you group different TACACS+ servers, the tasks of authentication, authorization and accounting can be implemented by different server groups.

**Configuration Examples** The following example configures a TACACS+ server group named tac1, and configures a TACACS+ server with IP address 1.1.1.1 in this group:

```
Ruijie(config)#aaa group server tacacs+ tac1
Ruijie(config-gs-tacacs)# server 1.1.1.1
```

| Related Commands | Command                  | Description                                            |
|------------------|--------------------------|--------------------------------------------------------|
|                  | <b>server</b>            | Configures server list of TACACS+ server group.        |
|                  | <b>ip vrf forwarding</b> | Configures VRF name supported by TACACS+ server group. |

**Platform** N/A

**Description**

### 3.2 ip tacacs source-interface

Use this command to use the IP address of a specified interface for all outgoing TACACS+ packets.

Use the **no** form of this command to disable use of the specified interface IP address.

**ip tacacs source-interface** *interface-name*

**no ip tacacs source-interface** *interface-name*

| Parameter   | Parameter             | Description                                |
|-------------|-----------------------|--------------------------------------------|
| Description | <i>interface-name</i> | Interface for the outgoing TACACS+ packets |

**Defaults** The source IP address of TACACS+ packets is set on the network layer.

**Command Mode** Global configuration mode

**Usage Guide** To decrease the work of maintaining massive NAS messages in TACACS+ server, use this command to use the IP address of a specified interface for all outgoing TACACS+ packets. This command specifies the primary IP address of the specified interface as the source address of TACACS+ packets on Layer 3 devices. If the specified interface is in a VRF instance, the route of this VRF instance is used for packet transmission.

**Configuration Examples** The following example specifies the IP address of GigabitEthernet 0/0 for the outgoing TACACS+ packets.

```
Ruijie(config)# ip tacacs source-interface gigabitEthernet 0/0
```

| Related Commands | Command                   | Description                                |
|------------------|---------------------------|--------------------------------------------|
|                  | <b>tacacs-server host</b> | Defines a TACACS+ server.                  |
|                  | <b>ip address</b>         | Configures the IP address of an interface. |

**Platform Description** N/A

### 3.3 ip oob

Use this command to specify the MGMT port used in the TACACS+ server group.

Use the **no** form of this command to restore the default setting.

**ip oob** [ *via mgmt\_name* ]

**no ip oob**

| Parameter   | Parameter        | Description    |
|-------------|------------------|----------------|
| Description | <i>mgmt_name</i> | MGMT port name |

**Defaults** N/A

|                      |                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Command</b>       | TACACS+ server group configuration mode                                                                                                 |
| <b>Mode</b>          |                                                                                                                                         |
| <b>Usage Guide</b>   | Use the <b>aaa group server tacacs+</b> command to enter TACACS+ server group configuration mode. No MGMT port is specified by default. |
| <b>Configuration</b> | N/A                                                                                                                                     |
| <b>Examples</b>      |                                                                                                                                         |
| <b>Platform</b>      | N/A                                                                                                                                     |
| <b>Description</b>   |                                                                                                                                         |

### 3.4 ip vrf forwarding

Use this command to configure the VRF used in the TACACS+ server group.

Use the **no** form of this command to remove the VRF configuration from the TACACS+ server group.

**ip vrf forwarding** *vrf-name*

**no ip vrf forwarding**

| <b>Parameter</b><br><b>Description</b> | Parameter       | Description |
|----------------------------------------|-----------------|-------------|
|                                        | <i>vrf-name</i> | VRF name    |

**Defaults** N/A

**Command** TACACS+ server group configuration mode  
**Mode**

**Usage Guide** Before you configure this command, you need to use the **aaa group server tacacs+** command to enter TACACS+ server group configuration mode. The VRF instance must exist and be configured with a correct VRF name through the **vrf definition** command.

**Configuration** The following example specifies the VRF instance named vpn1 for the TACACS+ server group:

**Examples**

```
Ruijie(config)# aaa group server tacacs+ tac1
Ruijie(config-gs-tacacs)# server 1.1.1.1
Ruijie(config-gs-tacacs)# ip vrf forwarding vpn1
```

| <b>Related</b><br><b>Commands</b> | Command                         | Description                                       |
|-----------------------------------|---------------------------------|---------------------------------------------------|
|                                   | <b>aaa group server tacacs+</b> | Configures the TACACS+ server group.              |
|                                   | <b>server</b>                   | Configures a server list of TACACS+ server group. |

**Platform** N/A  
**Description**

### 3.5 server

Use this command to configure the IP address of the TACACS+ server for the group server.  
 Use the **no** form of this command to remove the TACACS+ server.

**server** { *ipv4-address* | *ipv6-address* }

**no server** { *ipv4-address* | *ipv6-address* }

| Parameter Description | Parameter           | Description                        |
|-----------------------|---------------------|------------------------------------|
|                       | <i>ipv4-address</i> | IPv4 address of the TACACS+ server |
|                       | <i>ipv6-address</i> | IPv6 address of the TACACS+ server |

**Defaults** No TACACS+ server is configured by default.

**Command Mode** TACACS+ server group configuration mode

**Usage Guide** You must configure the **aaa group server tacacs+** command before configuring this command.  
 To configure server address in TACACS+ group server, you must use the **tacacs-server host** command in global configuration mode.  
 If there is no response from the first host entry, the next host entry is tried.

**Configuration Examples** The following example configures a TACACS+ server group named tac1 and a TACACS+ server address 1.1.1.1 in this group.

```
Ruijie(config)#aaa group server tacacs+ tac1
Ruijie(config-gs-tacacs)# server 1.1.1.1
```

| Related Commands | Command                         | Description                        |
|------------------|---------------------------------|------------------------------------|
|                  | <b>aaa group server tacacs+</b> | Configures a TACACS+ server group. |

**Platform** N/A  
**Description**

### 3.6 show tacacs

Use this command to display the TACACS+ server configuration.

**show tacacs**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Command Mode** Privileged EXEC mode/Global configuration/Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the TACACS+ server configuration.

```
Ruijie# show tacacs
Tacacs+ Server : 172.19.192.80/49
Socket Opens: 0
Socket Closes: 0
Total Packets Sent: 0
Total Packets Recv: 0
Reference Count: 0
```

| Related<br>Commands | Command | Description               |
|---------------------|---------|---------------------------|
|                     |         | <b>tacacs-server host</b> |

**Platform Description** N/A

### 3.7 tacacs-server host

Use this command to configure a TACACS+ host.

Use the **no** form of this command to remove the TACACS+ host.

**tacacs-server host** [ **oob** [ **via** *mgmt-name* ] ] { *ip-v4-address* | *ip-v6-address* } [ **port** *integer* ] [ **timeout** *integer* ] [ **key** [ **0** | **7** ] *text-string* ]

**no tacacs-server host** { *ip-address* | *ip-v6-address* }

| Parameter<br>Description | Parameter                                  | Description                                                                  |
|--------------------------|--------------------------------------------|------------------------------------------------------------------------------|
|                          |                                            | <i>ip-address</i>                                                            |
|                          | <i>ip-v6-address</i>                       | IPv6 address of the TACACS+ host                                             |
|                          | <b>oob</b> [ <b>via</b> <i>mgmt-name</i> ] | Specifies an MGMT port as the source port for TACACS+ communication.         |
|                          | <b>port</b> <i>integer</i>                 | Port number of the server. The range is from 1 to 65,535. The default is 49. |

|                               |                                                                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>timeout</b> <i>integer</i> | Timeout time of TACACS+ host. The range is from 1 to 1,000.                                                                                                    |
| <b>key</b> <i>string</i>      | Configures an authentication and encryption key. The value can be 0 or 7.<br>0 indicates no encryption, while 7 indicates simple encryption. The default is 0. |

**Defaults** No TACACS+ host is specified by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** The TACACS+ host must be configured to implement AAA security service. You can use this command to configure one or multiple TACACS+ hosts.

**Configuration** The following example configures a TACACS+ host.

**Examples** Ruijie(config)# tacacs-server host 192.168.12.1

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Description**

### 3.8 tacacs-server key

Use this command to configure the authentication encryption key used for TACACS+ communications between the access server and the TACACS+ server.

Use the **no** form of this command to remove the authentication encryption key.

**tacacs-server key** [ 0 | 7 ] *string*

**no tacacs-server key**

**Parameter  
Description**

| Parameter     | Description                                                                        |
|---------------|------------------------------------------------------------------------------------|
| <i>string</i> | Key string                                                                         |
| 0   7         | Encryption type of key<br>0 indicates no encryption; 7 indicate simple encryption. |

**Defaults** No authentication encryption key is configured by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** Use command to configure a global authentication and encryption key for TACACS+ communication. Use the **key** parameter in the **tacacs-server host** command to configure a server-based key.

**Configuration** The following example defines the authentication encryption key of TACACS+ server as aaa:

**Examples**

```
Ruijie(config)# tacacs-server key aaa
```

**Related Commands**

| Command                   | Description             |
|---------------------------|-------------------------|
| <b>tacacs-server host</b> | Defines a TACACS+ host. |

**Platform Description** N/A

### 3.9 tacacs-server timeout

Use this command to set the interval for which the server waits for a server host to reply. Use the **no** form of this command to restore the default timeout interval.

**tacacs-server timeout seconds**

**no tacacs-server timeout**

**Parameter Description**

| Parameter      | Description                                                          |
|----------------|----------------------------------------------------------------------|
| <i>seconds</i> | Timeout interval in the range from 1 to 1,000 in the unit of seconds |

**Defaults** The default is 5 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Use command to configure a global timeout interval. Use the **timeout** parameter in the **tacacs-server host** command to configure a server-based interval.

**Configuration** The following example configures the timeout interval to 10 seconds.

**Examples**

```
Ruijie(config)# tacacs-server timeout 10
```

**Related Commands**

**Platform Description** N/A

## 4 802.1X Commands

### 4.1 aaa authorization ip-auth-mode

Use this command to set the IP authorization mode.

**aaa authorization ip-auth-mode { disable | supplicant | radius-server | dhcp-server | mixed }**

| Parameter   | Parameter            | Description                               |
|-------------|----------------------|-------------------------------------------|
| Description | <b>disable</b>       | Disables IP authorization mode.           |
|             | <b>supplicant</b>    | Enables supplicant authorization mode.    |
|             | <b>radius-server</b> | Enables Radius server authorization mode. |
|             | <b>dhcp-server</b>   | Enables DHCP server authorization mode.   |
|             | <b>mixed</b>         | Enables mixed authorization mode.         |

**Defaults** IP authorization mode is disabled by default.

**Command mode** Global configuration mode

**Usage Guide** Supplicant authorization mode supports only Ruijie supplicant.  
 Radius-server authorization mode requires the server to allocate IP addresses by framed-ip.  
 DHCP-server authorization mode requires the server to enable DHCP snooping or DHCP relay.  
 Mixed authorization mode supports multiple authorization methods.

**Configuration** The following example enables supplicant authentication mode.

**Examples**

```
Ruijie(config)# aaa authorization ip-auth-mode supplicant
```

### 4.2 clear dot1x user all

Use this command to clear all the 802.1X authentication users.

**clear dot1x user all**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear all the 802.1X authentication users.

**Configuration** The following example clears all the 802.1X authentication users.

**Examples** Ruijie#clear dot1x user all

| Related Commands | Command | Description |

|                  | N/A     | N/A         |

**Platform Description** N/A

### 4.3 clear dot1x user mac

Use this command to clear 802.1X authentication users according to MAC addresses.

**clear dot1x user mac** *mac-addr*

| Parameter Description | Parameter       | Description |
|-----------------------|-----------------|-------------|
|                       | <i>mac-addr</i> | MAC address |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear 802.1X authentication users according to MAC addresses.

**Configuration** The following example clears an 802.1X authentication user whose MAC address is 0012.3456.789A.

**Examples** Ruijie#clear dot1x user mac 0012.3456.789A

### 4.4 clear dot1x user name

Use this command to clear the 802.1 X authentication users according to the username.

**clear dot1x user name** *name-str*

| Parameter   | Parameter       | Description                                    |
|-------------|-----------------|------------------------------------------------|
| Description | <i>name-str</i> | The username of the 802.1X authentication user |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear the 802.1 X authentication users according to the username.

**Configuration** The following example clears the 802.1X authentication user named 802.1X-user.

**Examples** Ruijie#clear dot1x user name dot1x-user

| Related  | Command | Description |

**Platform** N/A

**Description**

## 4.5 clear dot1x user ip

Use this command to clear 802.1X authentication users according to IP addresses.

**clear dot1x user ip** *ip-addr*

| Parameter   | Parameter      | Description |
|-------------|----------------|-------------|
| Description | <i>ip-addr</i> | IP address  |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear 802.1X authentication users according to IP addresses.

**Configuration** The following example clears an 802.1X authentication user whose IP address is 11.1.1.1.

**Examples** Ruijie#clear dot1x user ip 11.1.1.1

**Platform** N/A

**Description**

## 4.6 dot1x accounting

Use this command to configure the accounting list.

**dot1x accounting** *list-name*

| Parameter   | Parameter        | Description                     |
|-------------|------------------|---------------------------------|
| Description | <i>list-name</i> | The name of the accounting list |

**Defaults** N/A

**Command Mode** Global configuration mode/WLAN security configuration mode

**Usage Guide** If AAA does not adopt 802.1X accounting as the default accounting method. Use this command to configure the 802.1X accounting method.  
Configuration in WLAN security configuration mode is prior to that in global configuration mode.

**Configuration Examples** The following example configures the accounting list.

```
Ruijie(config)# dot1x accounting dot1x-acct
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 4.7 dot1x acct-update base-on first-time server

Use this command to assign the accounting update interval for the first authentication.

Use the **no** form of this command to restore the default settings.

**dot1x acct-update base-on first-time server**

**no dot1x acct-update base-on first-time server**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** The assignment is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Some portal servers do not support the assignment of accounting update interval during re-authentication.

Use this command if such servers demand users to issue accounting update packets according to the interval in the first authentication.

**Configuration** The following example assigns the accounting update interval for the first authentication.

**Examples**

```
Ruijie(config)# dot1x acct-update base-on first-time server
```

**Platform** N/A  
**Description**

## 4.8 dot1x auth-fail max-attempt

Use this command to set the maximum auth-attempts.

Use the **no** form of this command to restore the default setting.

**dot1x auth-fail max-attempt** *value*

**no dot1x auth-fail max-attempt**

| Parameter          | Parameter    | Description               |
|--------------------|--------------|---------------------------|
| <b>Description</b> | <i>value</i> | The maximum auth-attempts |

**Defaults** The default is 3.

**Command Mode** Global configuration mode

**Usage Guide** Use the **show dot1x** command to adjust the maximum authentication attempts for those failed users.

**Configuration** The following example sets the maximum auth-attempts to 2.

**Examples**

```
Ruijie(config)# dot1x auth-fail max-attempt 2
```

| Related Commands | Command           | Description                        |
|------------------|-------------------|------------------------------------|
|                  | <b>show dot1x</b> | Displays the 802.1x configuration. |

**Description**

## 4.9 dot1x auth-mode

Use this command to specify the 802.1X authentication mode.

**dot1x auth-mode** { **eap** | **chap** | **pap** }

| Parameter          | Parameter   | Description                          |
|--------------------|-------------|--------------------------------------|
| <b>Description</b> | <b>eap</b>  | Enables EAP-MD5 authentication mode. |
|                    | <b>chap</b> | Enables CHAP authentication mode.    |

|            |                                  |
|------------|----------------------------------|
| <b>pap</b> | Enables PAP authentication mode. |
|------------|----------------------------------|

**Defaults** The default is EAP-MD5 authentication mode.

**Command Mode** Global configuration mode

**Usage Guide** The selection of authentication mode depends on the suppliant and portal server.

**Configuration** The following example enables CHAP authentication mode.

**Examples** Ruijie(config)# dot1x auth-mode chap

| Related Commands | Command           | Description                      |
|------------------|-------------------|----------------------------------|
|                  | <b>show dot1x</b> | Displays the 802.1X information. |

**Platform Description** N/A

## 4.10 dot1x auth-address-table address

Use this command to configure the authentication address table.

**dot1x auth-address-table address** *mac-addr* **interface** *interface*

| Parameter Description | Parameter        | Description                                |
|-----------------------|------------------|--------------------------------------------|
|                       | <i>mac-addr</i>  | The MAC address of the authentication host |
|                       | <i>interface</i> | The interface of the authentication host   |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** Only the specified interface with the specified MAC address is able to pass the 802.1x authentication.

**Configuration** The following example configures the authentication address table.

**Examples** Ruijie(config)# dot1x auth-address-table 00d0.f800.0cb2 interface fastethernet 0/1

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 4.11 dot1x authentication

Use this command to configure the authentication method list.

**dot1x authentication** *list-name*

|           | Parameter        | Description                |
|-----------|------------------|----------------------------|
| Parameter | <i>list-name</i> | Authentication method list |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** If AAA does not adopt the default 802.1X authentication, use this command to configure the 802.1X authentication method.

**Configuration** The following example configures the authentication method list

**Examples** Ruijie(config)# dot1x authentication dot1x-authen

|                  | Command | Description |
|------------------|---------|-------------|
| Related Commands | N/A     | N/A         |

**Platform** N/A

**Description**

## 4.12 dot1x auto-req

Use this command to configure auto-request 802.1X authentication.

Use the **no** form of this command to restore the default setting.

**dot1x auto-req**

**no dot1x auto-req**

|           | Parameter | Description |
|-----------|-----------|-------------|
| Parameter | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Enable this function for MAB. If the authentication agent is already in the terminal system, enable it by clicking.

**Configuration** The following example enables auto-request 802.1X authentication.

**Examples**

```
Ruijie(config)# dot1x auto-req
```

| Related Commands | Command                          | Description                                                |
|------------------|----------------------------------|------------------------------------------------------------|
|                  | <code>show dot1x auto-req</code> | Displays the automatic authentication request information. |

**Platform** N/A

**Description**

## 4.13 dot1x auto-req packet-num

Use this command to set the number of auto-request authentication packets.

**dot1x auto-req packet-num** *num*

| Parameter          | Parameter  | Description                                                                        |
|--------------------|------------|------------------------------------------------------------------------------------|
| <b>Description</b> | <i>num</i> | The number of auto-request authentication packets in the range from 0 to 1,000,000 |

**Defaults** The default is 0.

**Command** N/A

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the number of auto-request authentication packets to 100.

**Examples**

```
Ruijie(config)# dot1x auto-req packet-num 100
```

| Related Commands | Command                          | Description                                      |
|------------------|----------------------------------|--------------------------------------------------|
|                  | <code>show dot1x auto-req</code> | Displays the authentication request information. |

**Platform** N/A

**Description**

## 4.14 dot1x auto-req req-interval

Use this command to set the auto-request authentication interval.

**dot1x auto-req req-interval** *time*

| Parameter          | Parameter   | Description                                                                                    |
|--------------------|-------------|------------------------------------------------------------------------------------------------|
| <b>Description</b> | <i>time</i> | The auto-request authentication interval, in the range from 10 to 3,600 in the unit of seconds |

**Defaults** The default is 30 seconds.

**Command** Global configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the auto-request authentication interval to 50 seconds.

**Examples**

```
Ruijie(config)# dot1x auto-req req-interval 50
```

| Related         | Command                          | Description                                      |
|-----------------|----------------------------------|--------------------------------------------------|
| <b>Commands</b> | <code>show dot1x auto-req</code> | Displays the authentication request information. |

**Platform** N/A  
**Description**

## 4.15 dot1x auto-req user-detect

Use this command to enable online user detection for auto-request authentication.

Use the **no** form of this command to disable this function.

**dot1x auto-req user-detect**

**no dot1x auto-req user-detect**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example enables online user detection for auto-request authentication.

**Examples**

```
Ruijie(config)# dot1x auto-req user-detect
```

| Related         | Command                          | Description                                      |
|-----------------|----------------------------------|--------------------------------------------------|
| <b>Commands</b> | <code>show dot1x auto-req</code> | Displays the authentication request information. |

**Platform** N/A  
**Description**

## 4.16 dot1x client-probe enable

Use this command to enable online user probe function.

Use the **no** form of this command to restore the default setting.

**dot1x client-probe enable**

**no dot1x client-probe enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to enable online user probe function.

**Configuration Examples** The following example enables online user probe function.

```
Ruijie(config)# dot1x client-probe enable
```

| Related Commands | Command           | Description                    |
|------------------|-------------------|--------------------------------|
|                  | <b>show dot1x</b> | Displays 802.1X configuration. |

**Platform Description** N/A

## 4.17 dot1x critical

Use this command to enable the server IAB (Inaccessible Authentication Bypass) on the port.

Use the **no** form of this command to restore the default setting.

**dot1x critical**

**no dot1x critical**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This functions is disabled by default.

**Command Mode** Interface configuration mode/VXLAN mode

**Usage Guide** With the IAB function enabled on the port, if there is only RADIUS authentication method in the 802.1X authentication method list and all RADIUS servers in this method list take no effect, the

switch will set the network accessing authority for users by the IAB method, and send the EAPOL-SUCCESS packets to the users.

Except for the RADIUS authentication method, if there are other authentication methods in the 802.1X authentication method list, the IAB function will take no effect. (Such as the **aaa authentication dot1x default group radius none**, there exists none authentication method after the RADIUS authentication method.

For the users of IAB authorized, as the user identity legality cannot be checked, no matter whether the accounting function is configured, they will not send the accounting request.

With the AAA multi-domain authentication enabled globally, the 802.1X user authentication will not use the globally configured method list. After all RADIUS servers in the 802.1X globally configured method list are checked to be invalid, the IAB will directly send the successful authentication to the user with no need to enter the username, the AAA multi-domain authentication on this port is useless.

**Configuration Examples** The following example enables the server IAB (Inaccessible Authentication Bypass) function on the port.

```
Ruijie(config-if-GigabitEthernet 0/5)#dot1x critical
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 4.18 dot1x critical recovery action reinitialize

Use this command to allow IAB users under the port to reinitialize authentication when the server has recovered.

Use the **no** form of this command to restore the default setting.

**dot1x critical recovery action reinitialize**

**no dot1x critical recovery action reinitialize**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode/VXLAN mode

**Usage Guide** After the port entering the inaccessible authentication bypass status, if the RADIUS server returns to normal, you need to reinitialize the authentication for all users that have accomplished the network access authorization through the inaccessible authentication bypass on ports in order to ensure the user legality.

**Configuration** The following example allows IAB users under the port to reinitialize authentication when the server has recovered.

**Examples**

```
Ruijie(config-if-GigabitEthernet 0/5)#dot1x critical recovery action
reinitialize
```

| Related  | Command | Description |

| Commands | N/A     | N/A         |

**Platform** N/A

**Description**

## 4.19 dot1x critical vlan

Use this command to configure the port in IAB status to jump to a specified auth-fail VLAN.

Use the **no** form of this command to disable this function.

**dot1x critical vlan**

**no dot1x critical vlan**

| Parameter   | Parameter      | Description                       |
|-------------|----------------|-----------------------------------|
| Description | <i>vlan-id</i> | The VLAN where the port will jump |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode/VXLAN mode

**Mode**

**Usage Guide** With this function enabled, if no user authentication is performed on the ports initially, after all RADIUS servers are invalidated, the user will initiate the authentication and the port will enter the IAB status and to be added to the VLAN configured. If this function is disabled, the VLAN of the port is not changed when the port is in the IAB status.

**Configuration** The following example configures the port in IAB status to jump to a specified auth-fail VLAN.

**Examples**

```
Ruijie(config-if-GigabitEthernet 0/5)#dot1x critical vlan 10
```

## 4.20 dot1x dbg-filter

Use this command to enable debug information print for a user with a specified MAC address.

Use the **no** form of this command to clear the debug information.

**dot1x dbg-filter** *H.H.H*

**no dot1x dbg-filter** *H.H.H*

| Parameter   | Parameter    | Description               |
|-------------|--------------|---------------------------|
| Description | <i>H.H.H</i> | The MAC address of a user |

**Defaults** Debug information of all authentication users is printed by default.

**Command mode** Global configuration mode

**Usage Guide** Use this command to print the debug information of a specific user. If you want to locate the fault on the network where there are multiple users.

**Configuration Examples** The following example prints the debug information of the device with the specified MAC address.

```
Ruijie(config)# dot1x dbg-filter 00d0.f800.0001
```

## 4.21 dot1x default-user-limit

Use this command to set the maximum auth-user number on controlled interfaces.

Use the **no** form of this command to restore the default setting.

**dot1x default-user-limit** *num*

**no dot1x default-user-limit**

| Parameter   | Parameter  | Description                                                                                      |
|-------------|------------|--------------------------------------------------------------------------------------------------|
| Description | <i>num</i> | The maximum auth-user number allowed by a controlled interface, in the range from 1 to 1,000,000 |

**Defaults** The default is 1,000,000.

**Command mode** Interface configuration mode/ VXLAN mode

**Usage Guide** This command is used to limit the number of users to be authenticated on a specific port.

**Configuration** The following example sets the maximum auth-user number on a controlled interface.

**Examples**

```
Ruijie(config-if)# dot1x default-user-limit 10
```

| Related Commands | Command                                                    | Description                                                          |

## 4.22 dot1x default

Use this command to restore 802.1X configuration to the default setting.

**dot1x default**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to restore 802.1X configuration for quick re-configuration.

**Configuration** The following example restores 802.1X configuration to the default setting.

**Examples**

```
Ruijie(config)# dot1x default
```

| Related Commands | Command           | Description                      |
|------------------|-------------------|----------------------------------|
|                  | <b>show dot1x</b> | Displays the 802.1X information. |

**Platform** N/A

**Description**

## 4.23 dot1x get-static-ip enable

Use this command to obtain static IP addresses.

**dot1x get-static-ip enable**

Use this command to restore the default setting.

**no dot1x get-static-ip enable****Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

This function is disabled by default.

**Command  
Mode**

Global configuration mode

**Usage Guide**

Enable this function when wireless terminals use static IP addresses and need to upload the static IP addresses to the server.

Note that the IP addresses are uploaded to the server via accounting packets. In addition, when static IP addresses are used, terminal identification information is not provided.

**Configuration**

The following example obtains static IP addresses.

**Examples**

```
Ruijie(config)# dot1x get-static-ip enable
```

**Platform****Description**

This command is supported only on wireless products.

## 4.24 dot1x mab-username upper

Use this command to enable uppercase letters in MAB user names.

**dot1x mab-username upper****Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

This function is disabled by default.

**Command  
Mode**

Global configuration mode.

**Usage Guide**

By default, lowercase letters are used in the user name of MAB. After this function is enabled, uppercase letters are used in new user names of MAB to meet server requirements.

**Configuration**

The following example enables uppercase letters in MAB user names.

**Examples**

```
Ruijie(config)# dot1x mab-username upper
```

Use this command to set the MAB authentication timeout interval.

**dot1x mac-auth-bypass timeout-activity** *time*

**no dot1x mac-auth-bypass timeout-activity**

| Parameter   | Parameter   | Description                                                           |
|-------------|-------------|-----------------------------------------------------------------------|
| Description | <i>time</i> | The online time, in the range from 1 to 65,535 in the unit of seconds |

**Defaults** The default is 0 second.

**Command** Interface configuration mode/VXLAN mode  
**Mode**

**Usage Guide** Use this command to set the MAB authentication timeout interval for dumb terminals.

**Configuration** The following example sets the MAB authentication timeout interval.

**Examples**

```
Ruijie(config-if-GigabitEthernet 0/0)# dot1x mac-auth-bypass  
timeout-activity 3600
```

## 4.28 dot1x mac-auth-bypass violation

Use this command to configure the MAB violation.

Use the **no** form of this command to restore the default setting.

**dot1x mac-auth-bypass violation**

**no dot1x mac-auth-bypass violation**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command is used to configure the MAB violation on the port with only one dumb terminal in single MAB environment.

**Configuration Examples** The following example configures the MAB violation.

```
Ruijie(config-if-GigabitEthernet 0/0)# dot1x mac-auth-bypass violation
```

## 4.29 dot1x mac-auth-bypass vlan

Use this command to configure the MAB VLAN function.

Use the **no** form of this command to restore the default setting.

**dot1x mac-auth-bypass vlan *vlan-list***

**no dot1x mac-auth-bypass vlan *vlan-list***

| Parameter   | Parameter        | Description               |
|-------------|------------------|---------------------------|
| Description | <i>vlan-list</i> | Configures the MAB VLANs. |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Mode**

**Usage Guide** Use this command to allow users within specified VLANs on the port to perform MAB authentication.

**Configuration** The following example configures MAB VLANs.

**Examples**

```
Ruijie(config-if-GigabitEthernet 0/0)# dot1x mac-auth-bypass vlan 5, 8-20
```

## 4.30 dot1x max-req

Use this command to set the maximum attempts of authentication requests.

**dot1x max-req** *num*

| Parameter          | Parameter  | Description      |
|--------------------|------------|------------------|
| <b>Description</b> | <i>num</i> | Maximum attempts |

**Defaults** The default is 3.

**Command** Global configuration mode

**Mode**

**Usage Guide** Use the **show dot1x** command to display the 802.1X configuration.

**Configuration** The following example sets the maximum attempts of authentication requests to 2.

**Examples**

```
Ruijie(config)# dot1x max-req 2
```

**Description**

## 4.31 dot1x multi-account enable

Use this command to enable the user with one single MAC address to perform authentication with multiple accounts.

Use the **no** form of this command to restore the default setting.

**dot1x multi-account enable**

**no dot1x multi-account enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Use the command to enable the multiple-account authentication if you want to switch the username in the authentication or re-authentication, especially in the windows domain authentication.

**Configuration Examples** The following example enables the multiple-account authentication.

```
Ruijie(config)# dot1x multi-account enable
```

## 4.32 dot1x multi-mab quiet-period

Use this command to set the quiet time after the multiple MAB authentication failure.

**dot1x multi-mab quiet-period** *time*

| Parameter   | Parameter   | Description                                                                                                                |
|-------------|-------------|----------------------------------------------------------------------------------------------------------------------------|
| Description | <i>time</i> | Sets the quiet period after the multiple MAB authentication failure, in the range from 0 to 65,535 in the unit of seconds. |

**Defaults** The default is 0 second, indicating no quiet period.

**Command Mode** Global configuration mode

**Usage Guide** The default setting is recommended.

**Configuration Examples** The following example sets the quiet period after the multiple MAB authentication failure to 2 seconds.

```
Ruijie(config)# dot1x multi-mab quiet-period 2
```

## 4.33 dot1x mab-username format

Use this command to configure the MAB authentication user name format.

Use the **no** form of this command to restore the default setting.

**dot1x mab-username format [with-dot | with-colon | with-hyphen]**

**no dot1x mab-username format**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** By default, this function is disabled.

**Command Mode** Global configuration mode

**Usage Guide** **dot1x mab-username format with-dot** is used to configure the MAB authentication user name format xxxx.xxxx.xxxx.

**dot1x mab-username format with-colon** is used to configure the MAB authentication user name format xx:xx:xx:xx:xx:xx.

**dot1x mab-username format with-hyphen** is used to configure the MAB authentication user name format xx-xx-xx-xx-xx-xx.

**Configuration Examples** The following example configures the MAB authentication user name format.

```
Ruijie(config)# dot1x mab-username format with-hyphen
```

**Platform Description** N/A

## 4.34 dot1x port-control auto

Use this command to configure the 802.1X authentication on the port.

Use the **no** form of this command to restore the default setting.

**dot1x port-control auto**

**no dot1x port-control**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode/VXLAN mode

**Mode**

**Usage Guide** Use the **show dot1x** command to display the 802.1X configuration.

**Configuration** The following example configures the 802.1X authentication on the port.

**Examples**

```
Ruijie(config-if-GigabitEthernet 0/0)# dot1x port-control auto
```

| Related Commands | Command           | Description                      |
|------------------|-------------------|----------------------------------|
|                  | <b>show dot1x</b> | Displays the 802.1X information. |

**Platform** N/A

**Description**

## 4.35 dot1x port-control-mode

By default, 802.1x adopts MAC address-based control mode. In this mode, only authenticated users have access to the network, while other users that connect to the same port cannot access the network. In the port-based control mode, however, if one user that connects to the port passes the authentication, this port becomes an authenticated port and all the users that connect to this port have access to the network. In the port-based single-user control mode, the port is authenticated when it allows only one authenticated user who is enable to use the network normally. If you find other users on the port, you should clear all the users on the port and re-authenticate. The authentication mode can be configured using the following commands

**dot1x port-control-mode { mac-based | port-based | port-based single-host}**

**no dot1x port-control-mode**

| Parameter Description | Parameter                     | Description                           |
|-----------------------|-------------------------------|---------------------------------------|
|                       | <b>mac-based</b>              | Enable the MAC address-based control. |
|                       | <b>port-based</b>             | Enable port-based control.            |
|                       | <b>port-based single-host</b> | Enable single host-based control.     |

**Defaults** MAC address-based access control is used by default.

**Command** Interface configuration mode.

**Mode**

**Usage Guide** Use the **show dot1x port-control** command to show the 802.1X configuration for the port. Single-host is port-based single-user 802.1x access control. Use **show dot1x port-control** to display port-based and use **show running-config** to display dot1x port-control-mode port-based single-host. Since single-host only supports the single-user form, setting default-user-limit on the port manually does not take effect in single-host mode. If you set default-user-limit on the port after setting single-host, only one user can be permitted to use the network still.

**Configuration** The following example sets the port to participate in authentication and enable port-based authentication.

**Examples**

```
Ruijie(config-if-GigabitEthernet 0/0)# dot1x port-control-mode port-based
```

| <b>Platform</b>                           | N/A                                                                                                                                                                                                                                          |                    |             |                                           |                                                        |  |

**Description**

## 4.39 dot1x pseudo source-mac

Use this command to use a virtual MAC address as the source MAC address of the 802.1X packets sent by the device.

Use the **no** form of this command to restore the default setting.

**dot1x pseudo source-mac**

**no dot1x pseudo source-mac**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** Global configuration mode

**Usage Guide** By default, the device uses its own MAC address as the source MAC address of the EAP packets for the 802.1X authentication. Some versions of the Ruijie supplicant judge whether the access device is a Ruijie device based on the source MAC address of the EAP packets. If the access device is a Ruijie device, the supplicant device performs some private features. Configure this command if you want to enable these features.

**Configuration Examples** The following example uses the virtual MAC address as the source MAC address of the 802.1X packets sent by the device:

```
Ruijie(config)# dot1x pseudo source-mac
```

**Platform Description** N/A

## 4.40 dot1x redirect

Use this command to enable the second generation SU upgrade function.

Use the **no** form of this command to restore the default setting.

**dot1x redirect**

**no dot1x redirect**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Redirect to the supplicant software download website through the browser. See *Web Authentication Configuration Guide* for details about parameters.

**Configuration Examples** The following example enables the second generation SU upgrade function,

```
Ruijie(config)# dot1x redirect
```

## 4.41 dot1x reauth-max

Use this command to set the maximum re-auth attempts.

```
dot1x reauth-max num
no dot1x reauth-max
```

| Parameter Description | Parameter    | Description                                          |
|-----------------------|--------------|------------------------------------------------------|
|                       | <i>num</i> , | Maximum re-auth attempts. The range is from 1 to 10. |

**Defaults** The default is 3.

**Command Mode** Global configuration mode

**Usage Guide** Use this command to specify the maximum number of supplicant re-authentications. Use the **show dot1x** command to display 802.1X configuration.

**Configuration Examples** The following example sets the maximum re-auth attempts to 2.

```
Ruijie(config)# dot1x reauth-max 2
```

| Related Commands | Command           | Description                      |
|------------------|-------------------|----------------------------------|
|                  | <b>show dot1x</b> | Displays the 802.1X information. |

**Platform Description** N/A

## 4.42 dot1x re-authentication

Use this command to enable timed re-authentication function.

Use the **no** form of the command to restore the default setting.

**dot1x re-authentication**

**no dot1x re-authentication**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command will re-authenticate the supplicant periodically after he passes the authentication. Use the **show dot1x** command to display 802.1X configuration. The default setting is recommended.

**Configuration Examples** The following example enables timed re-authentication function.

```
Ruijie(config)# dot1x re-authentication
```

| Related Commands | Command           | Description                      |
|------------------|-------------------|----------------------------------|
|                  | <b>show dot1x</b> | Displays the 802.1X information. |

**Platform Description** N/A

## 4.43 dot1x stationarity enable

In the port-based 802.1X control mode, dynamic users can transit freely among the ports by default.

Use this command to prevent users from transition.

Use the **no** form of this command to restore the default setting.

**dot1x stationarity enable**

**no dot1x stationarity enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command must be configured before user authentication. Otherwise, you need re-authenticate all the users.

**Configuration** The following example prevents the user from transiting from 802.1X port to other port.

**Examples**

```
Ruijie(config)# dot1x stationarity enable
```

**Description**

## 4.44 dot1x timeout re-authperiod

Use this command to set the re-authentication interval when re-authentication is enabled.

**dot1x timeout re-authperiod** *time*

| Parameter          | Parameter   | Description                                                                    |
|--------------------|-------------|--------------------------------------------------------------------------------|
| <b>Description</b> | <i>time</i> | Authentication interval, in the range from 1 to 65,535 in the unit of seconds. |

**Defaults** The default is 3,600 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Use the **show dot1x** command to display the 802.1X configuration.

**Configuration** The following example sets the re-authentication interval to 2,400 seconds.

**Examples**

```
Ruijie(config)# dot1x timeout re-authperiod 2400
```

| Related Commands | Command           | Description                            |
|------------------|-------------------|----------------------------------------|
|                  | <b>show dot1x</b> | Displays the information about 802.1X. |

**Platform** N/A

**Description**

## 4.45 dot1x timeout quiet-period

Use this command to set the quiet period when authentication fails.

**dot1x timeout quiet-period** *time*

| Parameter   | Parameter   | Description                                                         |
|-------------|-------------|---------------------------------------------------------------------|
| Description | <i>time</i> | Quiet period, in the range from 1 to 65,535 in the unit of seconds. |

**Defaults** The default is 10 seconds.

**Command Mode** Global configuration mode

**Usage Guide** The default value is recommended.

**Configuration Examples** The following example sets the quiet period after failed authentication.

```
Ruijie(config)# dot1x timeout quiet-period 60
```

| Related Commands | Command | Description |

## 4.46 dot1x timeout supp-timeout

Use this command to set the authentication timeout between the device and the supplicant.

**dot1x timeout supp-timeout *time***

| Parameter   | Parameter   | Description                                                                                            |
|-------------|-------------|--------------------------------------------------------------------------------------------------------|
| Description | <i>time</i> | Authentication timeout between the device and the supplicant<br>The range is from 1 to 65,535 seconds. |

**Defaults** The default is 3 seconds.

**Command Mode** Global configuration mode

**Usage Guide** Use the **show dot1x** command to show display 802.1X configuration.

**Configuration Examples** The following example sets the authentication timeout between the device and the supplicant to 10s:

```
Ruijie(config)# dot1x timeout supp-timeout 10
```

| Related Commands | Command           | Description                            |
|------------------|-------------------|----------------------------------------|
|                  | <b>show dot1x</b> | Displays the information about 802.1x. |

**Description**

## 4.47 dot1x timeout server-timeout

Use this command to set the server timeout interval.

**dot1x timeout server-timeout** *time*

| Parameter Description | Parameter   | Description                                                                       |
|-----------------------|-------------|-----------------------------------------------------------------------------------|
|                       | <i>time</i> | The server timeout interval, in the range from 1 to 65,535 in the unit of seconds |

**Defaults** The default is 5 seconds.

**Command Mode** Global configuration mode

**Usage Guide** By default, the timeout of the 802.1X server is less than that of the Radius server. Use this command to raise the 802.1X timeout so as to exceed the Radius value. For details, see *Configuration Guide*.

**Configuration Examples** The following example set the server timeout interval to 10 seconds.

```
Ruijie(config)# dot1x timeout server-timeout 10
```

| Related Commands | Command           | Description                      |

|                  | <b>show dot1x</b> | Displays the 802.1X information. |

**Platform** N/A  
**Description**

## 4.48 dot1x timeout tx-period

Use this command to set the request/id packet re-transmission interval.

**dot1x timeout tx-period** *time*

| Parameter Description | Parameter   | Description                                                                                      |
|-----------------------|-------------|--------------------------------------------------------------------------------------------------|
|                       | <i>time</i> | The request/id packet re-transmission interval, in range from 1 to 65,535 in the unit of seconds |

**Defaults** The default is 3 seconds for switches, and 4 seconds for wireless devices.

**Command** Global configuration mode  
**Mode**

**Usage Guide** Use the **show dot1x** command to display 802.1X configuration.

**Configuration** The following example sets the request/id packet re-transmission interval to 5 seconds.

**Examples**

```
Ruijie(config)# dot1x timeout tx-period 5
```

**Description**

## 4.49 dot1x valid-ip-acct enable

Use this command to enable IP address-triggered accounting.

Use the **no** form of this command to restore the default setting.

**dot1x valid-ip-acct enable**

**no dot1x valid-ip-acct enable**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** Use this command to enable accounting only when users obtain valid IP addresses.

**Configuration** The following example enables IP address-triggered accounting.

**Examples**

```
Ruijie(config)#dot1x valid-ip-acct enable
```

**Platform** N/A

**Description**

## 4.50 dot1x valid-ip-acct timeout

Use this command to configure IP address-triggered accounting timeout.

Use the **no** form of this command to restore the default setting.

**dot1x valid-ip-acct timeout *time***

**no dot1x valid-ip-acct timeout**

|                               |                                                                                                                                                                     |                                                                |

## 4.52 show dot1x

Use this command to display the 802.1X setting.

**show dot1x**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example displays the 802.1X setting.

**Examples**

```
Ruijie#show dot1x

802.1X basic information:
 802.1X Status ..... enable
 Authentication Mode ..... eap
 Authorization mode ..... disable
 Total User Number ..... 0 (exclude dynamic user)
 Authenticated User Number ..... 0 (exclude dynamic user)
 Dynamic User Number ..... 0
 Re-authentication ..... disable
 Re-authentication Period ..... 3600 seconds
 Re-authentication max ..... 3 times
 Quiet Period ..... 10 seconds
 Tx Period ..... 30 seconds
 Supplicant Timeout ..... 3 seconds
 Server Timeout ..... 5 seconds
 Maximum Request ..... 3 times
 Client Online Probe ..... disable
 Eapol Tag ..... enable
 802.1x redirect ..... disable
 Private supplicant only ..... disable
```

|-----------------|-------------------------------------|-------------------------------------------------------------------------------|
| <b>Commands</b> | <b>dot1x auth-mode</b>              | Sets the 802.1X authentication mode.                                          |
|                 | <b>dot1x max-req</b>                | Sets the maximum number of authentication request re-transmissions.           |
|                 | <b>dot1x port-control auto</b>      | Sets the port to participate in authentication.                               |
|                 | <b>dot1x reauth-max</b>             | Sets the maximum number of the supplicant re-authentications.                 |
|                 | <b>dot1x re-authentication</b>      | Sets the re-authentication attribute.                                         |
|                 | <b>dot1x timeout quiet-period</b>   | Sets the time the device waits before re-authentication.                      |
|                 | <b>dot1x timeout re-authperiod</b>  | Sets the re-authentication period for the supplicant.                         |
|                 | <b>dot1x timeout server-timeout</b> | Sets the authentication timeout between the device and authentication server. |
|                 | <b>dot1x timeout supp-timeout</b>   | Sets the authentication timeout between the device and the supplicant.        |
|                 | <b>dot1x timeout tx-period</b>      | Sets the re-transmission interval.                                            |

**Platform** N/A

**Description**

## 4.56 show dot1x port-control

Use this command to display the port-control information.

**show dot1x port-control** [ **interface** *interface-type interface-number*]

| Parameter          | Parameter               | Description    |
|--------------------|-------------------------|----------------|
| <b>Description</b> | <i>interface-type</i>   | Interface type |
|                    | <i>interface-number</i> | Interface ID   |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the port-control information.

### Examples

```
Ruijie#show dot1x port-control
Interface Mode      Dynamic-User Static-User Max-User  Authened MAB
-----
Gi0/5   mac-based  0          0          unlimited no      disable
```

| Related Commands | Command                | Description                                       |
|------------------|------------------------|---------------------------------------------------|
|                  | <b>dot1x auth-mode</b> | Sets the 802.1X authentication mode.              |
|                  | <b>dot1x max-req</b>   | Sets the maximum number of authentication request |

|                                     |                                                                               |
|-------------------------------------|-------------------------------------------------------------------------------|
|                                     | re-transmissions.                                                             |
| <b>dot1x port-control auto</b>      | Sets the port to participate in authentication.                               |
| <b>dot1x reauth-max</b>             | Sets the maximum number of the supplicant re-authentications.                 |
| <b>dot1x re-authentication</b>      | Sets the re-authentication attribute.                                         |
| <b>dot1x timeout quiet-period</b>   | Sets the time the device waits before re-authentication.                      |
| <b>dot1x timeout re-authperiod</b>  | Sets the re-authentication period for the supplicant.                         |
| <b>dot1x timeout server-timeout</b> | Sets the authentication timeout between the device and authentication server. |
| <b>dot1x timeout supp-timeout</b>   | Sets the authentication timeout between the device and the supplicant.        |
| <b>dot1x timeout tx-period</b>      | Sets the re-transmission interval.                                            |

**Description**

## 4.58 show dot1x probe-timer

Use this command to display the configuration of online user probe.

**show dot1x probe-timer**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the configuration of online user probe.

**Examples** Ruijie#show dot1x probe-timer

```
Hello Interval    : 20
Hello Alive       : 60
```

Field Description

| Command        | Description                    |
|----------------|--------------------------------|
| Hello Interval | Sets the probe period.         |
| Hello Alive    | Sets the probe alive interval. |

## 4.59 show dot1x re-authentication

Use this command to display re-authentication status.

**show dot1x re-authentication**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays re-authentication status.

### Examples

```
Ruijie#show dot1x re-authentication
```

```
Reauth-Enabled: Disabled
```

| Command        | Description                          |
|----------------|--------------------------------------|
| Reauth-Enabled | Whether to enable re-authentication. |

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A

**Description**

## 4.60 show dot1x reauth-max

Use this command to display the maximum re-auth attempts.

**show dot1x reauth-max**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the maximum re-authentication attempts.

**Examples**

```
Ruijie#show dot1x reauth-max
Reauth-Max: 3 Times
```

| Command        | Description                                  |
|----------------|----------------------------------------------|
| Reauth-Enabled | Sets the maximum re-authentication attempts. |

## 4.61 show dot1x summary

Use this command to display the 802.1X authentication summary.

**show dot1x summary**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** It is convenient to display the 802.1X authentication summary according to the MAC address or username.

**Configuration** The following example displays the summary of 802.1X authentication.

**Examples**

```
Ruijie#show dot1x summary
ID      User      MAC          Interface VLAN INNER-VLAN Auth-State
Backend-State Port-Status User-Type Time
-----
-----
```

**Description**

## 4.62 show dot1x timeout quiet-period

Use this command to display the time for the device to wait before re-authentication quiet period after the authentication failure.

**show dot1x timeout quiet-period**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** Use this command to display the time for the device to wait before re-authentication quiet period after the authentication failure.

**Configuration Examples** The following example shows how to displays the quiet period the time for the device to wait before re-authentication after the authentication failure.

```
Ruijie#show dot1x timeout quiet-period
```

```
Quiet-Period: 10 Seconds
```

Parameter Description:

| Parameter    | Description                                                                                |
|--------------|--------------------------------------------------------------------------------------------|
| Quiet-Period | The time for the device to wait before re-authentication after the authentication failure. |

## 4.63 show dot1x timeout re-authperiod

Use this command to display the re-authentication interval.

**show dot1x timeout re-authperiod**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** Use this command to display the re-authentication interval.

**Configuration** The following example displays the re-authentication interval.:

**Examples**

```
Ruijie#show dot1x timeout re-authperiod
```

```
Reauth-Period: 3600 Seconds
```

Parameter Description:

| Parameter     | Description                 |
|---------------|-----------------------------|
| Reauth-Period | Re-authentication interval. |

| Related Commands | Command | Description |

## 4.64 show dot1x timeout server-timeout

Use this command to display the authentication timeout period.

**show dot1x timeout server-timeout**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** Use this command to display the authentication timeout period.

**Configuration** Use this command to display the authentication timeout period:

**Examples**

```
Ruijie#show dot1x timeout server-timeout
```

```
Server-Timeout: 5 Seconds
```

Parameter Description:

| Parameter     | Description                                  |
|---------------|----------------------------------------------|
| Server-Period | AuthenticationServer timeout periodinterval. |

## 4.65 show dot1x timeout supp-timeout

Use this command to display the request/challenge packets re-transmission interval.

**show dot1x timeout supp-timeout**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** Use this command to display the request/challenge packets re-transmission interval.

**Configuration** Use this command to display the request/challenge packets re-transmission interval:

**Examples**

```
Ruijie#show dot1x timeout supp-timeout
```

```
Supp-Timeout: 3 Seconds
```

Field Description:

| Field         | Description                                             |
|---------------|---------------------------------------------------------|
| Server-Period | The request/challenge packets re-transmission interval. |

**Description**

## 4.67 show dot1x user mac

Use this command to display the information about 802.1X authentication users based on MAC addresses.

**show dot1x user mac mac-addr**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | mac-addr  | MAC address |

**Defaults** N/A

**Command** Privileged EXEC mode/Global configuration mode/Interface configuration mode  
**Mode**

**Usage Guide** Use the **show dot1x summary** command to display 802.1X authentication summaries. And use this command to display detailed information of a specific user based on its MAC address.

**Configuration Examples** The following example displays the information about the 802.1X authentication user according to the user's MAC address.

```
Ruijie#show dot1x user mac 0023.aeaa.4286
```

```
User name: ts-user
User id: 16777225
Type: static
Mac address is 0023.aeaa.4286
Vlan id is 2
Access from port Gi0/5
Time online: 0days 0h 0m17s
User ip address is 192.168.3.21
Max user number on this port is 0
Authorization session time is 1000 seconds
Supplicant is private
Start accounting
Permit proxy user
Permit dial user
IP privilege is 0
user acl-name ts-user_6_0_0 :
```

Parameter Description:

| Parameter                    | Description                             |
|------------------------------|-----------------------------------------|
| User name                    | User name                               |

## 4.68 show dot1x user name

Use this command to display information about 802.1X authentication users based on usernames.

**show dot1x user name** *name*

| Parameter Description | Parameter   | Description |
|-----------------------|-------------|-------------|
|                       | <i>name</i> | User name   |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** Use the **show dot1x summary** command to display 802.1X authentication summaries. And use this command to display detailed information of a specific user based on its username.

**Configuration Examples** The following example displays the information about the 802.1X authentication user according to the user name.

```
Ruijie#show dot1x user name ts-user

User name: ts-user
User id: 16777225
Type: static
Mac address is 0023.aeaa.4286
Vlan id is 2
Access from port Gi0/5
Time online: 0days 0h 0m17s
User ip address is 192.168.3.21
Max user number on this port is 0
Authorization session time is 1000 seconds
Supplicant is private
Start accounting
Permit proxy user
Permit dial user
IP privilege is 0
user acl-name ts-user_6_0_0 :
```

Parameter Description:

| Parameter                    | Description                              |
|------------------------------|------------------------------------------|
| User name                    | User name                                |
| User id                      | User ID                                  |
| Type                         | User type                                |
| Mac address                  | User's MAC address                       |
| Vlan id                      | User VLAN ID                             |
| Access from port             | The port that user access from           |
| Time online                  | User online time                         |
| User ip address              | User IP address                          |
| Max user number on this port | The maximum number of users on the port  |
| Authorization session time   | The authorized session time              |
| Supplicant is private        | Whether the terminal is a Ruijie device. |
| Start accounting             | The accounting is enabled.               |
| Permit proxy user            | The user is allowed to use the proxy.    |
| Permit dial user             | The user is allowed to dial.             |
| IP privilege                 | The IP privilege level.                  |
| user acl-name                | The ACL information.                     |

## 5 Web Authentication Commands

### 5.1 accounting

Use this command to set an accounting method for the template.

Use the **no** form of this command to restore the default setting.

**accounting** { *method-list* }

**no accounting**

| Parameter Description | Parameter          | Description             |
|-----------------------|--------------------|-------------------------|
|                       | <i>method-list</i> | Name of the method list |

**Defaults** N/A

**Command Mode** Template configuration mode

**Usage Guide** The *method-list* parameter in this command should be consistent with network accounting list name configured in AAA.

**Configuration Examples** The following example sets the **mlist1** accounting method for the **eportalv2** template.

```
Ruijie(config.tmplt.eportalv2)# accounting mlist1
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 5.2 authentication

Use this command to set an authentication method for the template.

Use the **no** form of this command to restore the default setting.

**authentication** { *method-list* }

**no authentication**

| Parameter Description | Parameter          | Description             |
|-----------------------|--------------------|-------------------------|
|                       | <i>method-list</i> | Name of the method list |

**Defaults** N/A

**Command Mode** Template configuration mode

**Usage Guide** The *method-list* parameter in this command should be consistent with the Web authentication method list configured in AAA.  
The first generation authentication does not support the authentication method list configuration.

**Configuration** The following example sets the **mlist1** authentication method for the **eportalv2** template.

**Examples**

```
Ruijie(config.tmplt.eportalv2)#authentication mlist1
```

**Description**

## 5.3 bindmode

Use this command to set a binding mode for the template.

Use the **no** form of this command to restore the default setting.

**bindmode { ip-mac-mode | ip-only-mode }**

**no bindmode**

**Parameter Description**

| Parameter           | Description                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip-mac-mode</b>  | IP+MAC mode. The device will write both the IP address information and the MAC address information into the forwarding entry.                                                                  |
| <b>ip-only-mode</b> | IP only mode. The device writes only the IP address information into the forwarding entry. On the L3 network, it is recommended to adopt this mode in case that the MAC address is inaccurate. |

**Defaults** The default is **ip-mac-mode**.

**Command Mode** Template configuration mode

**Usage Guide** N/A

**Configuration** The following example adopts the IP only mode for the **eportalv2** template.

**Examples**

```
Ruijie(config.tmplt.eportalv2)# bindmode ip-only-mode
```

## 5.7 clear web-auth user

Use this command to force the user to go offline.

**clear web-auth user** { **all** | **ip** { *ip-address* | *ipv6-address* } | **mac** *mac-address* | **name** *name-string* }

| Parameter Description | Parameter           | Description                        |
|-----------------------|---------------------|------------------------------------|
|                       | <i>ip-address</i>   | Specifies the user's IPv4 address. |
|                       | <i>ipv6-address</i> | Specifies the user's IPv6 address. |
|                       | <i>mac-address</i>  | Specifies the user's MAC address.  |
|                       | <i>name-string</i>  | Specifies the user name.           |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example forces all users to go offline.

```
Ruijie(config) clear web-auth user all
```

| Related Commands | Command | Description |

## 5.8 fmt

Use this command to set the URL redirection format in the second template configuration mode.

**fmt** { **cmcc-ext1** | **cmcc-ext2** | **cmcc-normal** }

Use this command to set the URL redirection format in the first template configuration mode.

**fmt** { **ace** | **ruijie** | **custom** }

| Parameter Description | Parameter          | Description          |
|-----------------------|--------------------|----------------------|
|                       | <b>cmcc-ext1</b>   | Extended CMCC format |
|                       | <b>cmcc-ext2</b>   | Liaoning CMCC format |
|                       | <b>cmcc-normal</b> | Standard CMCC format |

|                               |                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | The default URL redirection format is Ruijie format.                                           |
| <b>Command Mode</b>           | Template configuration mode                                                                    |
| <b>Usage Guide</b>            | Use this command to set the URL redirection format based on the corresponding portal standard. |
| <b>Configuration Examples</b> | The following example sets the URL redirection format to extended CMCC format.                 |
| <b>Examples</b>               | <pre>Ruijie(config.tmplt.eportalv2)#fmt cmcc-ext1</pre>                                        |
| <b>Platform Description</b>   | N/A                                                                                            |

## 5.9 http redirect direct-arp

Use this command to set the address range of the authentication-exempted ARP.

Use the **no** form of this command to restore the default setting.

**http redirect direct-arp** { *ip-address* [ *ip-mask* ] }

**no http redirect direct-arp** { *ip-address* [ *ip-mask* ] }

| <b>Parameter Description</b> | Parameter         | Description          |
|------------------------------|-------------------|----------------------|
|                              | <i>ip-address</i> | IPv4 address         |
|                              | <i>ip-mask</i>    | (Optional) IPv4 mask |

| <b>Defaults</b>               | No authentication-exempted ARP resource is configured by default.                                                                                                                                                     |             |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                                                                             |             |
| <b>Usage Guide</b>            | The user cannot learn the ARPs of devices such as the gateway with the ARP CHECK function enabled. Use this command to enable the device to learn the ARP within a specified IP address range without authentication. |             |
| <b>Configuration Examples</b> | The following example sets the IP address 172.16.0.1 as the authentication-exempted ARP resource.                                                                                                                     |             |
| <b>Examples</b>               | <pre>Ruijie(config)# http redirect direct-arp 172.16.0.1</pre>                                                                                                                                                        |             |
| <b>Related Commands</b>       | Command                                                                                                                                                                                                               | Description |
|                               | N/A                                                                                                                                                                                                                   | N/A         |
| <b>Platform Description</b>   | N/A                                                                                                                                                                                                                   |             |

## 5.10 http redirect direct-site

Use this command to set the range of authentication-exempted network resources.

Use the **no** form of this command to restore the default setting.

**http redirect direct-site** { *ipv6-address* | *ipv4-address* [ *ip-mask* ] [ **arp** ] | *mac-address* | range *startip-address endip-address* } [description *description-str*] [group *group-name*]

**no http redirect direct-site** { *ipv6-address* | *ipv4-address* [ *ip-mask* ] | *mac-address* | range *startip-address endip-address* }

### Parameter Description

| Parameter              | Description                                                                                                                                                                                               |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv6-address</i>    | IPv6 address of the authentication-exempted network resources                                                                                                                                             |
| <i>ip-address</i>      | IPv4 address of the authentication-exempted network resources                                                                                                                                             |
| <i>ip-mask</i>         | IPv4 address mask of the authentication-exempted network resources (optional)                                                                                                                             |
| <b>arp</b>             | If the ARP Check is enabled on the access device, the keyword arp is needed for ARP binding of the authentication-exempted network resources (optional). It is necessary for IPv4 network resources only. |
| <i>mac-address</i>     | MAC address of the authentication-exempted user                                                                                                                                                           |
| <i>startip-address</i> | Start IP address of the authentication-exempted user                                                                                                                                                      |
| <i>endip-address</i>   | End IP address of the authentication-exempted user                                                                                                                                                        |
| <i>group-name</i>      | Group name of the authentication-exempted user                                                                                                                                                            |
| <i>description-str</i> | Description of the authentication-exempted user                                                                                                                                                           |

**Defaults** No authentication-exempted network resource is set.

**Command** Global configuration mode

**Mode**

**Usage Guide** When Web/802.1x authentication is enabled, all users must pass Web/client authentication to access network resources. This command is used to make certain network resources available to unauthenticated users. All users can access the authentication-exempted Web sites. Up to 50 authentication-exempted users are supported.

**Configuration Examples** The following example sets the Web site with IP address 172.16.0.1 as the authentication-exempted resource.

```
Ruijie(config)# http redirect direct-site 172.16.0.1
```

The following example sets the Web site with MAC address 0000:5e00:0101 as the authentication-exempted resource.

```
Ruijie(config)# http redirect direct-site 0000:5e00:0101
```

The following example sets the range from 10.0.0.1 to 12.0.0.1 as authentication-exempted network resources.

```
Ruijie(config)# http redirect direct-site range 10.0.0.1 12.0.0.1
```

**Related  
Commands**

| Command                   | Description                                  |
|---------------------------|----------------------------------------------|
| <b>show http redirect</b> | Displays the HTTP redirection configuration. |

**Platform** N/A  
**Description**

## 5.11 http redirect port

Use this command to redirect users' HTTP redirection request to a certain destination port.

Use the **no** form of this command to restore the default setting.

**http redirect port** *port-num*

**no http redirect port** *port-num*

**Parameter  
Description**

| Parameter       | Description                          |
|-----------------|--------------------------------------|
| <i>port-num</i> | Destination port of the HTTP request |

**Defaults** The default is port 80.

**Command  
Mode** Global configuration mode

**Usage Guide** When you access the network resource, you send HTTP packets. The access device can intercept such HTTP packets to detect your access. If the access device detects that an unauthenticated user is accessing the network resource, it stops the users with an authentication page/client download page.

By default, the access device intercepts users' HTTP packets with port 80 to check whether they are accessing network resources.

This command is used to change the destination port of HTTP packets that are intercepted by the access device.

Up to 10 ports can be configured, excluding port 80 and port 443.

**Configuration** The following example redirects users' HTTP requests with port 8080.

**Examples**

```
Ruijie(config)# http redirect port 8080
```

The following example does not redirect users' HTTP requests with port 80.

```
Ruijie(config)# no http redirect port 80
```

**Related  
Commands**

| Command                   | Description                                  |
|---------------------------|----------------------------------------------|
| <b>show http redirect</b> | Displays the HTTP redirection configuration. |

**Platform** N/A  
**Description**

## 5.12 http redirect session-limit

Use this command to set the total number of HTTP sessions that can be originated by an unauthenticated user, or the maximum number of HTTP sessions that can be originated by an unauthenticated user connected to each port.

Use the **no** form of this command to restore the default setting.

**http redirect session-limit** *session-num* [ **port** *port-session-num* ]

**no http redirect session-limit**

| Parameter Description | Parameter               | Description                                                                                                                                 |
|-----------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>session-num</i>      | Total number of HTTP sessions that can be originated by an unauthenticated user, in the range from 1 to 255.                                |
|                       | <i>port-session-num</i> | The maximum number of HTTP sessions that can be originated by an unauthenticated user connected to each port, in the range from 1 to 65535. |

**Defaults** Totally 255 HTTP sessions can be originated by an unauthenticated user, and 300 HTTP sessions that can be originated by an unauthenticated user connected to each port.

**Command Mode** Global configuration mode

**Usage Guide** To prevent HTTP attacks caused by unauthenticated users from using up the TCP connections of the access device, the maximum number of HTTP sessions by unauthenticated users must be limited on the access device.

In addition to authentication, other programs may also occupy HTTP sessions. Therefore, it is not recommended that the maximum number of HTTP sessions by unauthenticated users be 1

**Configuration Examples** The following example sets the maximum number of HTTP sessions originated by an unauthenticated user to 4.

```
Ruijie(config)# http redirect session-limit 4
```

| Related Commands | Command                   | Description                                  |

**Description**

## 5.13 http redirect timeout

Use this command to set the timeout for the redirection connection maintenance.

Use the **no** form of this command to restore the default setting.

**http redirect timeout** *seconds*

**no http redirect timeout**

| Parameter<br>Description | Parameter      | Description                                                                                                   |
|--------------------------|----------------|---------------------------------------------------------------------------------------------------------------|
|                          | <i>seconds</i> | Set the timeout for the redirection connection maintenance, in the range from 1 to 10 in the unit of seconds. |

**Defaults** The default is 3 seconds.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to set the timeout for the redirection connection maintenance. After the three-way handshake succeeds, the redirection connection is maintained until the user sends an HTTP GET/HEAD packet and the system returns an HTTP redirection packet. This timeout is set to prevent users from occupying TCP connections for long without sending any GET/HEAD packets.

**Configuration** The following example sets the timeout for the redirection connection maintenance to 4 seconds.

**Examples** Ruijie(config)# http redirect timeout 4

|                     | <b>show http redirect</b> | Displays the HTTP redirection configuration. |

**Platform Description** N/A

## 5.14 ip

Use this command to set an IP address for the portal server.

Use the **no** form of this command to restore the default setting.

**port** { *ip-address* }

**no port**

| Parameter<br>Description | Parameter         | Description                           |
|--------------------------|-------------------|---------------------------------------|
|                          | <i>ip-address</i> | The IPv4 address of the portal server |

**Defaults** No IP address is set for the portal server by default.

**Command Mode** Template configuration mode

**Usage Guide** This command takes place of the **http redirect** [*ip-address*] command, which is now hidden as a compatible command.

**Configuration** The following example sets the IP address of the eportalv1 template to 172.16.0.1.

```
Ruijie(config.tmplt.eportalv1)#ip 172.16.0.1
Ruijie(config.tmplt.eportalv1)#
```

**Related Commands**

## 5.15 ip portal source-interface

Use this command to specify a communication port for the portal server.

Use the **no** form of this command to restore the default setting.

**ip portal source-interface** *interface-type interface-num*

**no ip portal source-interface**

**Parameter Description**

| Parameter             | Description |
|-----------------------|-------------|
| <i>interface-type</i> | Port type   |
| <i>interface-num</i>  | Port No.    |

**Defaults** No communication interface is specified by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration** The following example specifies an aggregate port as the communication port.

```
Ruijie (config)# ip portal source-interface Aggregateport 1
```

**Platform Description** N/A

## 5.16 port

Use this command to set a surveillance port for the portal server.

Use the **no** form of this command to restore the default setting.

**port** { *port-num* }

**no port**

| Parameter Description | Parameter   | Description                                                                                    |
|-----------------------|-------------|------------------------------------------------------------------------------------------------|
|                       | <i>port</i> | The surveillance port of the portal server, which is on only the 2nd generation portal server, |

**Defaults** The default is 50100 based on the UDP protocol.

**Command Mode** Template configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the surveillance port number of the eportalv2 server to 10000.

```
Ruijie(config.tmplt.eportalv2)#port 10000
```

| Related Commands | Command | Description |

## 5.17 redirect

Use this command to specify the encapsulation format of the Web-auth URL.

**redirect** { *http* | *js* }

**no redirect**

| Parameter Description | Parameter   | Description                      |
|-----------------------|-------------|----------------------------------|
|                       | <i>http</i> | HTTP encapsulation format        |
|                       | <i>js</i>   | Java Script encapsulation format |

**Defaults** The default encapsulation format is Java Script.

**Command** Template configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example specifies HTTP as the encapsulation format of the Web-auth URL.

**Examples** Ruijie(config.tmplt.eportalv2)#redirect http

**Platform**  
**Description** N/A

## 5.18 show web-auth acl

Use this command to display whitelist configuration.

**show web-auth acl [white-url ]**

**Parameter**  
**Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Command** Privileged EXEC mode  
**Mode**

**Usage Guide** The command is used to check the whitelist configuration of web authentication.

**Configuration** The following example displays whitelist configuration.

**Examples** Ruijie# show web-auth acl

```
White URL List:0
-----
```

**Platform**  
**Description** N/A

## 5.19 show web-auth authmng

Use this command to display authentication experience data.

**show web-auth authmng [statistic | abnormal]**

**Parameter**  
**Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|     |     |
|-----|-----|
| N/A | N/A |
|-----|-----|

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays authentication experience data.

**Examples** Ruijie# show web-auth authmng statistic

The following example displays abnormal authentication experience data.

```
Ruijie# show web-auth authmng abnormal
record num:0, value:3000, max-num:1000, clock:1
```

| Field      | Description                                                                                                              |
|------------|--------------------------------------------------------------------------------------------------------------------------|
| record num | Number of records.                                                                                                       |
| value      | Timeout period in the unit of ms. By default, one abnormal record is generated when the timeout exceeds 3s.              |
| max-num    | Maximum number of records.                                                                                               |
| clock      | The time when the record is written into flash in the range from 0 o'clock to 23 o'clock. The default time is 1 o'clock. |

Abnormal records are stored in the directory: /data/security/authmanage/webauth/.

**Platform Description** N/A

## 5.20 show web-auth control

Use this command to display the authentication configuration.

**show web-auth control**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the authentication configuration and statistics information on the interface.

```
Ruijie(config)#show web-auth control
Port                Control  Server Name          Online User Count
-----
GigabitEthernet 0/1  On      <not configured>    0
Ruijie(config)#
```

| Field             | Description                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------|
| Port              | Name of the authentication port.                                                                                         |
| Control           | Displays whether the Web authentication is enabled on the port or not.                                                   |
| Server Name       | The customized server name on the port. <b>&lt;not configured&gt;</b> indicates the server name has not been configured. |
| Online User Count | The number of online users on this port.                                                                                 |

**Description**

## 5.21 show web-auth direct-arp

Use this command to display the address range of the authentication-exempted ARP.

**show web-auth direct-arp**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** | N/A

**Configuration Examples** The following example displays the address range of the authentication-exempted ARP.

```
Ruijie(config)#show web-auth direct-arp
Direct arps:
Address      Mask
-----
1.1.1.1      255.255.255.255
2.2.2.2      255.255.255.255
```

```
Ruijie (config) #
```

| Field   | Description   |
|---------|---------------|
| Address | IPv4 address. |
| Mask    | IPv4 mask.    |

## 5.28 show web-auth template

Use this command to display the portal server configuration.

**show web-auth template**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

N/A

**Command Mode**

Privileged EXEC mode

**Usage Guide**

Use this command to display the portal server configuration.

**Configuration**

The following example displays the port server configuration.

**Examples**

```
Ruijie#show web-auth template
Webauth Template Settings:
-----
Name:      eportalv1
Url:       http://17.17.1.21:8080/eportal/index.jsp
Ip:        17.17.1.21
BindMode:  ip-mac-mode
Type:      v1
-----
Name:      eportalv2
Url:       http://17.17.1.21:8080/eportal/index.jsp
Ip:        17.17.1.21
BindMode:  ip-only-mode
Type:      v2
Port:      50100
Acctmlist:
Authmlist:
Ruijie#
```

| Field     | Description                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------|
| Name      | Template name.                                                                                                               |
| Url       | Server homepage address.                                                                                                     |
| Ip        | Server IP address.                                                                                                           |
| Type      | Server type, including the first generation portal server v1, the second generation portal server v2, and internal is intra. |
| Port      | The protocol packet communication port of the server, which is on only the second generation portal server.                  |
| Acctmlist | Accounting method list name, which is on the second generation portal and internal servers.                                  |
| Authmlist | Authentication method list name. which is on only the second generation portal and internal servers.                         |

## 5.29 show web-auth user

Use this comma to display the online information, including IP address, interface, and online duration, of all users or the specified users.

**show web-auth user** { all | ip *ip-address* | mac *mac-address* | name *name-string* }

| Parameter Description | Parameter          | Description               |
|-----------------------|--------------------|---------------------------|
|                       | <i>ip-address</i>  | IPv4 address of the user. |
|                       | <i>mac-address</i> | MAC address of the user.  |
|                       | <i>name-string</i> | User name.                |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the global Web authentication configuration and statistics.

```
Ruijie# show web-auth user all
Current user num : 4, online 2
```

| Address      | Online | Time Limit  | Time Used   | Status  | Name |
|--------------|--------|-------------|-------------|---------|------|
| 192.168.0.11 | On     | 0d 01:00:00 | 0d 00:15:10 | Active  |      |
| 192.168.0.13 | On     | 0d 01:00:00 | 0d 00:00:59 | Active  | 111  |

## 5.30 url

Use this command to set the portal server URL.

Use the **no** form of this command to restore the default setting.

**url** *url-string*

**no url**

**Parameter Description**

| Parameter         | Description                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>url-string</i> | Portal server URL, starting with <b>http://</b> or <b>https://</b> . The maximum length of this address is 255 bytes. |

**Defaults**

On the first/second/inner/wifidog auth, no portal server URL is set by default.

On WeChat auth, the URL when MCP/WMC server adopts WeChat and MSG auth by default.

**Command Mode**

Template configuration mode

**Usage Guide**

This command takes place of the **http redirect homepage** [ *url-string* ] command, which is now hidden as a compatible command.,

If no URL is specified, the default URL in the **http://[ ip-address ]** format will be adopted, among which **ip-address** is the IP address of the server.

**Configuration Examples**

The following example sets the eportalv1 template URL to **http://www.web-auth.net/login**.

**Examples**

```
Ruijie(config.tmplt.eportalv1)#url http://www.web-auth.net/login
```

## 5.31 web-auth acl

The whitelist users can access partial network resources before auth, and the blacklist users can not access partial network resources after auth. Use **no** form of this command to restore the default setting.

**web-auth acl** {white-url name }

**no web-auth acl** { white-url name }

| Parameter Description | Parameter | Description   |
|-----------------------|-----------|---------------|
|                       | name      | Whitelist URL |

**Command Mode** Global configuration mode

**Usage Guide** The command is used to check the whitelist configuration of web authentication.

**Configuration** The following example configures whitelist.

**Examples** Ruijie (config)# web-auth acl white-url www.ruijie.com.cn

**Platform Description** N/A

## 5.32 web-auth dhcp-check

Use this command to enable DHCP IP address check.

Use **no** form of this command to restore the default setting.

**web-auth dhcp-check**

**no web-auth dhcp-check**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** DHCP IP address check is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Only users whose IP addresses are allocated by DHCP are allowed to take authentication.

**Configuration** The following example enables DHCP IP address check.

**Examples** `Ruijie (config)# web-auth dhcp-check`

**Platform** N/A  
**Description**

### 5.33 web-auth dhcp-check vlan

Use this command to check whether the IP address of a client is assigned by the DHCP server.  
 Use the **no** form of this command to restore the default setting.

**web-auth dhcp-check {vlan [vlan-list]}**  
**no web-auth dhcp-check**

**Parameter**  
**Description**

| Parameter | Description                                                                            |
|-----------|----------------------------------------------------------------------------------------|
| vlan-list | Indicates the VLAN range in which DHCP address check needs to be enabled in interface. |

**Defaults** By default, this function is disabled.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example checks whether the IP address of a client is assigned by the DHCP server.

**Examples** `Ruijie(config-if-TenGigabitEthernet 3/1)# web-auth dhcp-check vlan 1,3-4`

| <b>Parameter Description</b> | <b>Parameter</b>                  | <b>Description</b>                                                                                                                                                                              |
|                              | <i>ip-address</i>                 | IPv4 address of authentication-exempted user                                                                                                                                                    |
|                              | <i>ip-mask</i>                    | Mask of the IPv4 address free of authentication (optional).                                                                                                                                     |
|                              | <b>port</b> <i>interface-name</i> | Binds user's IP address with a port of the access device (optional).                                                                                                                            |
|                              | <b>arp</b>                        | If ARP CHECK is enabled on the access device, keyword arp is needed for ARP binding of the IP address used by users free of authentication (optional). It is necessary for IPv4 addresses only. |

**Defaults** No user is exempted from authentication. All users must pass the Web authentication to access the restricted network resources.

**Command Mode** Global configuration mode

**Usage Guide** When a user is set to be exempted from authentication, it can access all reachable network resources

without Web authentication.

Up to 50 users can be set to be exempted from authentication.

**Configuration Examples** The following example sets the user with the IP address 172.16.0.1 to be exempted from authentication.

```
Ruijie(config)# web-auth direct-host 172.16.0.1
```

The following example sets the user with the IP address FF02::/64 to be exempted from authentication.

```
Ruijie(config)# web-auth direct-host FF02::/64
```

**Description**

## 5.36 web-auth enable

Use this command to enable the Web authentication function on a port. This command is compatible with the **web-auth port-control** command.

Use the **no** form of this command to restore the default setting.

**web-auth enable [ eportalv1 | eportalv2 | *template-name* ]**

**no web-auth enable**

**Parameter Description**

| Parameter            | Description                                            |
|----------------------|--------------------------------------------------------|
| <b>eportalv1</b>     | Applies the first generation authentication template.  |
| <b>eportalv2</b>     | Applies the second generation authentication template. |
| <i>template-name</i> | Customized template.                                   |

**Defaults** The Web authentication function is disabled on the port by default.  
 The **default** template is eportalv1.

**Command Mode** Interface configuration mode

**Usage Guide** To ensure the Web authentication function, the authentication page URL should be configured. Because template applications are integrated into the controlled switch, the template or the server applications of the interface where the Web authentication function is disabled will be automatically cleared. This command is compatible with the original command that used to apply the template or server application in the global configuration mode.

**Configuration** The following example enables the Web authentication function on gigabitEthernet 0/14.

**Examples**

```
Ruijie(config)# interface GigabitEthernet 0/14
Ruijie(config-if-GigabitEthernet 0/14)# web-auth enable
```

## 5.38 web-auth logging enable

Use this command to enable the Web authentication syslog function.

Use the **no** form of this command to restore the default setting.

**web-auth logging enable { num }**  
**no web-auth logging enable**

**Parameter  
Description**

| Parameter  | Description                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>num</i> | The syslog printing rate, indicating how many syslog entries can be printed in a second. The value is in the range from 0 to 65535. 0 indicates no limit. |

**Defaults** This function is disabled by default.

**Command  
Mode** Global configuration mode

**Usage Guide** This command is used to limit the syslog printing rate for only the functional module.

**Configuration** The following example enables the syslog printing with no rate limit.

**Examples** Ruijie(config)# web-auth logging enable 0

|  |                                                                    |
|--|--------------------------------------------------------------------|
|  | authentication server. The maximum length of the key is 255 bytes. |
|--|--------------------------------------------------------------------|

**Defaults** No key is set by default.

**Command Mode** Global configuration mode

**Usage Guide** To use the Web authentication function, the communication key between the access device and the authentication server must be set.

**Configuration Examples** The following example sets the communication key between the access device and the authentication server to web-auth.

```
Ruijie(config)# web-auth portal key web-auth
```

**Platform** N/A

**Description**

## 5.42 web-auth portal-check

Use this command to enable portal server check.

Use the **no** form of this command to restore the default setting.

**web-auth portal-check [ interval *intsec* ] [ timeout *tosec* ] [ retransmit *retires* ]**

**no web-auth porta-check**

**Parameter Description**

| Parameter      | Description                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------|
| <i>intsec</i>  | Check interval in the range from 1 to 1,000 in the unit of seconds.<br>The default is 10 seconds.  |
| <i>tosec</i>   | Timeout interval in the range from 1 to 1,000 in the unit of seconds.<br>The default is 5 seconds. |
| <i>retires</i> | Retry count in the range from 1 to 100.<br>The default is 3.                                       |

**Defaults** Portal server check is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** It is recommended to use this command when there are multiple servers.

**Configuration** The following example enables portal server check.

**Examples** Ruijie (config)# web-auth portal-check interval 20 timeout 2 retransmit 2

**Platform**  
**Description** N/A

## 5.43 web-auth portal-escape

Use this command to enable portal-escape function.

Use the **no** form of this command to restore the default setting.

**web-auth portal-escape**

**no web-auth portal-escape**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** This function is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** Use this command together with **web-auth portal-check** command to sustain key services when the portal server is abnormal.

**Configuration** The following example enables portal-escape function.

**Examples** Ruijie (config)# web-auth portal-escape

**Platform**  
**Description** N/A

## 5.44 web-auth template

Use this command to create the first generation authentication template and enter its configuration mode.

**web-auth template eportalv1**

Use this command to create the customized first generation authentication template and enter its

configuration mode.

**web-auth template** { template-name } v1

Use this command to create the second generation authentication template and enter its configuration mode.

**web-auth template eportalv2**

Use this command to create the customized second generation authentication template and enter its configuration mode.

**web-auth template** { template-name } v2

Use this command to remove the template.

**no web-auth template** { template-name }

**Parameter  
Description**

| Parameter            | Description                                              |
|----------------------|----------------------------------------------------------|
| <b>eportalv1</b>     | Applies the first generation authentication template.    |
| <b>eportalv2</b>     | Applies the second generation authentication template.   |
| <i>template-name</i> | Sets the name of the customized authentication template. |

**Defaults**

No template is configured by default.

**Command  
Mode**

Global configuration mode

**Usage Guide**

You can enter the **eportalv1** template mode to configure the IP address and URL instead of executing the **http redirect** and **http redirect homepage** commands. The **http redirect** and **http redirect homepage** commands are compatible on the device, which will be converted to this command.

The original command **portal-server** is compatible on the device, which will be converted to this command.

To ensure the Web authentication function, configure and apply a functional portal server. The **eportalv1** template is applied by default. The IP address, the URL and the communication secret key of the **eportalv1** template should be configured. If no URL format is specified, the default **http://[ ip-address ]** format will be adopted. The IP address of the portal server is the network resource exempted from authentication, so the unauthenticated user can access it. The device limits the uplink traffic that accesses the IP address to prevent attacks. The upper limit is proportionate to the number of the physical ports.

**Configuration**

The following example configures the **eportalv1** template.

**Examples**

```
Ruijie(config)# web-auth template eportalv1
Ruijie(config.tmplt.eportalv1) #
```

**Defaults** The default is port-control authentication.

**Command** Interface configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** Use this command to configure the authenticable VLAN list.

**Examples** Ruijie (config-if-GigabitEthernet 0/1)# web-auth vlan-control 1

**Platform** N/A  
**Description**

## 6 SCC Commands

### 6.1 Identifier Description

The following is a list of command identifiers used in commands for reference:

| Identifier | Description                                                         |
|------------|---------------------------------------------------------------------|
| vlanlist   | Authentication-exemption VLAN list                                  |
| interval   | Authenticated-user online-status detection interval                 |
| thredshold | The traffic threshold of authenticated-user online-status detection |

### 6.2 authmanage user-escape

Use this command to enable user escape.

**authmanage user-escape** { **enable** | **time** *time-value1* | **when authentication-time** *time-value2* | **when timeout-ratio** *ratio-number* | **life** *life-value* }

Use this command to disable user escape.

**no authmanage user-escape** { **enable** | **time** | **when authentication-time** | **when timeout-ratio** | **life** }

|                                        |                    |                                                                                                                                                                                  |
|----------------------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameter</b><br><b>Description</b> | <b>Parameter</b>   | <b>Description</b>                                                                                                                                                               |
|                                        | <i>time-value1</i> | Indicates the escape duration, in the unit of minutes.                                                                                                                           |
|                                        | <i>time-value2</i> | Indicates the authentication duration, in the unit of ms. When the value exceeds that of <i>time-value2</i> , part of users is allowed to escape for <i>time-value1</i> minutes. |

|                     |                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ratio-number</i> | When the ratio of authenticated users exceeds the value of <i>ratio-number</i> , part of users is allowed to escape for <i>time-value1</i> minutes. |
| <i>life-value</i>   | Indicates the escape lifetime, in the unit of minute.                                                                                               |

**Defaults**

*time-value1*: The value is 30 minutes by default and can be set to 10 minutes to 240 minutes.

*time-value2*: The default value is 5,000, which indicates that part of users are allowed to escape when the average handling duration exceeds 5s. The value ranges from 1,000 to 10,000.

*ratio-number*: The default value is 10, which indicates that the part of users are allowed to escape when the ratio of timeout authentication users exceed 10%. The value ranges from 1 to 100.

*life-value*: The value is 30 minutes by default and can be set to 10 minutes to 240 minutes.

**Command**

Global configuration mode

**Mode****Default Level**

14

**Usage Guide**

User escape needs to be enabled only when the system is detected to fail timely authentication.

**Configuration**

The following example enables user escape in global configuration mode.

**Examples**

```
Ruijie(config)# authmanage user-escape enable
```

**Verification**

Run **show authmanage user-escape** to display user escape configuration.

**Prompt****Messages**

N/A

**Common****Errors**

N/A

**Platforms**

This command is supported only on switches.

## 6.3 direct-vlan

Use this command to configure authentication-exemption VLANs.

**direct-vlan** *vlanlist*

Use this command to delete the authentication-exemption VLAN configuration.

**no direct-vlan** *vlanlist*

**Parameter Description**

| Parameter       | Description                                         |
|-----------------|-----------------------------------------------------|
| <i>vlanlist</i> | VLAN list, which can be a VLAN or a group of VLANs. |

|                               |                                                                                                                                                                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>               | By default, no authentication-exemption VLANs are configured.                                                                                                                                                                                                                                               |
| <b>Command Mode</b>           | Global/Interface configuration mode                                                                                                                                                                                                                                                                         |
| <b>Default Level</b>          | 14                                                                                                                                                                                                                                                                                                          |
| <b>Usage Guide</b>            | You can use this command to configure authentication-exemption VLANs, so that users in specified VLANs can access the Internet without experiencing dot1x or Web authentication.<br>In interface configuration mode, the command takes effect on users from authentication-exempted VLANs of the interface. |
| <b>Configuration Examples</b> | The following example configures the VLAN2 as an authentication-exemption VLAN.                                                                                                                                                                                                                             |
| <b>Examples</b>               | <pre>Ruijie(config)# direct-vlan 2</pre>                                                                                                                                                                                                                                                                    |
| <b>Verification</b>           | Use the <b>show direct-vlan</b> command to display the authentication-exemption VLAN configuration.                                                                                                                                                                                                         |
| <b>Prompt Messages</b>        | N/A                                                                                                                                                                                                                                                                                                         |
| <b>Common Errors</b>          | N/A                                                                                                                                                                                                                                                                                                         |

## 6.4 nac-author-user maximum

Use this command to configure the limit on IPv4 user capacity on a port.

**nac-author-user maximum** *max-user-num*

Use this command to remove the limit on the IPv4 user capacity on a port.

**no nac-author-user maximum**

| Parameter Description | Parameter           | Description                                                                    |
|-----------------------|---------------------|--------------------------------------------------------------------------------|
|                       | <i>max-user-num</i> | Defines the maximum number of IPv4 access users. The range is from 1 to 1,024. |

**Defaults** By default, the number of IPv4 access users is not limited.

**Command Mode** Interface configuration mode

**Default Level** 14

**Usage Guide** Use this command to configure the maximum number of IPv4 access users on a port.

**Configuration** The following example restricts the maximum number of IPv4 users to 100 on interface Gi 0/1.

**Examples**

```
Ruijie(config)#int gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#nac-author-user maximum 100
```

**Verification**

1. Use the **show nac-author-user** command to display the current and the maximum numbers of IPv4 access users on all ports.
2. Use the **show nac-author-user interface interface-name** command to display the current and the maximum numbers of IPv4 access users on the specified port.

**Prompt Messages** N/A

**Common Errors** N/A

**Platforms** N/A

## 6.5 offline-detect interval threshold

Use this command to configure user online-status detection, so that a user is disconnected when its traffic is lower than a specified threshold or is zero in a specified interval.

**offline-detect interval interval threshold threshold**

Use this command to restore the default user online-status detection configuration.

**default offline-detect**

Use this command to disable user online-status detection.

**no offline-detect**

**Parameter Description**

| Parameter        | Description                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>interval</i>  | Indicates the interval of traffic detection (in minutes). The range is from 1 to 65,535 in minutes on a non-switch device or from 6 to 65,535 in minutes on a switch.                      |
| <i>threshold</i> | Indicates the traffic threshold (in bytes). The range is from 0 to 4,294,967,294 in bytes. The value of 0 indicates that the user is disconnected when no traffic of the user is detected. |

**Defaults** By default, the detection interval is 8 hours and the traffic threshold is 0.

|                               |                                                                                                                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                                                              |
| <b>Default Level</b>          | 14                                                                                                                                                                                                     |
| <b>Usage Guide</b>            | You can use this command to configure user online-status detection to enable the device to disconnect the authenticated user whose traffic is lower than a specified value and end accounting process. |
| <b>Configuration Examples</b> | The following example directly disconnects a user for the user's traffic is lower than 5 Kbytes within 5 minutes.<br><pre>Ruijie(config)#offline-detect interval 5 threshold 5120</pre>                |
| <b>Verification</b>           | Use the <b>show running</b> command to display the configuration of online-status detection for authenticated users.                                                                                   |
| <b>Prompt Messages</b>        | N/A                                                                                                                                                                                                    |
| <b>Common Errors</b>          | N/A                                                                                                                                                                                                    |
| <b>Platforms</b>              | N/A                                                                                                                                                                                                    |

## 6.6 show direct-vlan

Use this command to display the authentication-exemption VLAN configuration.

**show direct-vlan**

|                               |                                                                                                                                            |                    |

## 7 Global IP-MAC Binding Commands

### 7.1 address-bind

Use this command to configure global IP-MAC address binding. Use the **no** form of this command to restore the default setting.

**address-bind** { *ip-address* | *ipv6-address* } *mac-address*

**no address-bind** { *ip-address* | *ipv6-address* } *mac-address*

| Parameter   | Parameter           | Description              |
|-------------|---------------------|--------------------------|
| Description | <i>ip-address</i>   | IPv4 address to be bound |
|             | <i>ipv6-address</i> | IPv6 address to be bound |
|             | <i>mac-address</i>  | MAC address to be bound  |

**Defaults** N/A

**Command** Global configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example configures global IP-MAC address binding.

**Examples**

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# address-bind 192.168.5.1 00d0.f800.0001
```

| Related Commands | Command                  | Description                                        |
|------------------|--------------------------|----------------------------------------------------|
|                  | <b>show address-bind</b> | Displays the IP address-MAC address binding table. |

**Platform** N/A

**Description**

### 7.2 address-bind install

Use this command to enable a binding policy globally. Use the **no** form of this command to restore the default setting.

**address-bind install**

**no address-bind install**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |     |     |
|--------------------|-----|-----|
| <b>Description</b> | N/A | N/A |
|--------------------|-----|-----|

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** If you bind an IP address to a MAC address, run this command to make the installation policy take effect.

**Configuration** The following example enables a binding policy.

**Examples**

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# address-bind 192.168.5.1 00d0.f800.0001
Ruijie(config)# address-bind install
```

| <b>Related Commands</b> | <b>Command</b> | <b>Description</b> |
|-------------------------|----------------|--------------------|
|                         | N/A            | N/A                |

**Platform Description** N/A

## 7.3 address-bind ipv6-mode

This command is used to set the IPv6 address binding mode. Use the **no** form of this command to restore the default setting.

This command is also used to set the compatible mode.

**address-bind ipv6-mode { compatible | loose | strict }**

**no address-bind ipv6-mode**

| <b>Parameter Description</b> | <b>Parameter</b>  | <b>Description</b> |
|------------------------------|-------------------|--------------------|
|                              | <b>compatible</b> | Compatible mode    |
|                              | <b>loose</b>      | Loose mode         |
|                              | <b>strict</b>     | Strict mode        |

**Defaults** The default is strict mode.

**Command Mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example configures the IPv6 address binding mode.

**Examples**

```
Ruijie# configure terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# address-bind ipv6-mode compatible
```

| Related Commands | Command                         | Description                                           |
|------------------|---------------------------------|-------------------------------------------------------|
|                  | <b>show address-bind uplink</b> | Displays the exceptional port of the address binding. |

**Platform** N/A

**Description**

## 7.4 address-bind uplink

This command is used to configure the exception port. Use the **no** form of this command to restore the default setting.

**address-bind uplink** *interface-id*

**no address-bind uplink** *interface-id*

| Parameter          | Parameter           | Description                               |
|--------------------|---------------------|-------------------------------------------|
| <b>Description</b> | <i>interface-id</i> | Switching port or layer 2 aggregate port. |

**Defaults** All ports are non-exception ports by default.

**Command Mode** Global configuration mode.

**Usage Guide** If you have bound an IP address and a MAC address, the switch will discard the packets that have the same source IP address but different source MAC address.

If the port is an exceptional port and is installed (see address-bind install), this binding policy does not take effect.

**Configuration** The following example configures the exception port.

**Examples**

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# address-bind uplink GigabitEthernet 0/1
```

| Related Commands | Command                         | Description                                       |
|------------------|---------------------------------|---------------------------------------------------|
|                  | <b>show address-bind uplink</b> | Displays the exceptional port of address binding. |

**Platform** N/A

**Description**

## 7.5 show address-bind

Use this command to display global IP address-MAC address binding.

**show address-bind**

|                     |                       |                    |
|---------------------|-----------------------|--------------------|
| <b>Parameter</b>    | <b>Parameter</b>      | <b>Description</b> |
| <b>Description</b>  | N/A                   | N/A                |
| <b>Defaults</b>     | N/A                   |                    |
| <b>Command Mode</b> | Privileged EXEC mode. |                    |
| <b>Usage Guide</b>  | N/A                   |                    |

**Configuration** The following example displays global IPv4 address-MAC address binding.

**Examples**

```
Ruijie#show address-bind
Total Bind Addresses in System : 1
IP Address          Binding MAC Addr
-----
192.168.5.1        00d0.f800.0001
```

| Field                          | Description                            |
|--------------------------------|----------------------------------------|
| Total Bind Addresses in System | IPv4 address-MAC address binding count |
| IP Address                     | Bound IP address                       |
| Binding MAC Addr               | Bound MAC address                      |

**Platform** N/A  
**Description**

## 7.6 show address-bind uplink

Use this command to display the exception port.

**show address-bind uplink**

|                     |                  |                    |
|---------------------|------------------|--------------------|
| <b>Parameter</b>    | <b>Parameter</b> | <b>Description</b> |
| <b>Description</b>  | N/A              | N/A                |
| <b>Defaults</b>     | N/A              |                    |
| <b>Command mode</b> | N/A              |                    |
| <b>Usage Guide</b>  | N/A              |                    |

**Configuration** The following example displays the exception port.

**Examples**

```
Ruijie#show address-bind uplink
Port      State
-----  -
Gi0/1     Enabled
Default   Disabled
```

| Field | Description                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Port  | Short for exception ports. All ports are non-exception ports by default.                                                                          |
| State | Indicates whether the port is exception port. State Enabled indicates that it is an exception port while state Disabled indicates that it is not. |

**Related****Commands**

**Description**

## 8 Password-Policy Commands

### 8.1 password policy life-cycle

Use this command to set the password lifecycle. Use the **no** form of this command to restore the default setting.

**password policy life-cycle** *days*

**no password policy life-cycle**

| Parameter Description | Parameter   | Description                                                                     |
|-----------------------|-------------|---------------------------------------------------------------------------------|
|                       | <i>days</i> | Sets the password lifecycle, in the range from 1 to 65,535 in the unit of days. |

**Defaults** No password lifecycle is set by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is used to set the password lifecycle. After the password lifecycle expires, the system reminds you to change the password when you login next time.

 This function is valid for the global password (the `enable password` and the `enable secret` commands) and the local user password (the `username name password password` command) while not valid for the password in line mode.

**Configuration Examples** The following example sets the password lifecycle to 90 days.

```
Ruijie(config)# password policy life-cycle 90
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

### 8.2 password policy min-size

Use this command to set the minimum length of the password. Use the **no** form of this command to restore the default setting.

**password policy min-size** *length*

**no password policy min-size**

| Parameter<br>Description | Parameter | Description   |
|--------------------------|-----------|---------------|
|                          |           | <i>length</i> |

**Defaults** No minimum length of the password is set by default.

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to set the minimum length of the password,

-  This function is valid for the global password (the enable password and the enable secret commands) and the local user password (the username *name* password *password* command) while not valid for the password in line mode.

**Configuration** The following example sets the minimum length of the password to 8.

**Examples** Ruijie(config)# password policy min-size 8

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     |         | N/A         |

**Platform Description** N/A

### 8.3 password policy no-repeat-times

Use this command to ban the use of passwords used in the past several times. Use the no form of this command to restore the default setting.

**password policy no-repeat-times** *times*

**no password policy no-repeat-times**

| Parameter<br>Description | Parameter | Description  |
|--------------------------|-----------|--------------|
|                          |           | <i>times</i> |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** After this function is enabled, passwords used in the past several times are recorded. If the

new password has been used, the alarm message is displayed and password configuration fails.

This command is used to set the maximum number of password entries. When the actual number of password entries exceeds the configured number, the new password overwrites the oldest password.

 This function is valid for the global password (the `enable password` and the `enable secret` commands) and the local user password (the `username name password password` command) while not valid for the password in line mode.

#### Configuration

The following example bans the use of passwords used in the past five times.

#### Examples

```
Ruijie(config)# password policy no-repeat-times 5
```

#### Related Commands

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform Description** N/A

## 8.4 password policy strong

Use this command to enable strong password check.

**password policy strong**

**no password policy strong**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

#### Defaults

This function is disabled by default.

#### Command Mode

Global configuration mode

#### Usage Guide

If the following two kinds of passwords are set not matching the strength policy, the alarm message is displayed.

1. The password the same as the username.
2. The simple password containing only characters or numbers.

 This function is valid for the global password (the `enable password` and the `enable secret` commands) and the local user password (the `username name password password` command) while not valid for the password in line mode.

**Configuration** The following example configures the strong password check.

**Examples** `Ruijie(config)# password policy strong`

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 8.5 service password-encryption

Use this command to encrypt a password. Use the **no** form of this command to restore default setting.

**service password-encryption**

**no service password-encryption**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command is disabled by default. Various passwords are displayed in plain text, unless they are encrypted. After you run the **service password-encryption** and **show running** or **write** command to save your configuration, the password changes into cipher text. If you disable the command, the password in cipher text cannot be restored to plain text.

**Configuration** The following example encrypts the password:

**Examples** `Ruijie(config)# service password-encryption`

| Related Commands | Command                | Description                             |
|------------------|------------------------|-----------------------------------------|
|                  | <b>enable password</b> | Sets passwords of different privileges. |

**Platform Description** N/A

## 8.6 show password policy

Use this command to display the password security policy set by the user.

**show password policy**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display the password security policy set by the user.

**Configuration Examples** The following example displays the password security policy set by the user.

```
Ruijie#show password policy
Global password policy configurations:
Password encryption:           Enabled
Password strong-check:        Enabled
Password min-size:             Enabled (6 characters)
Password life-cycle:           Enabled (90 days)
Password no-repeat-times:      Enabled (max history record: 5)
```

| Field                    | Description                                        |
|--------------------------|----------------------------------------------------|
| Password encryption      | Whether to encrypt the password.                   |
| Password strong-check    | Whether to enable password strong-check.           |
| Password min-size        | Whether to set the minimum length of the password. |
| Password life-cycle      | Whether to set the password lifecycle.             |
| Password no-repeat-times |                                                    |

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 9 Port Security Commands

### 9.1 switchport port-security

Use this command to configure port security and the way to deal with violation.

Use the **no** form of this command to restore the default setting.

**switchport port-security** [ violation { protect | restrict | shutdown } ]

**no switchport port-security** [ violation ]

| Parameter Description | Parameter       | Description                                                                                     |
|-----------------------|-----------------|-------------------------------------------------------------------------------------------------|
|                       | <b>protect</b>  | Discards the packets breaching security.                                                        |
|                       | <b>restrict</b> | Discards the packets breaching security and sends the Trap message.                             |
|                       | <b>shutdown</b> | Discards the packets breaching the security, sends the Trap message and disables the interface. |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** With port security, you can strictly control the input on a specific port by restricting access to the MAC address and IP address (optional) of the port on the switch. After you configure some secure addresses for the port security-enabled port, only the packets from these addresses can be forwarded. In addition, you can also restrict the maximum number of secure addresses on a port. If you set the maximum value to 1 and configure one secure address for this port, the workstation (whose address is the configured secure Mac address) connected to this port will occupy all the bandwidth of this port exclusively.

 If the violation handling mode is changed after violation occurs, the new mode takes effect only after the violation mode is restarted.

**Configuration Examples** The following example enables port security on interface gigabitethernet 1/1, and the way to deal with violation is **shutdown**:

```
Ruijie(config)#interface gigabitethernet 1/1
Ruijie(config-if)# switchport port-security
Ruijie(config-if)# switchport port-security violation shutdown
```

| Related Commands | Command                   | Description                      |
|------------------|---------------------------|----------------------------------|
|                  | <b>show port-security</b> | Displays port security settings. |

**Platform** N/A

**Description**

## 9.2 switchport port-security aging

Use this command to set the aging time for all secure addresses on an interface.

Use the **no** form of this command to restore the default setting.

**switchport port-security aging {static | time *time* }**

**no switchport port-security aging {static | time }**

**Parameter  
Description**

| Parameter               | Description                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>static</b>           | Applies the aging time to both manually configured secure addresses and automatically learned addresses. Otherwise, apply it to only the automatically learned secure addresses. |
| <b>time <i>time</i></b> | Specifies the aging time for the secure address on this port. Its range is 0-1,440 in minutes. If you set it to 0, the aging function is disabled actually.                      |

**Defaults** No secure address is aged by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** In interface configuration mode, use the **no switchport port-security aging time** command to disable the aging for security addresses on the port. Use the **no switchport port-security aging static** command to apply the aging time to only the dynamically learned security address.

Use the **show port-security** command to display configuration.

When both port security and 802.1X authentication functions are enabled, 802.1X clients must get re-authenticated for network access once the secure addresses are aged.

 To enable this function, you need to set the maximum number of secure addresses. In this way, you can make the switch automatically add or delete the secure addresses on the interface.

**Configuration Examples** The following example sets the aging time for all secure addresses on interface gigabitethernet 1/1 to eight minutes.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if)# switchport port-security aging time 8
Ruijie(config-if)# switchport port-security aging static
Ruijie(config-if)# end
```

|---------|-------------|

| Commands                  |                                  |
|---------------------------|----------------------------------|
| <b>show port-security</b> | Displays port security settings. |

**Platform** N/A

**Description**

### 9.3 switchport port-security binding

Use these commands to configure secure address binding manually in the interface configuration mode through performing the source IP address plus source MAC address binding or only the source IP address binding. With this binding configured, only the packets match the binding secure address could enter the switch, others will be discarded.

Use the **no** form of these commands to remove the binding addresses.

**switchport port-security binding** [ *mac-address* **vlan** *vlan\_id* ] { *ipv4-address* | *ipv6-address* }

**switchport port-security binding** { *ipv4-address* | *ipv6-address* }

**no switchport port-security binding** [ *mac-address* **vlan** *vlan\_id* ] { *ipv4-address* | *ipv6-address* }

**no switchport port-security binding** { *ipv4-address* | *ipv6-address* }

| Parameter Description | Parameter           | Description                               |
|-----------------------|---------------------|-------------------------------------------|
|                       | <i>mac-address</i>  | The source MAC addresses to be bound      |
|                       | <i>vlan_id</i>      | VLAN ID of the binding source MAC address |
|                       | <i>ipv4-address</i> | Binds IPv4 addresses.                     |
|                       | <i>ipv6-address</i> | Binds IPv6 addresses.                     |

**Defaults** N/A

**Command Mode** Interface configuration mode

**Usage Guide**

1. For packets complying with IP/IP-MAC binding, they can be forwarded only if MAC addresses are secure addresses.
2. For dynamic secure addresses, packets cannot be forwarded before bound even if their addresses comply with the binding list.

 Network is often accessible to static users with secure addresses without authorization. If authorization is configured, these users must comply with it.

**Configuration Examples** The following example binds the IP address 192.168.1.100 on interface g 0/10:

```
Ruijie# configure terminal
Ruijie(config)#interface gigabitethernet 0/10
Ruijie(config-if)# switchport port-security binding 192.168.1.100
Ruijie(config-if)# end
```

The following example binds the IP address 192.168.1.100 and MAC address 00d0.f800.5555 with VLAN ID 1 on interface g 0/10.

```
Ruijie# configure terminal
Ruijie(config)#interface gigabitethernet 0/10
Ruijie(config-if)# switchport port-security binding 00d0.f800.5555 vlan 1
192.168.1.100
Ruijie(config-if)# end
```

#### Related Commands

| <b>switchport port-security</b>                   | Enables the port-security.                                     |
| <b>switchport port-security binding interface</b> | Configures the secure address binding in privileged EXEC mode. |
| <b>switchport port-security mac-address</b>       | Sets the static secure address.                                |
| <b>switchport port-security aging</b>             | Sets the aging time for secure address.                        |

**Platform** N/A

#### Description

## 9.4 switchport port-security binding-filter logging

Use this command to enable binding filter logging.

Use the **no** form of these commands to restore the default setting.

**switchport port-security binding-filter logging [ rate-limit *rate* ]**

**no switchport port-security binding-filter logging**

#### Parameter Description

| Parameter                     | Description                                                                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rate-limit <i>rate</i></b> | Indicates the printing rate of binding filter logging. The default rate is 10logs/minute. The configurable range is from 1 to 120 logs per minute. |

**Defaults** By default, binding filter logging is disabled.

**Command Mode** Global configuration mode

- Usage Guide**
1. If you run the **switchport port-security binding-filter logging** command without configuring the *rate* parameter, binding filter logging is enabled and the default printing rate, 10logs/minute, is adopted.
  2. After binding filter logging is enabled, for packets that do not comply with IP/IP-MAC binding, warnings are printed.
  3. After binding filter logging is enabled, if the printing rate exceeds the configured rate, the number of

suppressed packets is displayed.

**Configuration** The following example enables binding filter logging.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# switchport port-security binding-filter logging
Ruijie(config)# end
```

## 9.5 switchport port-security interface binding

Use these commands to configure secure address binding manually in the privileged EXEC mode through performing the source IP address plus source MAC address binding or only the source IP address binding. With this binding configured, only the packets match the binding secure address could enter the switch, others will be discarded.

Use the **no** form of these commands to remove the binding addresses.

**switchport port-security interface** *interface-id* **binding** [ *mac-address* **vlan** *vlan\_id* ] { *ipv4-address* | *ipv6-address* }

**switchport port-security interface** *interface-id* **binding** { *ipv4-address* | *ipv6-address* }

**no switchport port-security interface** *interface-id* **binding** [ *mac-address* **vlan** *vlan\_id* ] { *ipv4-address* | *ipv6-address* }

**no switchport port-security interface** *interface-id* **binding** { *ipv4-address* | *ipv6-address* }

**Parameter  
Description**

| Parameter           | Description                               |
|---------------------|-------------------------------------------|
| <i>interface-id</i> | Binds interface ID.                       |
| <i>mac-address</i>  | Binds source MAC address.                 |
| <i>vlan_id</i>      | VLAN ID of the binding source MAC address |
| <i>ipv4-address</i> | Binds IPv4 address.                       |
| <i>ipv6-address</i> | Binds IPv6 address .                      |

**Defaults** N/A

**Command  
Mode** Global configuration mode

**Usage Guide**

1. For packets complying with IP/IP-MAC binding, they can be forwarded only if MAC addresses are secure addresses.
2. For dynamic secure addresses, packets cannot be forwarded before bound even if their addresses

comply with the binding list.

**Configuration** The following example binds the IP address 192.168.1.100 on the interface g 0/10.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# switchport port-security binding interface g0/10 binding
192.168.1.100
Ruijie(config)# end
```

The following example binds the IP address 192.168.1.100 and MAC address 00d0.f800.5555 with VLAN ID 1 on the interface g 0/10.

```
Ruijie# configure terminal
Ruijie(config)# switchport port-security binding interface g0/10 binding
00d0.f800.5555 vlan 1 192.168.1.100
Ruijie(config)# end
```

| <b>switchport port-security binding</b>     | Configures the secure address binding in interface configuration mode. |
| <b>switchport port-security mac-address</b> | Sets the static secure address.                                        |
| <b>switchport port-security aging</b>       | Sets the aging time for secure address.                                |

**Platform** N/A

**Description**

## 9.6 switchport port-security mac-address

Use this command to configure the static secure address.

Use the **no** form of this command to remove the configuration.

**switchport port-security mac-address *mac-address* [ vlan *vlan-id* ]**

**no switchport port-security mac-address *mac-address* [ vlan *vlan-id* ]**

**Parameter  
Description**

| Parameter          | Description                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>mac-address</i> | Static secure MAC address                                                                                                                                                                      |
| <i>vlan-id</i>     | VLAN ID of the MAC address<br><br> The configuration of <i>vlan-id</i> is only supported on the TRUNK port. |

**Defaults** N/A

**Command** Interface configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration Examples** The following example sets the static secure address and VLAN ID of TRUNK port 10 to 00d0.f800.5555 and 2 respectively.

```
Ruijie# configure terminal
Ruijie(config)#interface gigabitethernet 0/10
Ruijie(config-if)# switchport port-security mac-address 00d0.f800.5555 vlan
2
Ruijie(config-if)# end
```

| <b>switchport port-security aging</b>                 | Sets the aging time for the secure address.             |

**Platform** N/A  
**Description**

## 9.7 switchport port-security interface mac-address

Use this command to configure the static secure address.

Use the **no** form of this command to remove the configuration.

**switchport port-security interface** *interface-id* **mac-address** *mac-address* [ **vlan** *vlan-id* ]

**no switchport port-security interface** *interface-id* **mac-address** *mac-address* [ **vlan** *vlan-id* ]

**Parameter Description**

| Parameter           | Description                                                                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>interface-id</i> | Interface ID                                                                                                                                                                               |
| <i>mac-address</i>  | Static secure address                                                                                                                                                                      |
| <i>vlan-id</i>      | VLAN ID of the MAC address<br> The configuration of <i>vlan-id</i> is only supported on the TRUNK port. |

**Defaults** N/A

**Command** Glocal configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration Examples** The following example sets the static secure address and VLAN ID of TRUNK port 10 to 00d0.f800.5555 and 2 respectively.

```
Ruijie# configure terminal
Ruijie(config)# switchport port-security interface g0/10 mac-address
00d0.f800.5555 vlan 2
Ruijie(config)# end
```

**Related Commands**

| Command                                     | Description                                                     |
|---------------------------------------------|-----------------------------------------------------------------|
| <b>show port-security</b>                   | Displays port security settings.                                |
| <b>switchport port-security</b>             | Enables the port-security.                                      |
| <b>switchport port-security binding</b>     | Configures the secure address binding.                          |
| <b>switchport port-security mac-address</b> | Sets the static secure address in interface configuration mode. |
| <b>switchport port-security aging</b>       | Sets the aging time for the secure address.                     |

**Platform** N/A  
**Description**

## 9.8 switchport port-security maximum

Use this command to set the maximum number of port secure addresses.

Use the **no** form of this command to restore the default setting.

**switchport port-security maximum** *value*

**no switchport port-security maximum**

**Parameter Description**

| Parameter    | Description                                                       |
|--------------|-------------------------------------------------------------------|
| <i>value</i> | Maximum number of the secure address, in the range from 1 to 128. |

**Defaults** The default is 128.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** The number of the secure address contains the sum of static secure address and dynamically learnt secure address, 128 by default.  
 If the number of the secure address you set is less than current number, it will prompt this setting failure.

**Configuration** The following example sets the maximum number of the secure address to 2 for interface g 0/10.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)#interface gigabitethernet 0/10
Ruijie(config-if)# switchport port-security maximum 2
Ruijie(config-if)# end
```

**Related  
Commands**

|---------------------------------------------|---------------------------------------------------------------------|
| <b>show port-security</b>                   | Displays port security settings.                                    |
| <b>switchport port-security</b>             | Enables the port-security.                                          |
| <b>switchport port-security binding</b>     | Configures the secure address binding.                              |
| <b>Switchport port-security mac-address</b> | Sets the static secure address in the interface configuration mode. |
| <b>switchport port-security aging</b>       | Sets the aging time for the port secure address.                    |

**Platform** N/A

**Description**

## 9.9 switchport port-security mac-address sticky

Use this command to configure the Sticky MAC secure address.

Use the **no** form of this command to restore the default setting.

**switchport port-security mac-address sticky** *mac-address* [ **vlan** *vlan-id* ]

**no switchport port-security mac-address sticky** *mac-address* [ **vlan** *vlan-id* ]

Use the command without parameters to enable the Sticky MAC address learning.

Use the **no** form of this command to disable the Sticky MAC address learning.

**switchport port-security mac-address sticky**

**no switchport port-security mac-address sticky**

**Parameter  
Description**

| Parameter          | Description                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>mac-address</i> | Static secure address                                                                                                                                        |
| <i>vlan-id</i>     | Vlan ID of the MAC address                                                                                                                                   |
|                    |  The configuration of <i>vlan-id</i> is only supported on the TRUNK port. |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Sticky MAC addresses, either static or dynamic, are special addresses free from aging.

**Configuration** The following example sets the MAC address and VLAN ID of TRUNK port 10 to 00d0.f800.5555 to 2 respectively.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)#interface gigabitethernet 0/10
Ruijie(config-if)# switchport port-security mac-address 00d0.f800.5555 vlan
2
Ruijie(config-if)# end
```

The following example enables the Sticky MAC address learning on interface g0/10.

```
Ruijie# configure terminal
Ruijie(config)#interface gigabitethernet 0/10
Ruijie(config-if)# switchport port-security sticky mac-address
Ruijie(config-if)# end
```

| <b>show port-security</b>                             | Displays port security settings.                                |
| <b>switchport port-security</b>                       | Enables the port-security.                                      |
| <b>switchport port-security binding</b>               | Configures the secure address binding.                          |
| <b>switchport port-security mac-address interface</b> | Sets the static secure address in privileged EXEC mode.         |
| <b>switchport port-security mac-address</b>           | Sets the static secure address in interface configuration mode. |
| <b>switchport port-security aging</b>                 | Sets the aging time for the secure address.                     |

**Platform** N/A

**Description**

## 9.10 show port-security

Use this command to display the port security configuration and the secure address.

**show port-security** [ **address** [ **interface** *interface-id* ] | **binding** [ **interface** *interface-id* ] | **interface** *interface-id* | **all** ]

**Parameter  
Description**

| Parameter                            | Description                                                                               |
|--------------------------------------|-------------------------------------------------------------------------------------------|
| <b>address</b>                       | Displays all secure addresses, or the secure address of the specified port.               |
| <b>binding</b>                       | Displays all port security bindings, or the port security bindings of the specified port. |
| <b>interface</b> <i>interface-id</i> | Displays the port security configuration of the specified port.                           |
| <b>all</b>                           | Displays all valid secure addresses and valid port security bindings.                     |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** To display all port security configuration and violation management, execute the command without any parameter. To display the security configuration, the secure address, or the port security binding of the specified interface, execute the command with the corresponding parameter.

**Configuration Examples** The following example displays the port security statistics.

```
Ruijie#show port-security
NO. SecurePort MaxSecureAddr CurrentAddr CurrentIpBind CurrentIpMacBind
SecurityAction
          (Count)      (Count)      (Count)      (Count)
-----
-----
1   Gi0/1   128          2          2          1          protect
-----
-----
Total secure addresses in System : 2
Total secure bindings in System : 3
```

| Field                            | Description                                                |
|----------------------------------|------------------------------------------------------------|
| NO.                              | Serial number.                                             |
| Secure Port                      | Port name                                                  |
| MaxSecureAddr(count)             | The maximum number of secure addresses on the port.        |
| CurrentAddr(count)               | The current number of secure addresses on the port.        |
| CurrentIpBind (count)            | The current number of IP addresses bindings on the port.   |
| CurrentIpMacBind (count)         | The current number of IP-MAC address bindings on the port. |
| Security Action                  | Violation management.                                      |
| Total secure addresses in System | The total number of secure addresses on the device.        |
| Total secure bindings in System  | The total number of port security bindings on the device,  |

The following example displays the port security configuration on interface GigabitEthernet 0/1.

```
Ruijie#show port-security interface gigabitEthernet 0/1
Interface           : GigabitEthernet 0/1
Port status         : down
Port Security       : enabled
```

```
SecureStatic address aging : disabled
Sticky dynamic address    : disabled
Violation mode            : protect
Maximum MAC Addresses     : 128
Total MAC Addresses       : 2
Configured MAC Addresses  : 2
Dynamic MAC Addresses     : 0
Sticky MAC Addresses      : 0
Total security binding    : 3
IPv4-ONLY Binding Addresses : 1
IPv6-ONLY Binding Addresses : 1
IPv4-MAC Binding Addresses : 1
IPv6-MAC Binding Addresses : 0
Aging time(min)          : 0
```

| Field                       | Description                                                                            |
|-----------------------------|----------------------------------------------------------------------------------------|

## 10 Storm Control Commands

### 10.1 show storm-control

Use this command to display storm suppression information.

**show storm-control** [ *interface-type interface-number* ]

| Parameter Description | Parameter                                        | Description             |
|-----------------------|--------------------------------------------------|-------------------------|
|                       | <i>interface-type</i><br><i>interface-number</i> | Specifies an interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example displays storm control configuration on FastEthernet 0/1.

```
Ruijie# show storm-control fastEthernet 0/1
Interface          Broadcast Control Multicast Control Unicast Control
Action
-----
FastEthernet 0/1  1%          50%          1%          none
```

| Related Commands | Command              | Description                |
|------------------|----------------------|----------------------------|
|                  | <b>storm-control</b> | Enables storm suppression. |

**Platform** N/A

**Description**

### 10.2 storm-control

Use this command to enable the storm suppression for unknown unicast packets.

Use the **no** or **default** form of this command to restore the default setting.

**storm-control unicast** [ { *level percent* | *pps packets* | *rate-bps* } ]

**no storm-control unicast**

**default storm-control unicast**

Use this command to enable the storm suppression for multicast packets.  
 Use the **no** or **default** form of this command to restore the default setting.  
**storm-control multicast** [ { **level percent** | **pps packets** | **rate-bps** } ]  
**no storm-control multicast**  
**default storm-control multicast**

Use this command to enable the storm suppression for broadcast packets.  
 Use the **no** or **default** form of this command to restore the default setting.  
**storm-control broadcast** [ { **level percent** | **pps packets** | **rate-bps** } ]  
**no storm-control broadcast**  
**default storm-control broadcast**

| Parameter Description | Parameter            | Description                                               |
|-----------------------|----------------------|-----------------------------------------------------------|
|                       | <b>level percent</b> | Sets the bandwidth percentage, for example, 20 means 20%. |
|                       | <b>pps packets</b>   | Sets the pps, which means packets per second.             |
|                       | <b>rate-bps</b>      | Rate allowed                                              |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Too many broadcast, multicast or unicast packets received on a port may cause storm and thus slow network and increase timeout. Protocol stack implementation errors or wrong network configuration may also lead to such storms.  
 A device can implement the storm suppression to a broadcast, a multicast, or a unicast storm respectively. When excessive broadcast, multicast or unknown unicast packets are received, the switch temporarily prohibits forwarding of relevant types of packets till data streams are recovered to the normal state (then packets will be forwarded normally).

**Configuration Examples** The following example enables the multicast storm suppression on FastEthernet 0/1 and sets the allowed rate to 4M.

```
Ruijie(config)# int fastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)# storm-control multicast 4096
```

# 11 SSH Commands

## 11.1 crypto key generate

Use this command to generate a public key to the SSH server.

**crypto key generate { rsa | dsa }**

| Parameter   | Parameter  | Description           |
|-------------|------------|-----------------------|
| Description | <b>rsa</b> | Generates an RSA key. |
|             | <b>dsa</b> | Generates a DSA key.  |

**Defaults** By default, the SSH server does not generate a public key.

**Command** Global configuration mode

**Mode**

**Usage Guide** When you need to enable the SSH SERVER service, use this command to generate a public key on the SSH server and enable the SSH SERVER service by command **enable service ssh-server** at the same time. SSH 1 uses the RSA key; SSH 2 uses the RSA or DSA key. Therefore, if a RSA key has been generated, both SSH1 and SSH2 can use it. If only a DSA key is generated, only SSH2 can use it.

 Only DSA/RSA authentication is available for one connection. Also, the key algorithm may differ in different client. Thus, it is recommended to generate both RSA and DSA keys so as to ensure connection with the portal server.

 RSA has a minimum modulus of 512 bits and a maximum modulus of 2,048 bits; DSA has a minimum modulus of 360 bits and a maximum modulus of 2,048 bits. For some clients like SCP clients, a 768-bit or more key is required. Thus, it is recommended to generate the key of 768 bits or more.

 A key can be deleted by using the **no crypto key generate** command. The **no crypto key zeroize** command is not available.

**Configuration** The following example generates an RSA key to the SSH server.

**Examples**

```
Ruijie# configure terminal
Ruijie(con fig)# crypto key generate rsa
```

| Related Commands | Command                                 | Description                                                    |
|------------------|-----------------------------------------|----------------------------------------------------------------|
|                  | <b>show ip ssh</b>                      | Displays the current status of the SSH server.                 |
|                  | <b>crypto key zeroize { rsa   dsa }</b> | Deletes DSA and RSA keys and disables the SSH server function. |

**Platform** N/A  
**Description**

## 11.2 crypto key zeroize

Use this command to delete a public key to the SSH server.

**crypto key zeroize { rsa | dsa }**

|                    | Parameter  | Description          |
|--------------------|------------|----------------------|
| <b>Parameter</b>   |            |                      |
| <b>Description</b> | <b>rsa</b> | Deletes the RSA key. |
|                    | <b>dsa</b> | Deletes the DSA key. |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command deletes the public key to the SSH server. After the key is deleted, the SSH server state becomes DISABLE. If you want to disable the SSH server, run the **no enable service ssh-server** command.

**Configuration Examples** The following example deletes a RSA key to the SSH server.

```
Ruijie# configure terminal
Ruijie(config)# crypto key zeroize rsa
```

|                         | Command                                  | Description                                    |
|-------------------------|------------------------------------------|------------------------------------------------|
| <b>Related Commands</b> | <b>show ip ssh</b>                       | Displays the current status of the SSH server. |
|                         | <b>crypto key generate { rsa   dsa }</b> | Generates DSA and RSA keys.                    |

**Platform** N/A  
**Description**

## 11.3 disconnect ssh

Use this command to disconnect the established SSH connection.

**disconnect ssh [ vty ] session-id**

|                    | Parameter         | Description                                                     |
|--------------------|-------------------|-----------------------------------------------------------------|
| <b>Parameter</b>   |                   |                                                                 |
| <b>Description</b> | <b>vtty</b>       | Established VTY connection                                      |
|                    | <i>session-id</i> | ID of the established SSH connection, in the range from 0 to 35 |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** You can disconnect a SSH connection by entering the ID of the SSH connection or disconnect a SSH connection by entering the specified VTY connection ID. Only connections of the SSH type can be disconnected.

**Configuration Examples** The following example disconnects the established SSH connection by specifying the SSH session ID.

```
Ruijie# disconnect ssh 1
```

The following example disconnects the established SSH connection by specifying the VTY session ID.

```
Ruijie# disconnect ssh vty 1
```

**Related Commands**

| Command                                  | Description                                                    |
|------------------------------------------|----------------------------------------------------------------|
| <b>show ssh</b>                          | Displays the information about the established SSH connection. |
| <b>clear line vty <i>line_number</i></b> | Disconnects the current VTY connection.                        |

**Platform Description** N/A

## 11.4 ip scp server enable

Use this command to enable the SCP server function on a network device.

Use the **no** form of this command to restore the default setting.

**ip scp server enable**

**no ip scp server enable**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** Secure Copy (SCP) enables an authenticated user to transfer files to/from a remote device in an encrypted way, with high security and guarantee.

**Configuration Examples** The following example enables the SCP server function.

```
Ruijie# configure terminal
Ruijie(config)# ip scp server enable
```

| Related Commands | Command            | Description                                    |
|------------------|--------------------|------------------------------------------------|
|                  | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform** N/A

**Description**

## 11.5 ip scp server topdir

Use this command to set the path for uploading/downloading files to/from the SCP server.

Use the **no** form of this command to restore the default settings.

**ip scp server topdir** {**flash:/path** | **flash2:/path** | **usb0:/path** | **usb1:/path** | **sd0:/path** | **sata0:/path** | **tmp:/path**}

**no ip scp server topdir**

| Parameter Description | Parameter     | Description                                                                                                                                                        |
|-----------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>flash</b>  | Selects the file transfer path from the extended flash memory. The file transfer path is <b>flash:/</b> by default.                                                |
|                       | <b>flash2</b> | Selects the file transfer path from Extended Flash Memory 2. This option is supported only when the device has the data2 partition.                                |
|                       | <b>usb0</b>   | Selects the file transfer path from USB Disk 0. This option is supported only when the device has one USB interface and is connected with an extended USB device.  |
|                       | <b>usb1</b>   | Selects the file transfer path from USB Disk 1. This option is supported only when the device has two USB interfaces and is connected with extended USB devices.   |
|                       | <b>sd0</b>    | Selects the file transfer path from the SD card. This option is supported only when the device has an SD card interface and is connected with an extended SD card. |
|                       | <b>sata0</b>  | Selects the file transfer path from the hard disk. This option is supported only when the device has the SATA partition.                                           |
|                       | <b>tmp</b>    | Sets the file transfer path to <b>tmp/vsd/</b> .                                                                                                                   |

**Defaults** The file transfer path is **flash:/** by default.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** This command is used to change the file transfer path for uploading and downloading files.

**Configuration Examples** The following example changes the file transfer path to **tmp/vsd**.

```
Ruijie# configure terminal
```

```
Ruijie(config)# ip scp server topdir tmp:/
```

## 11.6 ip ssh access-class

Use this command to set the ACL filtering of the SSH server.

**ip ssh access-class** { *access-list-number* | *access-list-name* }

Use the **no** form of this command to delete the ACL filtering of the SSH server.

**no ip ssh access-class**

| Parameter   | Parameter                 | Description                                                                                                                                                                           |
|-------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>access-list-number</i> | The ACL number and the number range is configurable. The standard ACL number ranges are 1 to 99 and 1,300 to 1,999. The extended ACL number ranges are 100 to 199 and 2,000 to 2,699. |
|             | <i>access-list-name</i>   | An ACL name.                                                                                                                                                                          |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** Run this command to perform ACL filtering for all connections to the SSH server. In line mode, ACL filtering is performed only for specific lines. However, ACL filtering rules of the SSH are effective to all SSH connections.

**Configuration Examples** The following example performs the ACL filtering named testv4 for all connections to the SSH server.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# ip ssh access-class testv4
```

**Platform** N/A

**Description**

## 11.7 ip ssh authentication-retries

Use this command to set the authentication retry times of the SSH server.

Use the **no** form of this command to restore the default setting.

**ip ssh authentication-retries** *retry times*

**no ip ssh authentication-retries**

| Parameter   | Parameter          | Description                                     |
|-------------|--------------------|-------------------------------------------------|
| Description | <i>retry times</i> | Authentication retry times, ranging from 0 to 5 |

**Defaults** The default is 3.

**Command** Global configuration mode  
**Mode**

**Usage Guide** User authentication is considered failed if authentication is not successful when the configured authentication retry times on the SSH server is exceeded. Use the **show ip ssh** command to display the configuration of the SSH server

**Configuration** The following example sets the authentication retry times to 2.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh authentication-retries 2
```

| Related Commands | Command            | Description                                    |
|------------------|--------------------|------------------------------------------------|
|                  | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform** N/A  
**Description**

## 11.8 ip ssh cipher-mode

Use this command to set the SSH server encryption mode.

Use the **no** form of this command to restore the default setting.

**ip ssh cipher-mode { cbc | ctr | others }**

**no ip ssh cipher-mode**

| Parameter Description | Parameter     | Description                                                                                                                                   |
|-----------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>cbc</b>    | Encryption mode: CBC (Cipher Block Chaining)<br>Encryption algorithm: DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blow fish-CBC |
|                       | <b>ctr</b>    | Encryption mode: CTR (Counter)<br>Encryption algorithm: AES128-CTR, AES192-CTR, AES256-CTR                                                    |
|                       | <b>others</b> | Encryption mode: Others<br>Encryption algorithm: RC4                                                                                          |

**Defaults** All encryption modes are supported by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** This command is used to set the SSH server encryption mode.  
 For Ruijie Networks, the SSHv1 server supports DES-CBC, 3DES-CBC, and Blowfish-CBC; the SSHv2 server supports AES128-CTR, AES192-CTR, AES256-CTR, DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blowfish-CBC, and RC4. All these algorithms can be grouped into CBC, CTR and Other as shown above.  
 With the advancement of cryptography study, CBC and Others encryption modes are proved to easily

decipher. It is recommended to enable the CTR mode to raise assurance for organizations and enterprises demanding high security.

**Configuration** The following example enables CTR encryption mode.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh cipher-mode ctr
```

**Platform** N/A

**Description**

## 11.9 ip ssh hmac-algorithm

Use this command to set the algorithm for message authentication.

Use the **no** form of this command to restore the default setting.

**ip ssh hmac-algorithm { md5 | md5-96 | sha1 | sha1-96 }**

**no ip ssh hmac-algorithm**

**Parameter**

**Description**

| Parameter | Description       |
|-----------|-------------------|
| md5       | MD5 algorithm     |
| md5-96    | MD5-96 algorithm  |
| sha1      | SHA1 algorithm    |
| sha1-96   | SHA1-96 algorithm |

**Defaults**

SSHv1: all the algorithms are not supported.

SSHv2: all the algorithms are supported.

**Command**

Global configuration mode

**Mode**

**Usage Guide**

Ruijie SSHv1 servers do not support algorithms for message authentication.

For Ruijie Networks, the SSHv1 server does not support message authentication algorithms; the SSHv2 server supports MD5, MD5-96, SHA1, and SHA1-96 algorithms. Set the algorithm on your demand.

**Configuration**

The following example sets the algorithm for message authentication to SHA1.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh hmac-algorithm sha1
```

**Platform** N/A

**Description**

## 11.10 ip ssh key-exchange

Use this command to configure support for DH key exchange method on the SSH server

Use the **no** form of this command to restore the default setting.

```
ip ssh key-exchange { dh_group_exchange_sha1 | dh_group14_sha1 | dh_group1_sha1 }
no ip ssh key-exchange
```

| Parameter   | Parameter                     | Description                                                                                                                     |
|-------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Description | <b>dh_group_exchange_sha1</b> | Indicates configuration of diffie-hellman-group-exchange-sha1 for keyexchange. The key has 2,048 bytes, which cannot be edited. |
|             | <b>dh_group14_sha1</b>        | Indicates configuration of diffie-hellman-group14-sha1 for keyexchange. The key has 2,048 bytes.                                |
|             | <b>dh_group1_sha1</b>         | Indicates configuration of diffie-hellman-group1-sha1 for keyexchange. The key has 1,024 bytes.                                 |

**Defaults** By default, the SSHv1 server does not support DH key exchange method, while the SSHv2 server supports diffie-hellman-group-exchange-sha1 and diffie-hellman-group14-sha1 for key exchange.

**Command** Global configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example configures the support for diffie-hellman-group14-sha1.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh key-exchange dh_group14_sha1
```

| Related  | Command            | Description                                    |
|----------|--------------------|------------------------------------------------|

**Platform** N/A

**Description**

## 11.11 ip ssh peer

Use this command to associate the public key file and the user name on the client. During client login authentication, you can specify a public key file based on the user name.

Use the **no** form of this command to restore the default setting.

```
ip ssh peer username public-key { rsa | dsa } filename
no ip ssh peer username public-key { rsa | dsa } filename
```

| Parameter   | Parameter       | Description                 |
|-------------|-----------------|-----------------------------|
| Description | <i>username</i> | User name                   |
|             | <i>filename</i> | Name of a public key file   |
|             | <b>rsa</b>      | The public key is a RSA key |
|             | <b>dsa</b>      | The public key is a DSA key |

**Defaults** N/A

**Command** Global configuration mode  
**Mode**

**Usage Guide** N/A

**Configuration** The following example sets RSA and DSA key files associated with user **test**.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh peer test public-key rsa flash:rsa.pub
Ruijie(config)# ip ssh peer test public-key dsa flash:dsa.pub
```

| Related  | Command            | Description                                    |
|----------|--------------------|------------------------------------------------|
| Commands | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform** N/A  
**Description**

## 11.12 ip ssh port

Use this command to set a monitoring port ID for the SSH server.

**ip ssh port** *port*

Use either of the following commands to restore the monitoring port ID of the SSH server to the default value.

**no ip ssh port**

**ip ssh port 22**

| Parameter   | Parameter   | Description                                                                |
|-------------|-------------|----------------------------------------------------------------------------|
| Description | <i>port</i> | Monitoring port ID of the SSH server. The value ranges from 1025 to 65535. |

**Defaults** N/A

**Command** Global configuration mode  
**Mode**

**Default Level** 14

**Usage Guide** N/A

**Configuration** The following example sets the monitoring port ID of the SSH server to 10000.

**n Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh port 10000
```

**Verification** Run the **show ip ssh** command to display the configured monitoring port ID of the SSH server.

**Prompts**

1. If the required port ID is the same as the current value, a prompt is displayed, indicating that the current port ID is the required value.

```
Ruijie(config)# ip ssh port 22
% SSH tcp-port has been 22
```

2. If a port in the monitoring state is configured as the monitoring port of the SSH server, a prompt is displayed, indicating that the port is already in the monitoring state and you are required to set another port ID, and the SSH server still uses the previous port ID.

```
Ruijie(config)# ip ssh port 10000
% SSH open tcp-port(10000) failed, please use another tcp-port, otherwise the system will use the old tcp-port(22)!
```

3. If a monitoring error occurs after a monitoring port ID is configured for the SSH server, a port ID configuration failure prompt is displayed.

```
Ruijie(config)# ip ssh port 10000
% SSH change to tcp-port(10000) fail!
```

4. If a port ID is configured successfully, a port ID configuration success prompt is displayed.

```
Ruijie(config)# ip ssh port 10000
% SSH change to tcp-port(10000) success!
```

## 11.13 ip ssh time-out

Use this command to set the authentication timeout for the SSH server.

Use the **no** form of this command to restore the default setting.

**ip ssh time-out** *time*

**no ip ssh time-out**

| Parameter   | Parameter   | Description                                                               |
|-------------|-------------|---------------------------------------------------------------------------|
| Description | <i>time</i> | Authentication timeout, in the range from 1 to 120 in the unit of seconds |

**Defaults** The default is 120 seconds.

**Command** Global configuration mode

**Mode**

**Usage Guide** The authentication is considered timeout and failed if the authentication is not successful within 120 seconds starting from receiving a connection request. Use the **show ip ssh** command to display the configuration of the SSH server.

**Configuration** The following example sets the timeout value to 100 seconds.

**Examples** Ruijie# configure terminal

```
Ruijie(config)# ip ssh time-out 100
```

| Related  | Command            | Description                                    |
|----------|--------------------|------------------------------------------------|
| Commands | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform** N/A

**Description**

## 11.14 ip ssh version

Use this command to set the version of the SSH server.

Use the **no** form of this command to restore the default setting.

**ip ssh version { 1 / 2 }**

**no ip ssh version**

| Parameter   | Parameter | Description                                  |
|-------------|-----------|----------------------------------------------|
| Description | <b>1</b>  | Supports the SSH1 client connection request. |
|             | <b>2</b>  | Supports the SSH2 client connection request. |

**Defaults** SSH1 and SSH2 are compatible by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This command is used to configure the SSH connection protocol version supported by SSH server. By default, the SSH server supports SSH1 and SSH2. If Version 1 or 2 is set, only the SSH client of this version can connect to the SSH server. Use the **show ip ssh** command to display the current status of SSH server.

**Configuration** The following example sets the version of the SSH server.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip ssh version 2
```

| Related  | Command            | Description                                    |
|----------|--------------------|------------------------------------------------|
| Commands | <b>show ip ssh</b> | Displays the current status of the SSH server. |

**Platform** N/A

**Description**

## 11.15 ipv6 ssh access-class

Use this command to set the IPv6 ACL filtering of the SSH server.

**ipv6 ssh access-class accessv6-list-name**

Use the **no** form of this command to delete the IPv6 ACL filtering of the SSH server.

**no ipv6 ssh access-class**

| <b>Parameter Description</b>  | <table border="1"> <thead> <tr> <th>Parameter</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td><i>accessv6-list-name</i></td> <td>An IPv6 ACL name.</td> </tr> </tbody> </table>                                                       | Parameter | Description | <i>accessv6-list-name</i> | An IPv6 ACL name. |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|-------------|---------------------------|-------------------|
| Parameter                     | Description                                                                                                                                                                                                                                     |           |             |                           |                   |
| <i>accessv6-list-name</i>     | An IPv6 ACL name.                                                                                                                                                                                                                               |           |             |                           |                   |
| <b>Defaults</b>               | N/A                                                                                                                                                                                                                                             |           |             |                           |                   |
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                                                                                                       |           |             |                           |                   |
| <b>Usage Guide</b>            | Run this command to perform IPv6 ACL filtering for all connections to the SSH server. In line mode, IPv6 ACL filtering is performed only for specific lines. However, IPv6 ACL filtering rules of the SSH are effective to all SSH connections. |           |             |                           |                   |
| <b>Configuration Examples</b> | <p>The following example performs the IPv6 ACL filtering named testv6 for all connections to the SSH server.</p> <pre>Ruijie# configure terminal Ruijie(config)# ipv6 ssh access-class testv6</pre>                                             |           |             |                           |                   |
| <b>Platform Description</b>   | N/A                                                                                                                                                                                                                                             |           |             |                           |                   |

## 11.16 show crypto key mypubkey

Use this command to display the information about the public key part of the public key to the SSH server.

**show crypto key mypubkey { rsa | dsa }**

| <b>Parameter Description</b> | <table border="1"> <thead> <tr> <th>Parameter</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td><b>rsa</b></td> <td>Displays the RSA key.</td> </tr> <tr> <td><b>dsa</b></td> <td>Displays the DSA key.</td> </tr> </tbody> </table> | Parameter | Description | <b>rsa</b> | Displays the RSA key. | <b>dsa</b> | Displays the DSA key. |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|-------------|------------|-----------------------|------------|-----------------------|
| Parameter                    | Description                                                                                                                                                                                                                                  |           |             |            |                       |            |                       |
| <b>rsa</b>                   | Displays the RSA key.                                                                                                                                                                                                                        |           |             |            |                       |            |                       |
| <b>dsa</b>                   | Displays the DSA key.                                                                                                                                                                                                                        |           |             |            |                       |            |                       |
| <b>Defaults</b>              | N/A                                                                                                                                                                                                                                          |           |             |            |                       |            |                       |
| <b>Command Mode</b>          | Privileged EXEC mode/Global configuration mode                                                                                                                                                                                               |           |             |            |                       |            |                       |
| <b>Usage Guide</b>           | This command is used to show the information about the public key part of the generated public key on the SSH server, including key generation time, key name, contents in the public key part, etc.                                         |           |             |            |                       |            |                       |
| <b>Configuration</b>         | The following example displays the information about the public key part of the public key to the SSH                                                                                                                                        |           |             |            |                       |            |                       |

**Examples**

| Related Commands | Command                                  | Description                 |
|------------------|------------------------------------------|-----------------------------|
|                  | <b>crypto key generate { rsa   dsa }</b> | Generates DSA and RSA keys. |

**Platform** N/A  
**Description**

### 11.17 show ip ssh

Use this command to display the information of the SSH server.

**show ip ssh**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode

**Usage Guide** This command is used to display the information of the SSH server, including version, enablement state, port ID, encryption, message authentication algorithm, authentication timeout, and authentication retry times.

Note: If no key is generated for the SSH server, the SSH version is still unavailable even if this SSH version has been configured.

**Configuration** The following example displays the information of the SSH server.

**Examples**

```
Ruijie(config)#show ip ssh
SSH Disable - version 1.99
please generate rsa and dsa key to enable SSH
SSH Port:                22
SSH Cipher Mode:         cbc,ctr,others
SSH HMAC Algorithm:      md5-96,md5,sha1-96,sha1
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:          disabled

// 显示 SSH Server 功能和 SCP 功能均已打开的配置信息
Ruijie(config)#show ip ssh
SSH Enable - version 1.99
SSH Port:                22
SSH Cipher Mode:         cbc,ctr,others
SSH HMAC Algorithm:      md5-96,md5,sha1-96,sha1
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:          enabled
```

|--------------------------------------|---------------------------------------------------------|
| <b>ip ssh version {1   2}</b>        | Configures the version for the SSH server.              |
| <b>ip ssh time-out time</b>          | Sets the authentication timeout for the SSH server.     |
| <b>ip ssh authentication-retries</b> | Sets the authentication retry times for the SSH server. |

**Platform** N/A

**Description**

## 11.18 show ssh

Use this command to display the information about the established SSH connection.

**show ssh**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode/Global configuration mode

**Usage Guide** This command is used to display the information about the established SSH connection, including VTY number of connection, SSH version, encryption algorithm, message authentication algorithm, connection status, and user name.

**Configuration** The following example displays the information about the established SSH connection:

**Examples**

```
Ruijie#show ssh
Connection Version Encryption      Hmac      Compress  State
Username
      0      1.5 blowfish                      zlib      Session started test
      1      2.0 aes256-cbc    hmac-sha1  zlib      Session started test
```

## Field Description

| Field      | Description                      |
|------------|----------------------------------|
| Connection | VTY number                       |
| Version    | SSH version                      |
| Encryption | Encryption algorithm             |
| Hmac       | Message authentication algorithm |
| Compress   | Compress algorithm               |

## 12 URPF Commands

### 12.1 clear ip urpf

Use this command to clear IPv4 URPF packet drop statistics.

**clear ip urpf** [ **interface** *interface-name* ]

**Parameter Description**

| Parameter                              | Description                                   |
|----------------------------------------|-----------------------------------------------|
| <b>interface</b> <i>interface-name</i> | Clears statistics on the specified interface. |

**Defaults**

N/A

**Command Mode**

Privileged EXEC mode

**Usage Guide** If no interface is specified, IPv4 URPF packet drop statistics on all interfaces are cleared by default.

**Configuration** The following example clears IPv4 URPF packet drop statistics on port GigabitEthernet 0/1.

**Examples**

```
Ruijie# clear ip urpf interface gigabitEthernet0/1
```

The following example clears IPv4 URPF packet drop statistics on all interfaces.

```
Ruijie# clear ip urpf
```

**Related  
Commands**

| Command     | Description                                     |
|-------------|-------------------------------------------------|
| showip urpf | Displays the URPF configuration and statistics. |

**Platform** N/A

**Description**

## 12.2 ip verify unicast source reachable-via (Interface Configuration Mode)

Use this command to enable the IPv4 URPF feature in the interface configuration mode.

Use the **no** form of this command to restore the default setting.

**ip verify unicast source reachable-via { rx | any } [ allow-default ]**

**no ip verify unicast**

**Parameter  
Description**

| Parameter            | Description                                                                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rx</b>            | URPF check in the strict mode. In the strict mode, the egress port for the forwarding entry in the forwarding list found through the source address for the IP packet shall be matched with the ingress port. |
| <b>any</b>           | URPF check in the loose mode. In the loose mode, the forwarding entry for the source address for the IP packet can be found in the forwarding list.                                                           |
| <b>allow-default</b> | (Optional) Allows using the default route to check URPF.                                                                                                                                                      |

**Defaults** This function is disabled by default.

**Command  
Mode** Interface configuration mode

**Usage Guide** To determine whether the route for the source address is in the forwarding list or not and the packet validity, enable the URPF feature to check the source address for the received IP packets. If no forwarding entry is matched, the packets are illegal.

Enabling URPF feature in the interface configuration mode enables URPF check for the received packets on the interface.

By default, the default route is not used for URPF check. Use the keyword allow-default to enable the

URPF check.

By default, the packets that failed to pass the URPF check are dropped. With ACL (acl-name) configured, the ACL matching continues when the routing fails. The packets will be dropped if the ACL is inexistent or the deny ACE is matched; otherwise, if the permit ACE is matched, the packets will be forwarded.

-  After this command is used, URPF check on IPv4 packets will be enabled.
-  This function is supported only on routed and Layer 3 interfaces, and have the following restrictions:
  - Not support the ACL association;  
Not support to use the IPv6 route with prefix in 65 to 127 bits for the URPF check;
  - After enabling the URPF feature, the range of packets received on the interface will be expanded, that is, the URPF feature is enabled for all packets received on the physical ports.
  - After enabling the URPF feature, it halves the route forwarding capacity.
  - After enabling the URPF feature in the strict mode, the user can match the equivalent route when URPF check is enabled for the packets received on the interface.
-  URPF feature cannot be configured in the global configuration mode and in the interface configuration mode at the same time.
-  URPF feature cannot be configured on range interface.

**Configuration Examples** The following example checks the URPF feature of the received packets in the strict mode on the interface GigabitEthernet 0/1.

```
Ruijie(config)# interface gigabitEthernet0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx
```

**Related Commands**

| Command             | Description                    |
|---------------------|--------------------------------|
| <b>show ip urpf</b> | Displays the URPF information. |

**Platform Description** N/A

## 12.3 ip verify urpf drop-rate compute interval

Use this command to set the URPF drop-rate compute interval.

Use the **no** form of this command to restore the default setting.

**ip verify urpf drop-rate compute interval** *seconds*

**no ip verify urpf drop-rate compute interval**

**Parameter Description**

| Parameter      | Description                                                       |
|----------------|-------------------------------------------------------------------|
| <i>seconds</i> | Sets the URPF drop-rate compute interval, in the range from 30 to |

|  |                             |
|--|-----------------------------|
|  | 300 in the unit of seconds. |
|--|-----------------------------|

**Defaults** The default is 30 seconds.

**Command Mode** Global configuration mode

**Usage Guide** The URPF drop-rate is computed globally for both IPv4 and IPv6 packets on interfaces enabled with URPF.

**Configuration** The following example sets the URPF drop-rate compute interval as 60 seconds.

**Examples** Ruijie(config)# ip verify urpf drop-rate compute interval 60

**Related Commands**

| Command                                          | Description                                     |
|--------------------------------------------------|-------------------------------------------------|
| <b>ip verify urpf drop-rate notify</b>           | Sets the URPF drop-rate information monitoring. |
| <b>ip verify urpf drop-rate notify hold-down</b> | Sets the URPF drop-rate warning interval.       |
| <b>ip verify urpf notification threshold</b>     | Sets the URPF drop-rate threshold.              |

**Platform** N/A

**Description**

## 12.4 ip verify urpf drop-rate notify

Use this command to enable the URPF drop-rate monitoring.

Use the **no** or **default** form of this command to restore the default setting.

**ip verify urpf drop-rate notify**

**no ip verify urpf drop-rate notify**

**default ip verify urpf drop-rate notify**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command is used to enable the URPF drop-rate monitoring, notifying the user of the URPF packet drop information by means of Syslog or Trap for the convenience of the user network monitoring.  
URPF feature cannot be configured on range interface.

**Configuration** The following example enables the URPF drop-rate monitoring on port GigabitEthernet 0/1.

**Examples**

```
Ruijie(config)# interface gigabitEthernet0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify
```

**Related Commands**

| Command                                          | Description                               |
|--------------------------------------------------|-------------------------------------------|
| <b>ip verify urpf drop-rate compute interval</b> | Sets the URPF drop-rate compute interval. |
| <b>ip verify urpf drop-rate notify hold-down</b> | Sets the URPF drop-rate warning interval. |
| <b>ip verify urpf notification threshold</b>     | Sets the URPF drop-rate threshold.        |

**Platform** N/A

**Description**

## 12.5 ip verify urpf drop-rate notify hold-down

Use this command to set the URPF drop-rate notification interval.

Use the **no** form of this command to restore to the default setting.

**ip verify urpf drop-rate notify hold-down** *seconds*

**no ip verify urpf drop-rate notify hold-down**

**Parameter Description**

| Parameter      | Description                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the URPF drop-rate notification interval, in the range from 30 to 300 in the unit of seconds. |

**Defaults** The default is 300 seconds.

**Command** Global configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the URPF drop-rate notification interval as 60 seconds.

**Examples**

```
Ruijie(config)# ip verify urpf drop-rate notify hold-down 60
```

**Related Commands**

| Command                                          | Description                                 |
|--------------------------------------------------|---------------------------------------------|
| <b>ip verify urpf drop-rate compute interval</b> | Sets the URPF drop-rate computing interval. |
| <b>ip verify urpf drop-rate notify</b>           | Sets the URPF drop-rate monitoring.         |
| <b>ip verify urpf notification threshold</b>     | Sets the URPF drop-rate threshold.          |

**Platform** N/A

**Description**

## 12.6 ip verify urpf notification threshold

Use this command to set the URPF drop-rate threshold.

Use the **no** form of this command to restore the default setting.

**ip verify urpf notification threshold** *rate-value*

**no ip verify urpf notification threshold**

| Parameter Description | Parameter                          | Description                                                                                                      |
|-----------------------|------------------------------------|------------------------------------------------------------------------------------------------------------------|
|                       | <b>threshold</b> <i>rate-value</i> | Sets the URPF drop-rate threshold, in the range from 0 to 4,294,967,295 in the unit of packets per second (pps). |

**Defaults** The default is 1,000 pps.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The threshold 0 indicates that once the device detects a dropped packet due to the IPv4 URPF check, the notification is sent.

The user can adjust the drop-rate threshold value according to the actual network performance. URPF feature cannot be configured on range interface.

**Configuration** The following example sets the URPF drop-rate threshold 10pps on the interface GigabitEthernet 0/1.

**Examples**

```
Ruijie(config)# interface gigabitEthernet0/1
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 verify urpf drop-rate notify
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 verify urpf notification
threshold 10
```

|------------------|--------------------------------------------------|-------------------------------------------------|
|                  | <b>ip verify urpf drop-rate compute interval</b> | Sets the URPF drop-rate computing interval.     |
|                  | <b>ip verify urpf drop-rate notify</b>           | Sets the URPF drop-rate information monitoring. |
|                  | <b>ip verify urpf drop-rate notify hold-down</b> | Sets the URPF drop-rate notification interval.  |

**Platform** N/A

**Description**

## 12.7 show ip urpf

Use this command to display the IPv4 URPF configuration and statistics.

**show ip urpf** [ **interface** *interface-name* ]

| Parameter Description | Parameter                              | Description                                                           |
|-----------------------|----------------------------------------|-----------------------------------------------------------------------|
|                       | <b>interface</b> <i>interface-name</i> | Displays the configuration and statistics on the specified interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** The global configuration and statistics of all interfaces are displayed by default.

**Configuration Examples** The following example displays IPv4 URPF configuration and statistics on port GigabitEthernet 0/1.

### Examples

```
Ruijie# show ip urpf interface gigabitEthernet0/21
IP verify source reachable-via RX
IP verify URPF drop-rate notify disabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-rate notification counts in this interface is 0
```

| Field                                                          | Description                                                                                                                      |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| IP verify source reachable-via xx                              | xx in strict mode is displayed as RX and in loose mode as ANY.                                                                   |
| IP verify URPF drop-rate notify xx                             | If drop rate notification is enabled, xx is displayed as enabled. Otherwise, it is displayed as disabled.                        |
| IP verify URPF notification threshold is xxpps                 | The threshold of URPF drop rate, in the range from 0 to 4294967295 in the unit of packets per second (pps). The default is 1000. |
| Number of drop packets in this interface is x                  | The number of drop packets                                                                                                       |
| Number of drop-rate notification counts in this interface is x | The URPF drop-rate notification counts                                                                                           |

The following example displays IPv4 URPF configuration and statistics.

```
Ruijie# show ip urpf
IP verify URPF drop-rate compute interval is 30s
IP verify URPF drop-rate notify hold-down is 300s

Interface GigabitEthernet 0/1
IP verify source reachable-via RX
IP verify URPF drop-rate notify disabled
IP verify URPF notification threshold is 1000pps
```

```
Number of drop packets in this interface is 124
```

```
Number of drop-rate notification counts in this interface is 2
```

| Field                                          | Description                                                                                                                         |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| IP verify URPF drop-rate compute interval is x | Drop-rate computing interval                                                                                                        |
| IP verify URPF drop-rate notify hold-down is x | Drop-rate notification interval                                                                                                     |
| Interface interface-name                       | interface-name is the name of the interface on which URPF is applied. Configuration and statistics on this interface are displayed. |

**Related  
Commands**

**Description**

# 13 CPU Protection Commands

## 13.1 clear cpu-protect-counters

Use this command to clear the CPP statistics.

**clear cpu-protect counters** [ device *device\_num* ]

| Parameter Description | Parameter         | Description                                                                                                                                                                                                                                                                |
|-----------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>device_num</i> | As a single physical device, there is no device parameter; As a VSU, the device parameter indicates the chassis or the box-type device. If no device parameter is specified, that indicates this command takes effect to the master chassis or the master box-type device. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example clears the CPP statistics.

```
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
Total    Total Drop
-----  -
bpdu          6           200             0           0           600         50
Ruijie#clear cpu-protect counters
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
Total    Total Drop
-----  -
bpdu          6           200             0           0           0           0
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 13.2 clear cpu-protect-counters mboard

Use this command to clear the CPP statistics on the supervisor module.

**clear cpu-protect counters mboard**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example clears the CPP statistics on the supervisor module.

**Examples**

```
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
Total      Total Drop
-----
-----
bpdu          6          200          0          0          600          50
Ruijie#clear cpu-protect counters mboard
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
Total      Total Drop
-----
-----
bpdu          6          200          0          0          0          0
```

| Related Commands | Command | Description |

|                  | N/A     | N/A         |

**Platform** N/A

**Description**

## 13.3 cpu-protect cpu bandwidth

Use this command to configure the bandwidth for the CPU port. Use the **no** form of this command to restore the default setting.

**cpu-protect cpu bandwidth *bandwidth\_value***

**no cpu-protect cpu bandwidth**

| Parameter Description | Parameter              | Description                                                                                     |
|-----------------------|------------------------|-------------------------------------------------------------------------------------------------|
|                       | <i>bandwidth_value</i> | An integer number ranges from 0 to 100000 (PPS). Indicates the bandwidth value of the CPU port. |

**Defaults** The default CPU port bandwidth varies with products.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the CPU port bandwidth to 32000pps.

```
Ruijie# configure terminal
Ruijie(config)# cpu-protect cpu bandwidth 32000
Ruijie#show cpu-protect cpu
%cpu port bandwidth: 32000(pps)
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 13.4 cpu-protect traffic-class bandwidth

Use this command to configure the bandwidth for each priority queue. Use the **no** form of this command to restore the default setting.

**cpu-protect traffic-class** *traffic-class-num* **bandwidth** *bandwidth\_value*

**no cpu-protect traffic-class** *traffic-class-num* **bandwidth**

| Parameter Description | Parameter                | Description                                                                                     |
|-----------------------|--------------------------|-------------------------------------------------------------------------------------------------|
|                       | <i>traffic-class-num</i> | A default integer that varies with products, indicating the queue priority                      |
|                       | <i>bandwidth_value</i>   | An integer number ranges from 0 to 100000 (pps). Indicates the bandwidth value of the CPU port. |

**Defaults** The default bandwidth of each priority queue varies with products.

**Command** Global configuration mode

**Mode****Usage Guide** N/A**Configuration** The following example sets the priority queue 5 to 3500 pps.**Examples**

```
Ruijie# configure terminal
Ruijie(config)# cpu-protect traffic-class 5 bandwidth 3500
Ruijie#show cpu-protect traffic-class 5
Traffic-class   Bandwidth(pps)  Rate(pps)      Drop(pps)
-----
5               3500            0              0
```

## 13.5 cpu-protect type bandwidth

Use this command to configure the bandwidth of a specific packet.

Use the **no** form of this command to restore the default setting.

**cpu-protect type** *packet-type* **bandwidth** *bandwidth\_value*

**no cpu-protect type** *packet-type* **bandwidth**

**Parameter  
Description**

| Parameter              | Description                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------|
| <i>packet-type</i>     | Packet type, which varies with products                                                        |
| <i>bandwidth_value</i> | An integer number ranges from 0 to 32000 (pps). Indicates the bandwidth value of the CPU port. |

**Defaults** The default CPU port bandwidth varies with products.**Command** Global configuration mode**Mode****Usage Guide** N/A**Configuration** The following example sets the BPDU bandwidth to 200 pps.**Examples**

```
Ruijie# configure terminal
Ruijie(config)# cpu-protect type bpdu bandwidth 200
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
```

| Total | Total Drop |       |       |       |       |
|-------|------------|-------|-------|-------|-------|
| ----- | -----      | ----- | ----- | ----- | ----- |
| bpdu  | 6          | 200   | 0     | 0     | 0     |

**Description**

### 13.6 cpu-protect type traffic-class

Use this command to set the priority queue (PQ) of the packet.  
 Use the **no** form of this command to restore the default setting.

**cpu-protect type** *packet-type* **traffic-class** *traffic-class-num*  
**no cpu-protect type** *packet-type* **traffic-class**

| Parameter Description | Parameter                | Description                                                                             |
|-----------------------|--------------------------|-----------------------------------------------------------------------------------------|
|                       |                          | <i>packet-type</i>                                                                      |
|                       | <i>traffic-class-num</i> | An integer number varying with products. Indicates the bandwidth value of the CPU port. |

**Defaults** The default PQ varies with products.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the PQ of BPDU packets to 5.

```
Ruijie# configure terminal
Ruijie(config)# cpu-protect type bpdu traffic-class 5
Ruijie(config)#show cpu-protect type bpdu
Packet Type      Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)
Total    Total Drop
-----
-----
bpdu      5          200          0          0          0          0
```

## 14 DHCP Snooping Commands

### 14.1 clear ip dhcp snooping binding

Use this command to delete the dynamic user information from the DHCP Snooping binding database.

**clear ip dhcp snooping binding** [ *ip* ] [ *mac* ] [ **vlan** *vlan-id* ] [ **interface** *interface-id* ]

| Parameter Description | Parameter           | Description                                      |
|-----------------------|---------------------|--------------------------------------------------|
|                       | <i>mac</i>          | Specifies the user MAC address to be cleared.    |
|                       | <i>vlan-id</i>      | Specifies the ID of the VLAN to be cleared.      |
|                       | <i>ip</i>           | Specifies the IP address to be cleared.          |
|                       | <i>interface-id</i> | Specifies the ID of the interface to be cleared. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command to clear the current dynamic user information from the DHCP Snooping binding database.

 After this command is used, all the DHCP clients connecting interfaces with IP Source Guard function enabled should request IP addresses again, or they cannot access network.

**Configuration Examples** The following example clears the dynamic database information from the DHCP Snooping binding database.

```
Ruijie# clear ip dhcp snooping binding
Ruijie# show ip dhcp snooping binding
Total number of bindings: 0
MacAddress IpAddress Lease(sec) Type VLAN Interface
-----
```

| Related Commands | Command                              | Description                                                     |
|------------------|--------------------------------------|-----------------------------------------------------------------|
|                  | <b>show ip dhcp snooping binding</b> | Displays the information of the DHCP Snooping binding database. |

**Platform Description** N/A

## 14.2 ip dhcp snooping

Use this command to enable the DHCP Snooping function globally.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping**

**no ip dhcp snooping**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** The **show ip dhcp snooping** command is used to display whether the DHCP Snooping function is enabled.

**Configuration** The following example enables the DHCP Snooping function.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping
Ruijie(config)# end
```

| Related Commands | Command                      | Description                                              |
|------------------|------------------------------|----------------------------------------------------------|
|                  | <b>show ip dhcp snooping</b> | Displays the configuration information of DHCP Snooping. |
|                  | <b>ip dhcp snooping vlan</b> | Configures DHCP Snooping enabled VLAN.                   |

**Platform** N/A

**Description**

## 14.3 ip dhcp snooping bootp-bind

Use this command to enable DHCP Snooping BOOTP-bind function.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping bootp-bind**

**no ip dhcp snooping bootp-bind**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** By default, the DHCP Snooping only forwards BOOTP packets. With this function enabled, it can Snoop BOOTP packets. After the BOOTP client requests an address successfully, the DHCP Snooping adds the BOOTP user to the static binding database.

**Configuration** The following example enables the DHCP Snooping BOOTP-bind function.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping bootp-bind
Ruijie(config)# end
```

|------------------------------|-------------------------------------------|
| <b>show ip dhcp snooping</b> | Displays the DHCP Snooping configuration. |

**Platform** N/A  
**Description**

## 14.4 ip dhcp snooping check-giaddr

Use this command to enable DHCP Snooping to support the function of processing Relay requests. Use the **no** form of this command to restore the default setting.

**ip dhcp snooping check-giaddr**

**no ip dhcp snooping check-giaddr**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** After the feature is enabled, services using DHCP Snooping binding entries generated based on Relay requests, such as IP Source Guard/802.1x authentication, cannot be deployed. Otherwise, users fail to access the Internet.  
After the feature is enabled, the **ip dhcp snooping verify mac-address** command cannot be used. Otherwise, DHCP Relay requests will be discarded and as a result, users fail to obtain addresses.

**Configuration** The following example enables DHCP Snooping to support the function of processing Relay requests.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping check-giaddr
Ruijie(config)# end
```

**Related Commands**

| Command                      | Description                                                  |
|------------------------------|--------------------------------------------------------------|

**Platform** N/A

**Description**

## 14.5 ip dhcp snooping database

Use this command to configure file backup of the DHCP Snooping binding database.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping database sata0** [interval *time*]

**no ip dhcp snooping database sata0**

**Parameter Description**

| Parameter   | Description                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>time</i> | Indicates the interval of storing the database in the unit of second. The range is from 10s to 86,400s. The default value is 300s. |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** After this feature is enabled, the DHCP Snooping database can be written to the backup file of a specified type. In this way, users are able to resume communication immediately after restart of the device.

**Configuration Examples** The following example sets configures file backup of the DHCP Snooping binding database with the default interval.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping database sata0
Ruijie(config)# end
```

**Description**

## 14.6 ip dhcp snooping database write-delay

Use this command to configure the switch to write the dynamic user information of the DHCP Snooping binding database into the flash periodically.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping database write-delay** *time*

**no ip dhcp snooping database write-delay**

| Parameter Description | Parameter   | Description                                                                                                                                                               |
|-----------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>time</i> | The interval at which the system writes the dynamic user information of the DHCP Snooping database into the flash, in the range from 600 to 86,400 in the unit of seconds |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This function writes user information into flash in case of loss after restart. In that case, users need to obtain IP addresses again for normal communication.

 Too fast writing will reduce flash durability.

**Configuration Examples** The following example sets the interval at which the switch writes the user information into the flash to 3,600 seconds.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping database write-delay 3600
Ruijie(config)# end
```

|------------------|------------------------------|--------------------------------------------------------------|
|                  | <b>show ip dhcp snooping</b> | Displays the configuration information of the DHCP Snooping. |

**Platform** N/A  
**Description**

## 14.7 ip dhcp snooping database write-to-flash

Use this command to write the dynamic user information of the DHCP binding database into flash in real time.

**ip dhcp snooping database write-to-flash**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to write the dynamic user information of the DHCP binding database into flash in real time.

**Configuration Examples** The following example writes the dynamic user information of the DHCP binding database into flash.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping database write-to-flash
Ruijie(config)# end
```

| Related Commands | Command | Description |

**Description**

## 14.8 ip dhcp snooping information option

Use this command to add option82 to the DHCP request message.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping information option [ standard-format ]**

**no ip dhcp snooping information option [ standard-format ]**

| Parameter Description | Parameter              | Description                            |
|-----------------------|------------------------|----------------------------------------|
|                       | <b>standard-format</b> | The option82 uses the standard format. |

**Defaults** This function is disabled by default,

**Command Mode** Global configuration mode

**Usage Guide** This command adds option82 to the DHCP request messages based on which the DHCP server assigns IP addresses.  
By default, this function is in extended mode.

 DHCP Relay function adds option82 by default. Therefore, it is unnecessary to enable functions of DHCP Snooping option82 and DHCP Relay at the same time.

**Configuration Examples** The following example adds option82 to the DHCP request message.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping information option
Ruijie(config)# end
```

**Related Commands**

| Command                      | Description                               |
|------------------------------|-------------------------------------------|
| <b>show ip dhcp snooping</b> | Displays the DHCP Snooping configuration. |

**Platform** N/A

**Description**

## 14.9 ip dhcp snooping information option format remote-id

Use this command to set the option82 sub-option remote-id as the customized character string.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping information option format remote-id { string *ascii-string* | hostname }**

**no ip dhcp snooping information option format remote-id { string *ascii-string* | hostname }**

**Parameter Description**

| Parameter                         | Description                                                                            |
|-----------------------------------|----------------------------------------------------------------------------------------|
| <b>string</b> <i>ascii-string</i> | The content of the option82 remote-id extension format is customized character string. |
| <b>hostname</b>                   | The content of the option82 remote-id extension format hostname                        |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** This command sets the remote-id in the option82 to be added to the DHCP request message as the

customized character string. The DHCP server will assign the IP address according to the option82 information.

**Configuration Examples** The following example adds the option82 into the DHCP request packets with the content of remote-id as hostname.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping information option format remote-id hostname
```

**Related Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform Description** N/A

## 14.10 ip dhcp snooping monitor

Use this command to enable DHCP Snooping monitoring.  
Use the **no** form of this command to restore the default setting.

**ip dhcp snooping monitor**  
**no ip dhcp snooping monitor**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** After the feature is enabled, DHCP Snooping generates binding entries according to the interaction process by copying DHCP packets. It, however, does not check the validity of packets.

**Configuration Examples** The following example enables DHCP Snooping monitoring.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping monitor
Ruijie(config)# end
```

**Related Commands**

| Command | Description |
|---------|-------------|

**Platform** N/A

**Description**

## 14.11 ip dhcp snooping suppression

Use this command to set the port to be the suppression status.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping suppression**

**no ip dhcp snooping suppression**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode/WLAN security configuration mode

**Usage Guide** This command denies all DHCP request messages under the port, that is, all the users under the port are prohibited to request IP addresses through DHCP.  
This command is only supported on Layer 2 switch interfaces and aggregate ports (APs).

**Configuration** The following example sets **fastEthernet 0/2** and **WLAN 1** to be in the suppression status.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastEthernet 0/2
Ruijie(config-if)# ip dhcp snooping suppression
Ruijie(config-if)# end
Ruijie# configure terminal
Ruijie(config)# wlansec 1
Ruijie(config-wlansec)# ip dhcp snooping suppression
Ruijie(config-if-wlansec)# end
```

| Related Commands | Command                      | Description                               |
|------------------|------------------------------|-------------------------------------------|
|                  | <b>show ip dhcp snooping</b> | Displays the DHCP Snooping configuration. |

**Platform Description** N/A

## 14.12 ip dhcp snooping trust

Use this command to set the trusted ports for DHCP Snooping.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping trust**  
**no ip dhcp snooping trust**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** All ports are untrusted by default.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to set a port as a trusted port. The DHCP response messages received under the trust port are forwarded normally, but the response messages received under the untrusted port will be discarded. This command is only supported on Layer 2 switch interfaces and aggregate ports (APs).

**Configuration** The following example sets fastEthernet 0/1 as a trusted port:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ip dhcp snooping trust
Ruijie(config-if)# end
```

| Related<br>Commands | Command | Description                  |
|---------------------|---------|------------------------------|
|                     |         | <b>show ip dhcp snooping</b> |

**Platform** N/A

**Description**

## 14.13 ip dhcp snooping verify mac-address

Use this command to check whether the source MAC address of the DHCP request message matches against the **client addr** field of the DHCP message.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping verify mac-address**  
**no ip dhcp snooping verify mac-address**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** This function is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** Use this command to check the source MAC address of the DHCP request message. If the MAC address in the link-layer header is different from the CHADDR (Client MAC Address), the check fails ,and the packets will be discarded.

**Configuration** The following example enables the check of the source MAC address of the DHCP request message.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping verify mac-address
Ruijie(config)# end
```

**Related Commands**

| Command                      | Description                               |

| <b>show ip dhcp snooping</b> | Displays the DHCP Snooping configuration. |

**Platform** N/A

**Description**

## 14.14 ip dhcp snooping vlan

Use this command to enable DHCP Snooping for the specific VLAN.

Use the **no** form of this command to restore the default setting.

**ip dhcp snooping vlan** {vlan-rng | { vlan-min [ vlan-max ] } }

**no ip dhcp snooping vlan** {vlan-rng | { vlan-min [ vlan-max ] } }

**Parameter Description**

| Parameter       | Description                             |
|-----------------|-----------------------------------------|
| <i>vlan-rng</i> | VLAN range of effective DHCP Snooping   |
| <i>vlan-min</i> | Minimum VLAN of effective DHCP Snooping |
| <i>vlan-max</i> | Maximum VLAN of effective DHCP Snooping |

**Defaults** By default, once the DHCP Snooping is enabled globally, it takes effect for all VLANs.

**Command** Global configuration mode  
**Mode**

**Usage Guide** Use this command to enable DHCP Snooping for specified VLANs globally.

**Configuration** The following example enables the DHCP Snooping function in VLAN 1000.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping vlan 1000
Ruijie(config)# end
```

The following example enables the DHCP Snooping function from VLAN1 to VLAN10.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping vlan 1-10
Ruijie(config)# end
```

## 14.15 renew ip dhcp snooping database

Use this command to import the information in current flash to the DHCP Snooping binding database manually as needed.

**renew ip dhcp snooping database**

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to import the flash file information to the DHCP Snooping database in real time.

 Records out of lease time and repeated will be neglected.

**Configuration Examples** The following example imports the flash file information to the DHCP Snooping database.

```
Ruijie# renew ip dhcp snooping database
```

## 14.17 show ip dhcp snooping binding

Use this command to display the information of the DHCP Snooping binding database.

**show ip dhcp snooping binding**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display all the information of the DHCP Snooping binding database.

**Configuration** 1: The following example displays the information of the DHCP Snooping binding database.

**Examples**

```
Ruijie# show ip dhcp snooping binding
Total number of bindings: 1
NO.  MACADDRESS      IPADDRESS      LEASE (SEC)   TYPE          VLAN
INTERFACE
-----
-----
1     0000.0000.0001     1.1.1.1       78128         DHCP-Snooping 1
GigabitEthernet 0/1
2     0000.0000.0002     2.2.2.2       78111         DHCP-Snooping 1   WLAN 1
```

2: For products supporting QINQ termination, the following example displays the information of the inner VLAN.

```
Ruijie# show ip dhcp snooping binding
Total number of bindings: 1
NO.  MACADDRESS      IPADDRESS      LEASE (SEC)   TYPE          VLAN
INNER-VLAN INTERFACE
-----
-----
1     0000.0000.0001     1.1.1.1       78128         DHCP-Snooping 1   10
GigabitEthernet 0/1
```

3: For products supporting VXLAN, the following example displays the information of the VXLAN.

```
Ruijie# show ip dhcp snooping binding
Total number of bindings: 1
NO.  MACADDRESS      IPADDRESS      LEASE (SEC)   TYPE          VLAN
INNER-VLAN VXLAN  INTERFACE
-----
-----
1     0000.0000.0001     1.1.1.1       78128         DHCP-Snooping 0   0
```

1 GigabitEthernet 0/1

| Parameter                | Description                                                                                           |
|--------------------------|-------------------------------------------------------------------------------------------------------|
| Total number of bindings | The total number of bindings in the DHCP Snooping database.                                           |
| NO.                      | The record order.                                                                                     |
| MacAddress               | The MAC address of the user.                                                                          |
| IpAddress                | The IP address of the user.                                                                           |
| Lease(sec)               | The lease time of the record.                                                                         |
| Type                     | The record type.                                                                                      |
| VLAN                     | The VLAN where the user belongs.                                                                      |
| INNER-VLAN               | The inner VLAN of the user. It is applicable to all QINQ-termination products.                        |
| VXLAN                    | The VXLAN where the user belongs.                                                                     |
| Interface                | The user's connection interface. It can be a either a wired access interface or wireless access WLAN. |

**Description**

## 15 DHCPv6 Snooping Commands

### 15.1 clear ipv6 dhcp snooping binding

Use this command to clear all the user information in the DHCPv6 Snooping binding database.

**clear ipv6 dhcp snooping binding** [ *mac* | **vlan** *vlan-id* | *ipv6-address* | **interface** *interface-id* ]

| Parameter Description | Parameter           | Description                                 |
|-----------------------|---------------------|---------------------------------------------|
|                       | <i>mac</i>          | Specifies the MAC address to be deleted.    |
|                       | <i>vlan-id</i>      | Specifies the ID of the VLAN to be cleared. |
|                       | <i>ipv6-address</i> | Specifies the IPv6 address to be cleared.   |
|                       | <i>interface-id</i> | Specifies the interface to be cleared.      |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to clear the generated user information in the DHCPv6 Snooping binding database.

**Configuration Examples** The following example clears all the user information in the DHCPv6 Snooping binding database.

```
Ruijie# clear ipv6 dhcp snooping binding
Ruijie# show ipv6 dhcp snooping binding
NO.  MacAddress      IPv6 Address  Lease(sec)  VLAN  Interface
FilterType  FilterStatus
-----
-----
Total number of bindings: 0
```

**Description**

### 15.2 clear ipv6 dhcp snooping prefix

Use this command to clear all the user information in the DHCPv6 Snooping prefix list.

**clear ipv6 dhcp snooping prefix** [ *mac* | **vlan** *vlan-id* | *ipv6-prefix* | **interface** *interface-id* ]

**Parameter  
Description**

| Parameter           | Description                                 |
|---------------------|---------------------------------------------|
| <i>mac</i>          | Specifies the MAC address to be deleted.    |
| <i>vlan-id</i>      | Specifies the ID of the VLAN to be cleared. |
| <i>ipv6-address</i> | Specifies the IPv6 address to be cleared.   |
| <i>interface-id</i> | Specifies the interface to be cleared.      |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** This command is used to clear the generated user information in the DHCPv6 Snooping prefix list.

**Configuration** The following example clears all the user information in the DHCPv6 Snooping binding database

**Examples**

```
Ruijie# clear ipv6 dhcp snooping prefix
Ruijie# show ipv6 dhcp snooping prefix
NO. MacAddress      IPv6 Prefix Lease(sec) VLAN Interface
FilterType FilterStatus
-----
-----
Total number of prefixes: 0
```

Description** N/A

## 15.3 clear ipv6 dhcp snooping statistics

Use this command to clear the statistical information of the DHCPv6 packets.

**clear ipv6 dhcp snooping statistics**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command** Privileged EXEC mode  
**Mode**

**Usage Guide** This command is used to clear the statistical information of the DHCPv6 packets.

**Configuration** The following example clears the statistical information of the DHCPv6 packets.

**Examples**

```
Ruijie# clear ipv6 dhcp snooping statistics
Ruijie# show ipv6 dhcp snooping statistics
Packets Processed by DHCPv6 Snooping = 0
Packets Dropped Because
Received on untrusted ports      = 0
Relay forward                    = 0
No binding entry                 = 0
Binding fail                     = 0
Unknown packet                   = 0
Unknown output interface        = 0
No enough memory                 = 0
Admin filter-dhcpv6-pkt         = 0
```

**Related  
Commands**

**Platform** N/A  
**Description**

## 15.4 ipv6 dhcp snooping

Use this command to enable the DHCPv6 Snooping function globally.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping**

**no ipv6 dhcp snooping**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command** Global configuration mode  
**Mode**

**Usage Guide** The **show ip dhcpv6 snooping** command is used to display whether the DHCPv6 Snooping function is enabled.

**Configuration** The following example enables the DHCPv6 Snooping function globally.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 dhcp snooping
Ruijie(config)# end
```

| Related Commands | Command | Description                    |
|------------------|---------|--------------------------------|
|                  |         | <b>show ipv6 dhcp snooping</b> |

**Platform** N/A

**Description**

## 15.5 ipv6 dhcp snooping binding-delay

Use this command to add the dynamic binding entry to the hardware filtering list after the delay.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping binding-delay** *seconds*

**no ipv6 dhcp snooping binding-delay**

| Parameter Description | Parameter | Description    |
|-----------------------|-----------|----------------|
|                       |           | <i>seconds</i> |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** By default, the dynamic binding entries are added to the hardware filtering list in real time. With this command configured, if no IPv6 address conflict is detected within the specified time, the dynamic binding entries are added to the hardware filtering list.

**Configuration** The following example sets the delay to 10 seconds.

**Examples**

```
Ruijie(config)# ipv6 dhcp snooping binding-delay 10
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  |         | N/A         |

**Platform** N/A

**Description**

## 15.6 ipv6 dhcp snooping database write-delay

Use this command to write the dynamic user information of the DHCPv6 Snooping binding database into the flash periodically.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping database write-delay** *time*

**no ipv6 dhcp snooping database write-delay**

### Parameter Description

| Parameter   | Description                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>time</i> | The interval ranging from 600 to 86,400 in the unit of seconds, at which the system writes the dynamic user information of the DHCP Snooping database into the flash. |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** This function writes user information into flash and can avoid loss after restart. In that case, users need to obtain IP addresses again for normal communication.

 Too fast writing will reduce flash durability.

**Configuration Examples** The following example sets the interval at which the switch writes the user information into the flash to 3,600 seconds.

```
Ruijie# configure terminal
Ruijie(config)# ip dhcp snooping database write-delay 3600
Ruijie(config)# end
```

## 15.8 ipv6 dhcp snooping information option

Use this command to add option18/37 to the DHCPv6 request packets.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping information option [ standard-format ]**

**no ipv6 dhcp snooping information option [ standard-format ]**

|                              |                                                                                                                                                                                                                                                                              |                                           |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b>                                                                                                                                                                                                                                                             | <b>Description</b>                        |
|                              | <b>standard-format</b>                                                                                                                                                                                                                                                       | The Option18/37 uses the standard format. |
| <b>Defaults</b>              | This function is disabled by default.                                                                                                                                                                                                                                        |                                           |
| <b>Command Mode</b>          | Global configuration mode                                                                                                                                                                                                                                                    |                                           |
| <b>Usage Guide</b>           | With this command configured, the option18/37 will be added to the DHCPv6 request packets and the DHCPv6 server will assign the addresses according to the option18/37 information. Use this command without parameter <b>standard-format</b> to enable the standard format. |                                           |

 DHCPv6 Relay function adds option18/37 by default. Therefore, it is unnecessary to enable functions of DHCP Snooping option18/37 and DHCPv6 Relay at the same time.

**Configuration** The following example adds the option18/37 into the DHCPv6 packets.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 dhcp snooping information option
Ruijie(config)# end
Ruijie# show ipv6 dhcp snooping
Switch DHCPv6 snooping status :ENABLE
DHCPv6 snooping vlan: 1-4094
DHCPv6 snooping database write-delay time: 0 seconds
DHCPv6 snooping option 18/37 status: ENABLE
DHCPv6 snooping link detection :DISABLE
Interface           Trusted   Filter DHCP
-----
FastEthernet0/10    yes      DISABLE
```

| <b>show ipv6 dhcp snooping</b> | Displays the configuration information of the DHCPv6 Snooping. |

**Platform** N/A

**Description**

## 15.9 ipv6 dhcp snooping information option format remote-id

Use this command to add option37 remote-id customized character string into the DHCPv6 request packets.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping information option format remote-id [ string *ascii-string* | hostname ]**

**no ipv6 dhcp snooping information option format remote-id [ string *ascii-string* | hostname ]**

**Parameter  
Description**

| Parameter                         | Description                                                                        |
|-----------------------------------|------------------------------------------------------------------------------------|
| <b>string <i>ascii-string</i></b> | The content of Option37 remote-id extension format is customized character string. |
| <b>hostname</b>                   | The content of Option37 remote-id extension format is hostname.                    |

**Defaults** This function is disabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** With this command configured, the option37 remote-id will be added to the DHCPv6 request packets with the content as the customized and the DHCPv6 server will assign the addresses according to the option37 information.

**Configuration Examples** The following example adds the option37 remote-id to the DHCPv6 request packets with the content being hostname.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 dhcp snooping information option format remote-id
hostname
```

## 15.10 ipv6 dhcp snooping filter-dhcp-pkt

Use this command to filter all received DHCPv6 request packets.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping filter-dhcp-pkt**

**no ipv6 dhcp snooping filter-dhcp-pkt**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to filter all received DHCPv6 request packets, that is, to avoid all the DHCPv6 users on this interface to apply for the addresses.  
This command is valid only on 2-layer wired switch ports, aggregate ports and sub interfaces as well as in air interfaces.

**Configuration Examples** The following example filters all DHCPv6 request packets on interface FastEthernet 0/1 and WLAN 1.

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ipv6 dhcp snooping filter-dhcp-pkt
Ruijie(config-if-GigabitEthernet 0/2)# end
```

**Description**

## 15.11 ipv6 dhcp snooping link-detection

Use this command to clear the dynamic binding entry on an interface when the interface links down. Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping link-detection**  
**no ipv6 dhcp snooping link-detection**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** By default, the dynamic binding entries are not cleared on a wired interface when the interface links down. With this function enabled, the dynamic binding entries are auto-cleared on an interface when the interface is in the LINK DOWN status.

**Configuration Examples** The following example clears the dynamic binding entry on a wired interface when the interface is in the LINK DOWN status.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 dhcp snooping link-detection
```

## 15.12 ipv6 dhcp snooping trust

Use this command to set the specified DHCPv6 Snooping ports as the trusted ports.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping trust**

**no ipv6 dhcp snooping trust**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** All ports are untrusted ports by default.

**Command Mode** Interface configuration mode

**Usage Guide**

1. Use this command to set a port as a trusted port. The DHCPv6 Server response messages received under the trust port are forwarded normally, but the response messages received under the untrusted port will be discarded.
2. This command is valid only on Layer 2 wired switch ports and aggregate ports.

**Configuration** The following example sets **FastEthernet 0/1** as a trust port:

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if)# ipv6 dhcp snooping trust
Ruijie(config-if)# end
```

| Related Commands | Command                        | Description                                 |
|------------------|--------------------------------|---------------------------------------------|
|                  | <b>show ipv6 dhcp snooping</b> | Displays the DHCPv6 Snooping configuration. |

**Platform Description** N/A

## 15.13 ipv6 dhcp snooping vlan

Use this command to enable DHCPv6 Snooping for the specific VLAN.

Use the **no** form of this command to disable this function.

**ipv6 dhcp snooping vlan** { *vlan-rng* | { *vlan-min* [ *vlan-max* ] } }

**no ipv6 dhcp snooping vlan** { *vlan-rn* | { *vlan-min* [ *vlan-max* ] } }

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                 |                            |
|-----------------|----------------------------|
| <i>vlan-rng</i> | Sets the valid VLAN range. |
| <i>vlan-min</i> | Minimum VLAN ID            |
| <i>vlan-max</i> | Maximum VLAN ID            |

**Defaults** By default, once the DHCPv6 Snooping is enabled globally, it takes effect for all VLANs.

**Command** Global configuration mode

**Mode**

**Usage Guide** With the global DHCPv6 snooping enabled, this function is enabled in all VLANs by default.

**Configuration** The following example enables the DHCPv6 Snooping function in VLAN 1000.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ipv6 dhcp snooping vlan 1000
Ruijie(config)# end
```

The following example enables the DHCPv6 Snooping function in VLAN 1 to VLAN 10.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 dhcp snooping vlan 1-10
Ruijie(config)# end
```

**Description**

## 15.14 ipv6 dhcp snooping vlan information option change-vlan-to vlan

Use this command to enable the function of adding the option18 interface-is into the DHCP request packets and change the VLAN to the specified VLAN for the forwarding.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping vlan *vlan-id* information option change-vlan-to vlan *vlan-id***

**no ipv6 dhcp snooping vlan *vlan-id* information option change-vlan-to vlan *vlan-id***

**Parameter  
Description**

| Parameter      | Description                                  |
|----------------|----------------------------------------------|
| <i>vlan-id</i> | Specifies the ID of the VLAN to be replaced. |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** With this command enabled, the option18 interface-id will be added into the DHCPv6 request packets and the VLAN will be changed to the specified one and the DHCP server will assign the addresses according to the optionq8 information.

**Configuration Examples** The following example adds the option18 interface-id into the DHCPv6 request packets and changes the VLAN4094 in the option to VLAN 4093.

```
Ruijie# configure terminal
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ipv6 dhcp snooping vlan 4094 information option
change-vlan-to vlan 4093
Ruijie(config-if)# end
```

**Description**

## 15.15 ipv6 dhcp snooping vlan information option format-type

### interface-id string

Use this command to enable the function of adding the option18 into the DHCP request packets and filling the option18 interface-id with the content being the user-defined (the storage format is ASCII) and performing the packet forwarding.

Use the **no** form of this command to restore the default setting.

**ipv6 dhcp snooping vlan** *vlan-id* **information option format-type interface-id string** *ascii-string*  
**no ipv6 dhcp snooping vlan** *vlan-id* **information option format-type interface-id string**  
*ascii-string*

**Parameter Description**

| Parameter           | Description                                       |
|---------------------|---------------------------------------------------|
| <i>vlan-id</i>      | The VLAN where the DHCPv6 request packets are     |
| <i>ascii-string</i> | User-defined content for filling the interface-id |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** With this command configured, the option18 interface-id will be added into the DHCPv6 request packets with the content being user-defined and the DHCPv6 server will assign the addresses according to the option18 information.

**Configuration** The following example adds the option18 interface-id to the DHCPv6 request packets with the content being *port-name*.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if)# ipv6 dhcp snooping vlan 4094 information option format-type
interface-id string port-name
Ruijie(config-if)# end
```

## 15.16 renew ipv6 dhcp snooping database

Use this command to import the information in current flash to the DHCPv6 Snooping binding database manually as needed.

**renew ipv6 dhcp snooping database**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** This command is used to import the flash file information to the DHCPv6 Snooping database in real time.

 Records out of lease time and repeated will be neglected.

**Configuration** The following example imports the flash file information to the DHCPv6 Snooping database.

**Examples**

```
Ruijie# renew ipv6 dhcp snooping database
```

## 15.17 show ipv6 dhcp snooping

Use this command to display the setting of the DHCPv6 Snooping.

**show ipv6 dhcp snooping**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the setting of the DHCPv6 Snooping.

```
Ruijie# show ipv6 dhcp snooping
Switch DHCPv6 snooping status :ENABLE
DHCPv6 snooping vlan: 1-4094
DHCPv6 snooping database write-delay time: 0 seconds
DHCPv6 snooping option 18/37 status: DISABLE
DHCPv6 snooping link detection :DISABLE
Interface           Trusted   Filter DHCP
-----
FastEthernet0/10    yes      DISABLE
```

## 15.18 show ipv6 dhcp snooping vlan

Use this command to display the VLAN with DHCPv6 Snooping function disabled.

**show ipv6 dhcp snooping vlan**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|     |     |
|-----|-----|
| N/A | N/A |
|-----|-----|

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display the VLAN with DHCPv6 Snooping function disabled.

**Configuration** The following example displays the VLAN with DHCPv6 Snooping function disabled.

**Examples** Ruijie#show ipv6 dhcp snooping vlan

```
VLAN Name      Closed
-----
```

```
2   VLAN 2      YES
```

| Field | Description                                    |
|-------|------------------------------------------------|
| VLAN  | VLAN ID                                        |
| NAME  | VLAN name                                      |
| Close | Indicates whether DHCPv6 Snooping is disabled. |

## 15.19 show ipv6 dhcp snooping binding

Use this command to display the information of the DHCPv6 Snooping binding database.

**show ipv6 dhcp snooping binding** [ *mac* ] [ **vlan** *vlan-id* ] [ *ipv6-address* ] [ **interface** *interface-id* ]

| Parameter Description | Parameter           | Description                              |
|-----------------------|---------------------|------------------------------------------|
|                       | <i>mac</i>          | Displays the MAC address binding entry.  |
|                       | <i>vlan_id</i>      | Displays the VLAN binding entry.         |
|                       | <i>ipv6-address</i> | Displays the IPv6 address binding entry. |
|                       | <i>interface-id</i> | Displays the interface binding entry.    |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the information of the DHCP Snooping binding database.

### Examples

```
Ruijie# show ipv6 dhcp snooping binding
Total number of bindings: 1
NO.   MacAddress          IPv6 Address              Lease (sec)
VLAN  Interface
-----
-----
1     00d0.f801.0101       2001::10                  42368          2
GigabitEthernet 0/1
```

## 15.20 show ipv6 dhcp snooping prefix

Use this command to display all user information in the DHCPv6 Snooping prefix list.

**show ipv6 dhcp snooping prefix** [ *mac* | **vlan** *vlan-id* | *ipv6-prefix* | **interface** *interface-id* ]

| Parameter Description | Parameter           | Description                             |
|-----------------------|---------------------|-----------------------------------------|
|                       | <i>mac</i>          | Displays the MAC address prefix entry.  |
|                       | <i>vlan_id</i>      | Displays the VLAN prefix entry.         |
|                       | <i>ipv6-prefix</i>  | Displays the IPv6 address prefix entry. |
|                       | <i>interface-id</i> | Displays the interface prefix entry.    |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example displays all user information in the DHCPv6 Snooping prefix list.

```
Ruijie# show ipv6 dhcp snooping prefix
Total number of prefix: 1

NO.   MacAddress          IPv6 Prefix          Lease(sec)  VLAN   Interface
-----
1     00d0.f801.0101     2001:2002::          42368      2     GigabitEthernet 0/1
```

| Related Commands | Command | Description |

**Platform Description** N/A

## 15.21 show ipv6 dhcp snooping statistics

Use this command to display the statistical information of the DHCPv6 packets.

**show ipv6 dhcp snooping statistics**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the statistical information of the DHCPv6 packets.

```

Examples Ruijie# show ipv6 dhcp snooping statistics
Packets Processed by DHCPv6 Snooping = 0
Packets Dropped Because
Received on untrusted ports      = 0
Relay forward                    = 0
No binding entry                = 0
Binding fail                    = 0
Unknown packet                  = 0
Unknown output interface        = 0
No enough memory                = 0
Admin filter-dhcpv6-pkt        = 0
    
```

| Field                       | Description                                                                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Received on untrusted ports | The discarded server response packets on the untrust port.                                                                                    |
| Relay forward               | The packets that have been relayed once are discarded.                                                                                        |
| No binding entry            | The binding entries of the release/decline packets are in-existent or error and the packets are discarded.                                    |
| Binding fail                | The entry binding fails and the packets are discarded due to a lack of the hardware resources.                                                |
| Unknown packet              | The unknown DHCP packets.                                                                                                                     |
| Unknown output interface    | The packets on the unknown output interface. The MAC address for the interface is not found or the trust port is not configured.              |
| No enough memory            | There is no enough memory.                                                                                                                    |
| Admin filter-dhcpv6-pkt     | The filtered DHCPv6 packets configured by the administrator. Use the <b>ipv6 dhcp snooping filter-dhcp-pkt</b> command to filter the packets. |

**Related Commands**

|---------|-------------|
| N/A     | N/A         |

**Platform Description** N/A

## 16 ARP-Check Commands

### 16.1 arp-check

Use this command to enable the ARP check function on the Layer 2 interface.

Use the **no** form of this command to restore the default setting.

**arp-check**

**no arp-check**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command mode** Interface configuration mode

**Usage Guide** The ARP check function generates the ARP filtering information according to legal user information, implementing the illegal ARP packet filtering on the network.

**Configuration** This following example enables the APR check function on interface GigabitEthernet 0/1.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# arp-check
Ruijie(config-if-GigabitEthernet 0/1)# end
```

| Related Commands | Command                               | Description                     |
|------------------|---------------------------------------|---------------------------------|
|                  | <b>show interfaces arp-check list</b> | Displays the ARP check entries. |

**Platform** N/A

**Description**

### 16.2 show interfaces arp-check list

Use this command to display the ARP check entries on the Layer 2 interface.

**show { interfaces [ *interface-type interface-number* ] } arp-check list**

| Parameter Description | Parameter             | Description          |
|-----------------------|-----------------------|----------------------|
|                       | <i>interface-type</i> | Wired interface type |

|                         |                        |
|-------------------------|------------------------|
| <i>interface-number</i> | Wired interface number |
|-------------------------|------------------------|

**Command mode** Privileged EXEC mode

**Usage Guide** Use this command to display the ARP check entries.

**Configuration Examples** The following example displays the ARP check entries.

```
Ruijie(config)#show interfaces arp-check list
INTERFACE                SENDER MAC      SENDER IP      POLIC
Y SOURCE
-----
-----
GigabitEthernet 0/1      00D0.F800.0003  192.168.1.3
address-bind
GigabitEthernet 0/1      00D0.F800.0001  192.168.1.1
port-security
GigabitEthernet 0/4                192.168.1.3
port-security
GigabitEthernet 0/5      00D0.F800.0003  192.168.1.3
address-bind
GigabitEthernet 0/7      00D0.F800.0006  192.168.1.6      AAA
ip-auth-mode
GigabitEthernet 0/8      00D0.F800.0007  192.168.1.7      GSN
```

| Field         | Description         |
|---------------|---------------------|
| INTERFACE     | Interface name      |
| SENDER MAC    | Source MAC address  |
| SENDER IP     | Source IP address   |
| POLICY SOURCE | Source of the entry |

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 17 DAI Commands

### 17.1 ip arp inspection trust

Use this command to configure the L2 port to a trusted port.

Use the **no** form of this command to restore the L2 port to an untrusted port.

**ip arp inspection trust**

**no ip arp inspection trust**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The L2 port is untrusted.

**Command Mode** Interface configuration mode

**Usage Guide** If it is necessary to make the ARP message received by some interface pass the DAI inspection unconditionally, you can set the interface to a trusted port, indicating that you do not need to check whether the ARP message received by this interface is legal.

**Configuration Examples** The following example sets the gigabitEthernet 0/19 interface as the trusted port.

```
Ruijie# configure terminal
Ruijie(config)# interface gigabitEthernet 0/19
Ruijie(config-if-GigabitEthernet 0/19)# ip arp inspection trust
Ruijie(config-if-GigabitEthernet 0/19)# end
```

| Related Commands | Command                                 | Description                                                                                                   |
|------------------|-----------------------------------------|---------------------------------------------------------------------------------------------------------------|
|                  | <b>show ip arp inspection interface</b> | Displays related DAI information on the interface, including the trust state and rate limit of the interface. |

**Platform Description** N/A

### 17.2 ip arp inspection vlan

Use this command to configure the DAI function on the VLAN.

Use the **no** form of this command to disable this function.

```
ip arp inspection vlan { vlan-id | word }
no ip arp inspection vlan { vlan-id | word }
```

**Parameter Description**

| Parameter      | Description                                    |
|----------------|------------------------------------------------|
| <i>vlan-id</i> | VLAN ID, ranging from 1 to 4094                |
| <i>word</i>    | String of the VLAN range, such as 1,3-5,7,9-11 |

**Defaults** The DAI function on all VLANs is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** To make this command take effect, you need to enable the ARP Check function first,

 Not all ports of the VLAN support the ARP packet detection function. For example, the DHCP Snooping Trust port does not support any security detection, including this function.

**Configuration Examples** The following example detects the received ARP packets on the VLAN1 interfaces:

```
Ruijie# configure terminal
Ruijie(config)# ip arp inspection
Ruijie(config)# ip arp inspection vlan 1
Ruijie(config)# end
```

**Related Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform Description** N/A

## 17.3 show ip arp inspection vlan

Use this command to verify whether the DAI function on the VLAN is enabled.

```
show ip arp inspection vlan [ vlan-id | word ]
```

**Parameter Description**

| Parameter      | Description                                    |
|----------------|------------------------------------------------|
| <i>vlan-id</i> | VLAN ID, ranging from 1 to 4094                |
| <i>word</i>    | String of the VLAN range, such as 1,3-5,7,9-11 |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** Use this command to verify whether the DAI function on the VLAN is enabled.

**Configuration** The following example verifies whether the DAI function on the VLAN is enabled:

```
Examples Ruijie# show ip arp inspection vlan
Vlan      Configuration
-----  -
1                               Active
```

Parameter Description:

| Parameter     | Description                    |
|---------------|--------------------------------|
| Vlan          | VLAN number.                   |
| Configuration | DAI status (active / inactive) |

**Related Commands**

| Command | Description |
|---------|-------------|

**Description**

## 17.4 show ip arp inspection interface

Use this command to verify whether the interface is a DAI trust interface.

**show ip arp inspection interface**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command** Privileged EXEC mode  
**Mode**

**Usage Guide** Use this command to verify whether the interface is a DAI trust interface.

**Configuration** The following example verifies the DAI trust state of all :

```
Examples Ruijie#show ip arp inspection interface
Interface      Trust State
-----  -
GigabitEthernet 0/1    Untrusted
Default                               Untrusted
```

Parameter Description:

| Parameter   | Description      |
|-------------|------------------|
| Interface   | Interface name.  |
| Trust State | DAI trust state. |

## 18 IP Source Guard Commands

### 18.1 ip source binding

Use this command to add static user information to IP source address binding database.

Use the **no** form of this command to delete static user information from IP source address binding database.

**ip source binding** *mac-address* { **vlan** *vlan-id* } *ip-address* { **interface** *interface-id* | **ip-mac** | **ip-only** }

**no ip source binding** *mac-address* { **vlan** *vlan-id* } *ip-address* { **interface** *interface-id* | **ip-mac** | **ip-only** }

#### Parameter Description

| Parameter           | Description                         |
|---------------------|-------------------------------------|
| <i>mac-address</i>  | Adds user MAC address statically.   |
| <i>vlan-id</i>      | Adds user VLAN ID statically.       |
| <i>ip-address</i>   | Adds user IP address statically.    |
| <i>interface-id</i> | Adds user interface ID statically.  |
| <b>ip-mac</b>       | The global binding type is IP+MAC   |
| <b>ip-only</b>      | The global binding type is IP only. |

**Defaults** No static address is added by default.

**Command Mode** Global configuration mode

**Usage Guide** This command allows specific clients to go through IP source guard detection instead of DHCP. This command is supported on the wired L2 switching port, AP port, and sub interface. This command enables global binding for IP source guard so that specific clients will get detected on all interfaces.

 A static IPv6 source binding is valid either on wired interfaces or in global configuration mode.

 A new binding will overwrite the old one sharing the same configuration.

**Configuration** The following example adds the interface ID of static users.

**Examples**

```
Ruijie# configure terminal
Ruijie(config)# ip source binding 0000.0000.0001 vlan 1 1.1.1.1 interface
GigabitEthernet 0/1
Ruijie(config)# end
```

The following example adds static user information based on IP-MAC binding.

```
Ruijie# configure terminal
Ruijie(config)# ip source binding 0000.0000.0001 vlan 1 1.1.1.1 ip-mac
Ruijie(config)# end
```

The following example adds static user information based on IP binding.

```
Ruijie# configure terminal
Ruijie(config)# ip source binding 0000.0000.0001 vlan 1 1.1.1.1 ip-only
Ruijie(config)# end
```

Commands**

| Command                       | Description                                                         |
|-------------------------------|---------------------------------------------------------------------|
| <b>show ip source binding</b> | Displays the binding information of IP source address and database. |

**Platform** N/A

**Description**

## 18.2 ip verify source

Use this command to enable IP Source Guard function on the interface.

Use the **no** form of this command to restore the default setting.

**ip verify source [ port-security ]**

**no ip verify source**

**Parameter  
Description**

| Parameter            | Description                                              |
|----------------------|----------------------------------------------------------|
| <b>port-security</b> | Configures IP Source Guard to do IP+MAC-based detection. |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** This command enables IP Source Guard function on the interface to do IP-based or IP+MAC-based

detection.

This command is supported on the wired L2 switching port, AP port, and sub interface

 IP Source Guard takes effect only on DHCP Snooping untrusted port. In other words, IP Source Guard does not take effect when configuring it on Trust port or the port which is not controlled by DHCP Snooping.

### Configuration

The following example enables IP-based IP Source Guard function.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip verify source
Ruijie(config-if)# end
```

The following example enables IP+MAC-based IP Source Guard function.

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ip verify source port-security
Ruijie(config-if)# end
```

### Related Commands

| Command                      | Description                                       |
|------------------------------|---------------------------------------------------|
| <b>show ip verify source</b> | Displays user filtering entry of IP Source Guard. |

### Platform

N/A

### Description

## 18.3 ip verify source exclude-vlan

Use this command to exclude a VLAN from the IP source guard configuration on the port.

Use the **no** form of this command to restore the function.

**ip verify source exclude-vlan** *vlan-id*

**no ip verify source exclude-vlan** *vlan-id*

### Parameter Description

| Parameter      | Description                                                     |
|----------------|-----------------------------------------------------------------|
| <i>vlan-id</i> | The ID of VLAN excluded from the IP source guard configuration. |

### Defaults

This function is disabled by default.

### Command Mode

Interface configuration mode

### Usage Guide

- This command is used to exclude a VLAN from the IP source guard configuration. IP packets in

this VLAN are forwarded without being checked and filtered.

- Once the IP source guard function is disabled, the excluded VLAN is cleared automatically.
- This command is supported on the wired L2 switching port, AP port, and sub interface.

 Only when the IP source guard configuration is enabled on the port can a VLAN be excluded.

**Configuration Examples** The following example configuration configures the IP source guard configuration for the port and excludes a VLAN.

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ip verify source
Ruijie(config-if-GigabitEthernet 0/1)# ip verify exclude-vlan 1
Ruijie(config-if)# end
```

**Description**

## 18.4 show ip source binding

Use this command to display the binding information of IP source addresses and database.

**show ip source binding** [ *ip-address* ] [ *mac-address* ] [ **dhcp-snooping** ] [ **static** ] [ **vlan** *vlan-id* ] [ **interface** *interface-id* ]

**Parameter Description**

| Parameter            | Description                                                   |
|----------------------|---------------------------------------------------------------|
| <i>ip-address</i>    | Displays user binding information of corresponding IP.        |
| <i>mac-address</i>   | Displays user binding information of corresponding MAC.       |
| <b>dhcp-snooping</b> | Displays binding information of dynamic user.                 |
| <b>static</b>        | Displays binding information of static user.                  |
| <i>vlan-id</i>       | Displays user binding information of corresponding VLAN.      |
| <i>interface-id</i>  | Displays user binding information of corresponding interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the binding information of IP source guard addresses and database.

```
Ruijie# show ip source binding static
Ruijie#show ip source binding static
Total number of bindings: 5
NO.      MACADDRESS      IPADDRESS      LEASE (SEC)    TYPE      VLAN      INTERFACE
-----
1        0001.0002.0001   1.2.3.2        Infinite       Static    1         Global
2        0001.0002.0002   1.2.3.3        Infinite       Static    1         GigabitEthernet 0/5
3        0001.0002.0003   1.2.3.4        Infinite       Static    1         Global
4        0001.0002.0004   1.2.3.5        Infinite       Static    1         Global
```

**Related Commands**

| Command                  | Description                   |
|--------------------------|-------------------------------|
| <b>ip source binding</b> | Sets the binding static user. |

**Platform** N/A

**Description**

## 18.5 show ip verify source

Use this command to display user filtering entry of IP Source Guard.

**show ip verify source** [ **interface** *interface-id* ]

**Parameter Description**

| Parameter           | Description                                               |
|---------------------|-----------------------------------------------------------|
| <i>interface-id</i> | Displays user filtering entry of corresponding interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** If IP Source Guard is not enabled on the corresponding interface, the printing information will be shown on the terminal as: "IP source guard is not configured on the interface FastEthernet 0/10"  
Now, IP Source Guard supports the following filtering modes:  
**inactive-restrict-off**: the IP Source Guard is disabled on bound interfaces.  
**inactive--not-apply**: the IP Source Guard cannot adds bound entries into filtering entries for system errors.  
**active**: the IP Source Guard is active.

**Configuration Examples** The following example displays user filtering entry of IP Source Guard.

```
Ruijie # show ip verify source
Total number of bindings: 7
```

| NO.            | INTERFACE           | FILTERTYPE    | FILTERSTATUS          | IPADDRESS     |
|----------------|---------------------|---------------|-----------------------|---------------|
| MACADDRESS     | VLAN                | TYPE          |                       |               |
| 1              | Global              | IP+MAC        | Inactive-not-apply    | 192.168.0.127 |
| 0001.0002.0003 | 1                   | Static        |                       |               |
| 2              | GigabitEthernet 0/5 | IP-ONLY       | Active                | 1.2.3.4       |
| 0001.0002.0004 | 1                   | DHCP-Snooping |                       |               |
| 3              | Global              | IP-ONLY       | Active                | 1.2.3.7       |
| 0001.0002.0007 | 1                   | Static        |                       |               |
| 4              | Global              | IP+MAC        | Active                | 1.2.3.6       |
| 0001.0002.0006 | 1                   | Static        |                       |               |
| 5              | GigabitEthernet 0/1 | UNSET         | Inactive-restrict-off | 1.2.3.9       |
| 0001.0002.0009 | 1                   | DHCP-Snooping |                       |               |
| 6              | GigabitEthernet 0/5 | IP-ONLY       | Active                | Deny-All      |

**Related

## 19 IPv6 Source Guard Commands

### 19.1 ipv6 source binding

Use this command to configure a static IPv6 source binding.

Use the **no** form of this command to delete a static IPv6 source binding.

```
ipv6 source binding mac-address vlan vlan-id ipv6-address { interface interface-id | | ip-mac | ip-only }
no ipv6 source binding mac-address vlan vlan-id ipv6-address { interface interface-id | | ip-mac |
ip-only }
```

#### Parameter Description

| Parameter           | Description        |
|---------------------|--------------------|
| <i>mac-address</i>  | MAC address        |
| <i>vlan-id</i>      | VLAN ID            |
| <i>ipv6-address</i> | IPv6 address       |
| <i>interface-id</i> | Wired interface ID |
| <b>ip-mac</b>       | IPv6-MAC binding   |
| <b>ip-only</b>      | IPv6-only binding  |

**Defaults** No static IPv6 source binding is configured by default.

**Command Mode** Global configuration mode

**Usage Guide**

- Use this command to exempt trusted hosts from IPv6 source guard.
- This command is supported only on Layer 2 ports, aggregate ports and encapsulated sub interfaces.

 A static IPv6 source binding is valid either on wired interfaces or in global configuration mode.

 A new binding will overwrite the old one sharing the same configuration.

**Configuration Examples** The following example configures static IPv6 source bindings on GigabitEthernet 0/1.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 source binding 0000.0000.0001 vlan 1 1::1 interface
GigabitEthernet 0/1
Ruijie(config)# end
```

The following example configures a static IPv6-MAC binding.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 source binding 0000.0000.0001 vlan 1 1::1 ip-mac
Ruijie(config)# end
```

The following example configures a static IPv6-only binding.

```
Ruijie# configure terminal
Ruijie(config)# ipv6 source binding 0000.0000.0001 vlan 1 1::1 ip-only
Ruijie(config)# end
```

**Platform**  
**Description**

N/A

## 19.2 ipv6 verify source

Use this command to enable IPv6 source guard.

Use the **no** form of this command to restore the default setting.

**ipv6 verify source [ port-security ]**

**no ipv6 verify source**

| Parameter Description | Parameter            | Description                        |
|-----------------------|----------------------|------------------------------------|
|                       | <b>port-security</b> | Enables source IPv6-MAC filtering. |

**Defaults** IPv6 source guard is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Use this command to enable IPv6 source guard with source IPv6 filtering or source IPv6-MAC filtering. This command is supported only on Layer 2 ports, aggregate ports and encapsulated sub interface.

 Currently, the IPv6 source guard feature of Ruijie devices filters traffic based on the DHCPv6 Snooping database or on manually configured IPv6 source bindings. A port with only IPv6 source guard enabled cannot realize normal network access for connected hosts.

**Configuration** The following example enables IPv6 source guard based on source IPv6 filtering.

### Examples

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 verify source
Ruijie(config-if)# end
```

The following example enables IPv6 source guard based on source IPv6-MAC filtering.

```
Ruijie# configure terminal
Ruijie(config)# interface GigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ipv6 verify source port-security
Ruijie(config-if)# end
```

**Platform** N/A

**Description**

## 19.3 show ipv6 source binding

Use this command to display the IPv6 source binding database.

**show ipv6 source binding** [ *ipv6-address* ] [ *mac-address* ] [ **dhcp-snooping** ] [ **static** ] [ **vlan** *vlan-id* ]  
[ **interface** *interface-id* ]

**Parameter Description**

| Parameter            | Description                                |
|----------------------|--------------------------------------------|
| <i>ipv6-address</i>  | Displays the source IPv6 address bindings. |
| <i>mac-address</i>   | Displays the source MAC address bindings.  |
| <b>dhcp-snooping</b> | Displays the DHCP snooping bindings.       |
| <b>static</b>        | Displays the static IPv6 source bindings.  |
| <i>vlan-id</i>       | Displays the VLAN bindings.                |
| <i>interface-id</i>  | Displays the interface bindings.           |

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the IPv6 source binding database.

**Examples**

```
Ruijie# show ipv6 source binding
Total number of bindings: 7
NO.      Filter Type  Filter Status      IPv6 Address
MACAddress  VLAN Type  Interface
-----
-----
-----
1        IPv6+MAC    Inactive-system-error  2000::127
0001.0002.0003  1    Static      Global
2        IPv6-ONLY   Active          2008::4
0001.0002.0004  1    DHCPv6-Snooping  GigabitEthernet 0/5
3        IPv6-ONLY   Active          2008::7
0001.0002.0007  1    Static      Global
4        IPv6+MAC    Active          2008::1
0001.0002.0006  1    Static      Global
5        UNSET       Inactive-restrict-off  2008::9
0001.0002.0009  1    DHCPv6-Snooping  GigabitEthernet 0/1
6        IPv6-ONLY   Active          Deny-All
GigabitEthernet 0/5
```

**Platform** N/A

**Description**

## 20 Anti-ARP Spoofing Commands

### 20.1 anti-arp-spoofing ip

Use this command to enable anti-ARP spoofing.

Use the **no** form of this command to disable this function.

**anti-arp-spoofing ip** *ip-address*

**no anti-arp-spoofing ip** *ip-address*

| Parameter Description | Parameter         | Description        |
|-----------------------|-------------------|--------------------|
|                       | <i>ip-address</i> | Gateway IP address |

**Defaults** The anti-ARP spoofing function is disabled by default.

**Command Mode** Interface configuration mode/Wireless security configuration mode

**Usage Guide** This command is used to enable anti-ARP spoofing on only L2 interfaces.  
This command is used on AC/AP only in wireless security configuration mode.  
Use the **show anti-arp-spoofing** command to display the configuration.

**Configuration** The following example enables anti-ARP spoofing.

**Examples**

```
Ruijie(config)#interface fastEthernet 0/1
Ruijie(config-if)#anti-arp-spoofing ip 192.168.1.1
```

| Related Commands | Command                       | Description                                   |
|------------------|-------------------------------|-----------------------------------------------|
|                  | <b>show anti-arp-spoofing</b> | Displays the anti-ARP spoofing configuration. |

**Platform** N/A

**Description**

### 20.2 show anti-arp-spoofing

Use this command to display the anti-ARP spoofing configuration on all interfaces.

**show anti-arp-spoofing**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to display the anti-ARP spoofing configuration on all interfaces.

**Configuration** The following example displays the anti-ARP-spoofing configuration on all interfaces.

**Examples**

```
Ruijie#show anti-arp-spoofing
NO      PORT      IP          STATUS
-----
1       Gi0/1      192.168.1.1  active
```

Field Description

| Field  | Description              |
|--------|--------------------------|
| NO     | Order number             |
| PORT   | Port number              |
| IP     | Gateway IP               |
| STATUS | Anti-ARP spoofing status |

**Related Commands**

| Command                     | Description                   |
|-----------------------------|-------------------------------|
| <b>anti-arp-spoofing ip</b> | Configures anti-ARP spoofing. |

**Platform Description** N/A

## 21 NFPP Commands

### 21.1 arp-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs.

Use the **no** or **default** form of this command to restore the default setting.

**arp-guard attack-threshold** { **per-src-ip** | **per-src-mac** | **per-port** } *pps*

**no arp-guard attack-threshold** { **per-src-ip** | **per-src-mac** | **per-port** }

**default arp-guard attack-threshold** { **per-src-ip** | **per-src-mac** | **per-port** }

| Parameter Description | Parameter          | Description                                                              |
|-----------------------|--------------------|--------------------------------------------------------------------------|
|                       | <b>per-src-ip</b>  | Sets the attack threshold for each source IP address.                    |
|                       | <b>per-src-mac</b> | Sets the attack threshold for each source MAC address.                   |
|                       | <b>per-port</b>    | Sets the attack threshold for each port.                                 |
|                       | <i>pps</i>         | Sets the attack threshold, in the range from 1 to 19,999 in unit of pps. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** The attack threshold shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the global attack threshold.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard attack-threshold per-src-ip 2
Ruijie(config-nfpp)# arp-guard attack-threshold per-src-mac 3
Ruijie(config-nfpp)# arp-guard attack-threshold per-port 50
```

|                  | <b>show nfpp arp-guard summary</b> | Displays the configuration.                             |
|                  | <b>show nfpp arp-guard hosts</b>   | Displays the monitored host.                            |
|                  | <b>clear nfpp arp-guard hosts</b>  | Clears the isolated host.                               |

**Platform** N/A

**Description**

## 21.2 arp-guard enable

Use this command to enable the anti-ARP guard function globally.

Use the **no** or **default** form of this command to restore the default setting.

**arp-guard enable**

**no arp-guard enable**

**default arp-guard enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** NFPP configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example enables the anti-ARP guard function globally.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard enable
```

| Related Commands | Command                            | Description                                   |
|------------------|------------------------------------|-----------------------------------------------|
|                  | <b>nfpp arp-guard enable</b>       | Enables the anti-ARP attack on the interface. |
|                  | <b>show nfpp arp-guard summary</b> | Displays the configuration.                   |

**Platform** N/A

**Description**

## 21.3 arp-guard isolate-period

Use this command to set the arp-guard isolate time globally.

Use the **no** or **default** form of this command to restore the default setting.

**arp-guard isolate-period** { *seconds* | **permanent** }

**no arp-guard isolate-period**

**default arp-guard isolate-period**

| Parameter Description | Parameter      | Description                                                                                     |
|-----------------------|----------------|-------------------------------------------------------------------------------------------------|
|                       | <i>seconds</i> | Sets the isolate time. The value is 0, or in the range from 30 to 86400 in the unit of seconds. |

|                  |                      |
|------------------|----------------------|
| <b>permanent</b> | Permanent isolation. |
|------------------|----------------------|

**Defaults** The default isolate time is 0, which means no isolation.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the arp-guard isolate time globally to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard isolate-period 180
```

**Related  
Commands**

**Description**

## 21.4 arp-guard isolate-forwarding enable

Use this command to enable packet forwarding through NFPP isolation.

Use the **no** form of this command to disable this function.

Use the **default** form of this command to restore the default setting.

**arp-guard isolate-forwarding enable**

**no arp-guard isolate-forwarding enable**

**default arp-guard isolate-forwarding enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example enables packet forwarding through NFPP isolation.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard isolate-forwarding enable
```

| Related Commands | Command | Description |

**Platform** N/A  
**Description**

## 21.5 arp-guard monitored-host-limit

Use this command to set the maximum monitored host number.

Use the **no** or **default** form of this command to restore the default setting.

**arp-guard monitored-host-limit** *number*

**no arp-guard monitored-host-limit**

**default arp-guard monitored-host-limit**

| Parameter Description | Parameter | Description   |
|-----------------------|-----------|---------------|
|                       |           | <i>number</i> |

**Defaults** The default is 20000.

**Command Mode** NFPP configuration mode

**Usage Guide** If the monitored host number has reached the default 20,000, the administrator shall set the max-number smaller than 20,000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts to remind the administrator of the invalid configuration and removing the monitored hosts.

When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_ARP\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20000 monitored hosts to remind the administrator.

**Configuration Examples** The following example sets the maximum monitored host number to 200.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard monitored-host-limit 200
```

| Related Commands | Command | Description                        |
|------------------|---------|------------------------------------|
|                  |         | <b>show nfpp arp-guard summary</b> |

**Platform** N/A  
**Description**

## 21.6 arp-guard monitor-period

Use this command to configure the arp guard monitor time.

Use the **no** or **default** form of this command to restore the default setting.

**arp-guard monitor-period** *seconds*

**no arp-guard monitor-period**

**default arp-guard monitor-period**

| Parameter Description | Parameter      | Description                                                                    |
|-----------------------|----------------|--------------------------------------------------------------------------------|
|                       | <i>seconds</i> | Sets the monitor time, in the range from 180 to 86,400 in the unit of seconds. |

**Defaults** The default is 600.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.  
If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration** The following example sets the arp guard monitor time to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard monitor-period 180
```

| Related Commands | Command                            | Description                       |

|                  | <b>show nfpp arp-guard summary</b> | Displays the configuration.       |
|                  | <b>show nfpp arp-guard hosts</b>   | Displays the monitored host list. |
|                  | <b>clear nfpp arp-guard hosts</b>  | Clears the isolated host.         |

**Platform** N/A

**Description**

## 21.7 arp-guard rate-limit

Use this command to set the arp guard rate limit.

Use the **no** or **default** form of this command to restore the default setting.

**arp-guard rate-limit** { **per-src-ip** | **per-src-mac** | **per-port** } *pps*

```
no arp-guard rate-limit { per-src-ip | per-src-mac | per-port }
default arp-guard rate-limit { per-src-ip | per-src-mac | per-port }
```

**Parameter  
Description**

| Parameter          | Description                                       |
|--------------------|---------------------------------------------------|
| <b>per-src-ip</b>  | Sets the rate limit for each source IP address.   |
| <b>per-src-mac</b> | Sets the rate limit for each source MAC address.  |
| <b>per-port</b>    | Sets the rate limit for each port.                |
| <i>pps</i>         | Sets the rate limit, in the range of 1 to 19,999. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command  
Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the arp guard rate limit.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard rate-limit per-src-ip 2
Ruijie(config-nfpp)# arp-guard rate-limit per-src-mac 3
Ruijie(config-nfpp)# arp-guard rate-limit per-port 50
```

**Related  
Commands**

Description** N/A

## 21.8 arp-guard ratelimit-forwarding enable

Use this command to set the port based arp guard rate limit.

Use the **no** form of this command to disable this function.

Use the **default** form of this command to restore the default setting.

**arp-guard ratelimit-forwarding enable**

**no arp-guard ratelimit-forwarding enable**

**default arp-guard ratelimit-forwarding enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the port based arp guard rate limit.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard ratelimit-forwarding enable
```

**Description**

## 21.9 arp-guard scan-threshold

Use this command to set the global scan threshold.

Use the **no** or **default** form of this command to restore the default setting.

**arp-guard scan-threshold** *pkt-cnt*

**no arp-guard scan-threshold**

**default arp-guard scan-threshold**

**Parameter Description**

| Parameter      | Description                                                                    |
|----------------|--------------------------------------------------------------------------------|
| <i>pkt-cnt</i> | Sets the scan threshold, in the range from 1 to 19,999 in the unit of seconds. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command Mode** NFPP configuration mode

**Usage Guide** The scanning may occur on the condition that:

- More than 15 packets are received within 10 seconds;
- The source MAC address for the link layer is constant while the source IP address is uncertain;
- The source MAC and IP address for the link layer is constant while the destination IP address is uncertain.

**Configuration** The following example sets the global scan threshold to 20pps.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# arp-guard scan-threshold 20
```

|                     | <b>show nfpp arp-guard scan</b>      | Displays the ARP guard scan table.   |
|                     | <b>clear nfpp arp-guard scan</b>     | Clears the ARP guard scan table.     |

**Platform** N/A

**Description**

## 21.10 clear nfpp arp-guard hosts

Use this command to clear the monitored host isolation.

**clear nfpp arp-guard hosts** [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* | *mac-address* ]

| Parameter<br>Description | Parameter           | Description                         |
|--------------------------|---------------------|-------------------------------------|
|                          | <i>vid</i>          | Sets the VLAN ID.                   |
|                          | <i>interface-id</i> | Sets the interface name and number. |
|                          | <i>ip-address</i>   | Sets the IP address.                |
|                          | <i>mac-address</i>  | Sets the MAC address.               |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example clears the monitored host isolation.

**Examples**

```
Ruijie# clear nfpp arp-guard hosts vlan 1 interface g0/1
```

| Related<br>Commands | Command                           | Description                                    |

**Description**

## 21.11 clear nfpp arp-guard scan

Use this command to clear ARP scanning table.

**clear nfpp arp-guard scan**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example clears ARP scanning table.

**Examples** Ruijie# clear nfpp arp-guard scan

| Related Commands | Command                           | Description                       |
|------------------|-----------------------------------|-----------------------------------|
|                  | <b>arp-guard attack-threshold</b> | Sets the global attack threshold. |
|                  | <b>nfpp arp-guard policy</b>      | Sets the attack threshold.        |
|                  | <b>show nfpp arp-guard scan</b>   | Displays the ARP scanning table.  |

**Platform** N/A

**Description**

## 21.12 clear nfpp define *name* hosts

Use this command to clear the monitored hosts. If the host is isolated, you need to release it.

**clear nfpp define *name* hosts [ vlan *vid* ] [ interface *interface-id* ] [ *ip-address* ] [ *mac-address* ] [ *ipv6-address* ]**

| Parameter Description | Parameter           | Description        |
|-----------------------|---------------------|--------------------|
|                       | <i>name</i>         | Defines guard name |
|                       | <i>vid</i>          | VLAN ID            |
|                       | <i>interface-id</i> | Interface name     |
|                       | <i>ip-address</i>   | IP address         |
|                       | <i>mac</i>          | MAC address        |

|                     |              |
|---------------------|--------------|
| <i>ipv6-address</i> | IPv6 address |
|---------------------|--------------|

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command without the parameter to clear all monitored hosts in the self-defined range.

**Configuration** The following example clears the monitored hosts.

**Examples** Ruijie# `clear nfpp define tcp hosts vlan 1 interface g 0/1`

| Related Commands | Command                             | Description                  |
|------------------|-------------------------------------|------------------------------|
|                  | <code>show nfpp define hosts</code> | Displays the isolated hosts. |

**Platform** N/A

**Description**

## 21.13 clear nfpp dhcp-guard hosts

Use this command to clear the DHCP monitored hosts, that it, release them from isolation.

**clear nfpp dhcp-guard hosts** [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *mac-address* ]

| Parameter Description | Parameter                           | Description       |
|-----------------------|-------------------------------------|-------------------|
|                       | <i>vid</i>                          | Sets the VLAN ID. |
| <i>interface-id</i>   | Sets the interface name and number. |                   |
| <i>mac-address</i>    | Sets the MAC address.               |                   |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command without the parameter to clear all monitored hosts.

**Configuration** The following example clears the DHCP monitored hosts.

**Examples** Ruijie# `clear nfpp dhcp-guard hosts vlan 1 interface g0/1`

| Related Commands | Command                                  | Description                       |
|------------------|------------------------------------------|-----------------------------------|
|                  | <code>dhcp-guard attack-threshold</code> | Sets the global attack threshold. |

|                                   |                                                |
|-----------------------------------|------------------------------------------------|
| <b>nfpp dhcp-guard policy</b>     | Sets the limit threshold and attack threshold. |
| <b>show nfpp dhcp-guard hosts</b> | Displays the monitored host.                   |

**Platform** N/A

**Description**

## 21.14 clear nfpp dhcpv6-guard hosts

Use this command to clear the DHCPv6 monitored host isolation.

**clear nfpp dhcpv6-guard hosts** [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *mac-address* ]

| Parameter Description | Parameter           | Description                         |
|-----------------------|---------------------|-------------------------------------|
|                       | <i>vid</i>          | Sets the VLAN ID.                   |
|                       | <i>interface-id</i> | Sets the interface name and number. |
|                       | <i>mac-address</i>  | Sets the MAC address.               |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command without the parameter to clear all monitored hosts

**Configuration Examples** The following example clears the DHCPv6 monitored hosts.

```
Ruijie# clear nfpp dhcpv6-guard hosts vlan 1 interface g0/1
```

| Related Commands | Command                              | Description                                    |
|------------------|--------------------------------------|------------------------------------------------|
|                  | <b>dhcpv6-guard attack-threshold</b> | Sets the global attack threshold.              |
|                  | <b>nfpp dhcpv6-guard policy</b>      | Sets the limit threshold and attack threshold. |
|                  | <b>show nfpp dhcpv6-guard hosts</b>  | Displays the monitored host.                   |

**Platform** N/A

**Description**

## 21.15 clear nfpp icmp-guard hosts

Use this command to clear the ICMP monitored hosts.

**clear nfpp icmp-guard hosts** [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* ]

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                     |                                     |
|---------------------|-------------------------------------|
| <i>vid</i>          | Sets the VLAN ID.                   |
| <i>interface-id</i> | Sets the interface name and number. |
| <i>ip-address</i>   | Sets the IP address.                |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command without the parameter to clear all monitored hosts.

**Configuration** The following example clears the ICMP monitored hosts.

**Examples** Ruijie# clear nfpp icmp-guard hosts vlan 1 interface g0/1

**Related Commands**

| Command                            | Description                                    |
|------------------------------------|------------------------------------------------|
| <b>icmp-guard attack-threshold</b> | Sets the global attack threshold.              |
| <b>nfpp icmp-guard policy</b>      | Sets the limit threshold and attack threshold. |
| <b>show nfpp icmp-guard hosts</b>  | Displays the monitored host.                   |

**Platform** N/A

**Description**

## 21.16 clear nfpp ip-guard hosts

Use this command to clear the monitored host isolation.

**clear nfpp ip-guard hosts** [ **vlan** *vid* ] [ **interface** *interface-id* ] [ *ip-address* ]

**Parameter Description**

| Parameter           | Description                         |
|---------------------|-------------------------------------|
| <i>vid</i>          | Sets the VLAN ID.                   |
| <i>interface-id</i> | Sets the interface name and number. |
| <i>ip-address</i>   | Sets the IP address.                |

**Defaults** N/A.

**Command Mode** Privileged EXEC mode

**Usage Guide** Use this command without the parameter to clear all monitored hosts.

**Configuration** The following example clears the monitored host isolation.

**Examples** Ruijie# clear nfpp ip-guard hosts vlan 1 interface g0/1

| Related<br>Commands | Command                          | Description                                    |
|---------------------|----------------------------------|------------------------------------------------|
|                     | <b>ip-guard attack-threshold</b> | Sets the global attack threshold.              |
|                     | <b>nfpp ip-guard policy</b>      | Sets the limit threshold and attack threshold. |
|                     | <b>show nfpp ip-guard hosts</b>  | Displays the monitored host.                   |

**Platform** N/A

**Description**

## 21.17 clear nfpp nd-guard hosts

Use this command to remove the speed limit on the monitored host.

**clear nfpp nd-guard hosts** [**vlan** *vid*] [**interface** *interface-id*]

| Parameter<br>Description | Parameter           | Description                         |
|--------------------------|---------------------|-------------------------------------|
|                          | <i>vid</i>          | Sets the VLAN ID.                   |
|                          | <i>interface-id</i> | Sets the interface name and number. |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** This command without any parameter is used to remove speed limit on all monitored hosts.

**Configuration  
Examples** The following example removes speed limit on interface g0/1 in VLAN 1.

```
Ruijie# clear nfpp nd-guard hosts vlan 1 interface g0/1
```

**Prompt** N/A

**Messages**

**Platform** N/A

**Description**

## 21.18 clear nfpp log

Use this command to clear the NFPP log buffer area.

**clear nfpp log**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |     |     |
|--------------------|-----|-----|
| <b>Description</b> |     |     |
|                    | N/A | N/A |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example clears the NFPP log buffer area.

**Examples** Ruijie# clear nfpp log

| <b>Related Commands</b> | Command              | Description                                                 |
|-------------------------|----------------------|-------------------------------------------------------------|
|                         | <b>show nfpp log</b> | Displays the NFPP log configuration or the log buffer area. |

**Platform** N/A

**Description**

## 21.19 define

Use this command to define the anti-attack type.

Use the **no** or **default** form of this command to restore the default setting.

**define** *name*

**no define** *name*

**default define** *name*

| <b>Parameter Description</b> | Parameter   | Description                               |
|------------------------------|-------------|-------------------------------------------|
|                              | <i>name</i> | Name of the user-defined anti-attack type |

**Defaults** N/A

**Command Mode** NFPP configuration mode

**Usage Guide** Use this command to define the anti-attack type.

**Configuration** The following example creates the user-defined anti-attack type.

**Examples** Ruijie(config)# nfpp  
 Ruijie(config-nfpp)# define tcp  
 Ruijie(config-nfpp-define)#

| Related Commands | Command | Description                     |
|------------------|---------|---------------------------------|
|                  |         | <b>show nfpp define summary</b> |

**Platform** N/A

**Description**

## 21.20 define *name* enable

Use this command to enable the user-defined anti-attack globally.

Use the **no** or **default** form of this command to restore the default setting.

**define name enable**

**no define name enable**

**default define name enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | <i>name</i> |

**Defaults** This function is disabled by default.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** This command takes effect only after the match, rate-limit and attack-threshold have been configured.

**Configuration** The following example enabled the user-defined anti-attack globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)#define tcp enable
```

| Related Commands | Command | Description                     |
|------------------|---------|---------------------------------|
|                  |         | <b>show nfpp define summary</b> |

**Platform** N/A

**Description**

## 21.21 dhcp-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs.

Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard attack-threshold { per-src-mac | per-port } pps**

**no dhcp-guard attack-threshold { per-src-mac | per-port }**

**default dhcp-guard attack-threshold { per-src-mac | per-port }**

| Parameter Description | Parameter          | Description                                                        |
|-----------------------|--------------------|--------------------------------------------------------------------|
|                       | <b>per-src-mac</b> | Sets the attack threshold for each source MAC address.             |
|                       | <b>per-port</b>    | Sets the attack threshold for each port.                           |
|                       | <i>pps</i>         | Sets the attack threshold, in pps. The valid range is 1 to 19,999. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the global attack threshold.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard attack-threshold per-src-mac 15
Ruijie(config-nfpp)# dhcp-guard attack-threshold per-port 200
```

| Related Commands | Command                             | Description                                             |
|------------------|-------------------------------------|---------------------------------------------------------|
|                  | <b>nfpp dhcp-guard policy</b>       | Displays the rate-limit threshold and attack threshold. |
|                  | <b>show nfpp dhcp-guard summary</b> | Displays the configuration.                             |
|                  | <b>show nfpp dhcp-guard hosts</b>   | Displays the monitored host list.                       |
|                  | <b>clear nfpp dhcp-guard hosts</b>  | Clears the monitored host.                              |

**Platform** N/A

**Description**

## 21.22 dhcp-guard enable

Use this command to enable the DHCP anti-attack function.

Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard enable**

**no dhcp-guard enable**

**default dhcp-guard enable**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration** The following example enables the DHCP anti-attack function.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard enable
```

| Related<br>Commands | Command | Description |
|---------------------|---------|-------------|
|                     |         | N/A         |

**Platform Description** N/A

## 21.23 dhcp-guard isolate-period

Use this command to set the isolate time globally.

Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard isolate-period** { *seconds* | **permanent** }

**no dhcp-guard isolate-period**

**default dhcp-guard isolate-period**

| Parameter<br>Description | Parameter        | Description          |
|--------------------------|------------------|----------------------|
|                          |                  | <i>seconds</i>       |
|                          | <b>permanent</b> | Permanent isolation. |

**Defaults** The default isolate time is 0, which means no isolation.

**Command Mode** NFPP configuration mode

**Usage Guide** The isolate period can be configured globally or based on the interface. For one interface, if the isolate period is not set based on the interface, the global value shall be adopted; or the interface-based isolate period shall be adopted.

**Configuration** The following example sets the isolate time globally to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard isolate-period 180
```

**Related Commands**

| Command                               | Description                             |
|---------------------------------------|-----------------------------------------|
| <b>nfpp dhcp-guard isolate-period</b> | Sets the isolate time on the interface. |
| <b>show nfpp dhcp-guard summary</b>   | Displays the configuration.             |

**Platform**

N/A

**Description**

## 21.24 dhcp-guard monitored-host-limit

Use this command to set the maximum monitored host number.

Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard monitored-host-limit** *number*

**no dhcp-guard monitored-host-limit**

**default dhcp-guard monitored-host-limit**

**Parameter Description**

| Parameter     | Description                                                              |
|---------------|--------------------------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to 4,294,967,295. |

**Defaults**

The default is 20,000.

**Command**

NFPP configuration mode

**Mode****Usage Guide**

If the monitored host number has reached the default 20,000, the administrator shall set the max-number smaller than 20,000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts to remind the administrator of the invalid configuration and removing the monitored hosts.

When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_ARP\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20000 monitored hosts to remind the administrator.

**Configuration** The following example sets the maximum monitored host number to 200.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard monitored-host-limit 200
```

**Description**

## 21.25 dhcp-guard monitor-period

Use this command to configure the monitor time.

Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard monitor-period** *seconds*

**no dhcp-guard monitor-period**

**default dhcp-guard monitor-period**

|                              |                  |                                                                                |
|------------------------------|------------------|--------------------------------------------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b> | <b>Description</b>                                                             |
|                              | <i>seconds</i>   | Sets the monitor time, in the range from 180 to 86,400 in the unit of seconds. |

**Defaults** The default is 600 seconds.

**Command Mode** NFPP configuration mode

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration Examples** The following example sets the monitor time to 180 seconds.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard monitor-period 180
```

|                         |                                     |                                   |

|                         | <b>show nfpp dhcp-guard hosts</b>   | Displays the monitored host list. |
|                         | <b>clear nfpp dhcp-guard hosts</b>  | Clears the isolated host.         |

**Platform** N/A

**Description**

## 21.26 dhcp-guard rate-limit

Use this command to set the rate-limit threshold globally.

Use the **no** or **default** form of this command to restore the default setting.

**dhcp-guard rate-limit** { per-src-mac | per-port } pps

**no dhcp-guard rate-limit** { per-src-mac | per-port }

**default dhcp-guard rate-limit** { per-src-mac | per-port }

| Parameter Description | Parameter          | Description                                       |
|-----------------------|--------------------|---------------------------------------------------|
|                       | <b>per-src-mac</b> | Sets the rate limit for each source MAC address.  |
|                       | <b>per-port</b>    | Sets the rate limit for each port.                |
|                       | <i>pps</i>         | Sets the rate limit, in the range of 1 to 19,999. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the rate-limit threshold globally.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcp-guard rate-limit per-src-mac 8
Ruijie(config-nfpp)# dhcp-guard rate-limit per-port 100
```

| Related Commands | Command                             | Description                                   |
|------------------|-------------------------------------|-----------------------------------------------|
|                  | <b>nfpp dhcp-guard policy</b>       | Sets the rate limit and the attack threshold. |
|                  | <b>show nfpp dhcp-guard summary</b> | Displays the configuration.                   |

**Platform Description** N/A

## 21.27 dhcpv6-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs.

Use the **no** or **default** form of this command to restore the default setting.

**dhcpv6-guard attack-threshold** { per-src-mac | per-port } pps

**no dhcpv6-guard attack-threshold** {per-src-mac | per-port}

**default dhcpv6-guard attack-threshold** { per-src-mac | per-port }

| Parameter Description | Parameter          | Description                                                      |
|-----------------------|--------------------|------------------------------------------------------------------|
|                       | <b>per-src-mac</b> | Sets the attack threshold for each source MAC address.           |
|                       | <b>per-port</b>    | Sets the attack threshold for each port.                         |
|                       | <i>pps</i>         | Sets the attack threshold, in the range is from 1 to 19,999 pps. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A.

**Configuration** The following example sets the global attack threshold.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcpv6-guard attack-threshold per-src-mac 15
Ruijie(config-nfpp)# dhcpv6-guard attack-threshold per-port 200
```

**Related Commands**

| Command                               | Description                                             |

## 21.29 dhcpv6-guard monitored-host-limit

Use this command to set the maximum monitored host number.

Use the **no** or **default** form of this command to restore the default setting.

**dhcpv6-guard monitored-host-limit** *number*

**no dhcpv6-guard monitored-host-limit**

**default dhcpv6-guard monitored-host-limit**

**Parameter Description**

| Parameter     | Description                                                              |
|---------------|--------------------------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to 4,294,967,295. |

**Defaults** The default is 20,000.

**Command Mode** NFPP configuration mode

**Usage Guide** If the monitored host number has reached the default 20,000, the administrator shall set the max-number smaller than 20,000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts to remind the administrator of the invalid configuration and removing the monitored hosts.

When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_DHCPV6\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20000 monitored hosts to remind the administrator.

**Configuration** The following example sets the maximum monitored host number to 200.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcpv6-guard monitored-host-limit 200
```

## 21.30 dhcpv6-guard monitor-period

Use this command to configure the monitor time.

Use the **no** or **default** form of this command to restore the default setting.

**dhcpv6-guard monitor-period** *seconds*

**no dhcpv6-guard monitor-period**

**default dhcpv6-guard monitor-period**

**Parameter  
Description**

| Parameter      | Description                                                                    |
|----------------|--------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the monitor time, in the range from 180 to 86,400 in the unit of seconds. |

**Defaults**

The default is 600 seconds.

**Command**

NFPP configuration mode

**Mode****Usage Guide**

When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration**

The following example sets the monitor time to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcpv6-guard monitor-period 180
```

|                                      |                           |
|--------------------------------------|---------------------------|
| <b>clear nfpp dhcpv6-guard hosts</b> | Clears the isolated host. |
|--------------------------------------|---------------------------|

**Platform** N/A

**Description**

## 21.31 dhcpv6-guard rate-limit

Use this command to set the rate-limit threshold globally.

Use the **no** or **default** form of this command to restore the default setting.

**dhcpv6-guard rate-limit { per-src-mac | per-port } pps**

**no dhcpv6-guard rate-limit { per-src-mac | per-port }**

**default dhcpv6-guard rate-limit { per-src-mac | per-port }**

| Parameter Description | Parameter          | Description                                         |
|-----------------------|--------------------|-----------------------------------------------------|
|                       | <b>per-src-mac</b> | Sets the rate limit for each source MAC address.    |
|                       | <b>per-port</b>    | Sets the rate limit for each port.                  |
|                       | <i>pps</i>         | Sets the rate limit, in the range from 1 to 19,999. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the rate-limit threshold globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# dhcpv6-guard rate-limit per-src-mac 8
Ruijie(config-nfpp)# dhcpv6-guard rate-limit per-port 100
```

| Related Commands | Command                               | Description                                   |
|------------------|---------------------------------------|-----------------------------------------------|
|                  | <b>nfpp dhcpv6-guard policy</b>       | Sets the rate limit and the attack threshold. |
|                  | <b>show nfpp dhcpv6-guard summary</b> | Displays the configuration.                   |

**Platform** N/A

**Description**

## 21.32 global-policy

Use this command to set the rate-limit threshold and attack threshold based on the host or port.

Use the **no** or **default** form of this command to restore the default setting.

**global-policy** { **per-src-mac** | **per-src-ip** | **per-port** } *rate-limit-pps* *attack-threshold-pps*

**no global-policy** { **per-src-mac** | **per-src-ip** | **per-port** }

**default global-policy** { **per-src-mac** | **per-src-ip** | **per-port** }

**Parameter  
Description**

| Parameter                   | Description                                                                        |
|-----------------------------|------------------------------------------------------------------------------------|
| <b>per-src-ip</b>           | Performs the rate statistics based on the source IP / VID and port.                |
| <b>per-src-mac</b>          | Performs the rate statistics based on the source MAC / VID and port.               |
| <b>per-port</b>             | Performs the rate statistics based on each physical port of receiving the packets. |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold.                                                     |
| <i>attack-threshold-pps</i> | Sets the attack threshold.                                                         |

**Defaults**

By default, no rate-limit threshold and attack threshold is configured. To enable self-defined anti-attack, these two parameters must be set.

**Command**

NFPP define configuration mode

**Mode**

**Usage Guide**

To create a user-defined anti-attack type, the classification rule for the rate statistics must be specified, that is, recognize the host based on the source IP address/ source MAC address for the user-defined packets rate statistics based on the user / port and specify the rate-limit threshold and attack threshold for each classification. The rate-limit threshold shall be equal to or greater than the attack threshold. If the rate is greater than the rate-limit threshold, the packets that meet this classification rule will be discarded. If the rate exceeds the attack threshold, the user will be regarded as an attacker. The log will be printed and the trap will be sent.

**Configuration**

The following example sets the rate-limit threshold and attack threshold based on the host or port.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nfpp define tcp
Ruijie(config-nfpp-define)# global-policy per-src-ip 10 20
Ruijie(config-nfpp-define)# global-policy per-port 100 200
```

**Related  
Commands**

|----------------------------------------------|-----------------------------------------------------|
| <b>nfpp define</b> <i>name</i> <b>policy</b> | Sets the rate-limit threshold and attack threshold. |
| <b>show nfpp define summary</b>              | Displays the user-defined anti-attack configuration |

**Platform**

N/A

**Description**

## 21.33 icmp-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs.

Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard attack-threshold** { **per-src-ip** | **per-port** } *pps*

**no icmp-guard attack-threshold** { **per-src-ip** | **per-port** }

**default icmp-guard attack-threshold** { **per-src-ip** | **per-port** }

| Parameter Description | Parameter         | Description                                                                  |
|-----------------------|-------------------|------------------------------------------------------------------------------|
|                       | <b>per-src-ip</b> | Sets the attack threshold for each source IP address.                        |
|                       | <b>per-port</b>   | Sets the attack threshold for each port.                                     |
|                       | <i>pps</i>        | Sets the attack threshold, in the range from 1 to 19,999 in the unit of pps. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the global attack threshold.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard attack-threshold per-src-ip 600
Ruijie(config-nfpp)# icmp-guard attack-threshold per-port 1200
```

| Related Commands | Command                             | Description                                             |
|------------------|-------------------------------------|---------------------------------------------------------|
|                  | <b>nfpp icmp-guard policy</b>       | Displays the rate-limit threshold and attack threshold. |
|                  | <b>show nfpp icmp-guard summary</b> | Displays the configuration.                             |
|                  | <b>show nfpp icmp-guard hosts</b>   | Displays the monitored host list.                       |
|                  | <b>clear nfpp icmp-guard hosts</b>  | Clears the monitored host.                              |

**Platform Description** N/A

## 21.34 icmp-guard enable

Use this command to enable the ICMP anti-attack function.

Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard enable**

**no icmp-guard enable**

**default icmp-guard enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example enables the ICMP anti-attack function globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard enable
```

| Related Commands | Command                             | Description                                             |
|------------------|-------------------------------------|---------------------------------------------------------|
|                  | <b>nfpp icmp-guard enable</b>       | Enables the ICMP anti-attack function on the interface. |
|                  | <b>show nfpp icmp-guard summary</b> | Displays the configuration.                             |

**Platform** N/A

**Description**

## 21.35 icmp-guard isolate-period

Use this command to set the isolate time globally.

Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard isolate-period** { *seconds* | **permanent** }

**no icmp-guard isolate-period**

**default icmp-guard isolate-period**

| Parameter Description | Parameter        | Description                                                                                        |
|-----------------------|------------------|----------------------------------------------------------------------------------------------------|
|                       | <i>seconds</i>   | Sets the isolate time. The value is in the range is 0 or from 30 to 86,400 in the unit of seconds. |
|                       | <b>permanent</b> | Permanent isolation.                                                                               |

**Defaults** The default isolate time is 0, which means no isolation.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** The isolate period can be configured globally or based on the interface. For one interface, if the isolate period is not set based on the interface, the global value shall be adopted; or the interface-based isolate period shall be adopted.

**Configuration** The following example sets the isolate time globally to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard isolate-period 180
```

**Related  
Commands**

| Command                               | Description                             |
|---------------------------------------|-----------------------------------------|
| <b>nfpp icmp-guard isolate-period</b> | Sets the isolate time on the interface. |
| <b>show nfpp icmp-guard summary</b>   | Displays the configuration.             |

**Platform** N/A

**Description**

## 21.36 icmp-guard monitored-host-limit

Use this command to set the maximum monitored host number.

Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard monitored-host-limit** *number*

**no icmp-guard monitored-host-limit**

**default icmp-guard monitored-host-limit**

**Parameter  
Description**

| Parameter     | Description                                                              |
|---------------|--------------------------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to 4,294,967,295. |

**Defaults** The default is 20,000.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** If the monitored host number has reached the default 20,000, the administrator shall set the max-number smaller than 20,000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts to remind the administrator of the invalid configuration and removing the monitored hosts.

When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_ARP\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20,000 monitored hosts to

remind the administrator.

**Configuration** The following example sets the maximum monitored host number to 200.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard monitored-host-limit 200
```

**Related  
Commands**

| Command                             | Description                 |
|-------------------------------------|-----------------------------|
| <b>show nfpp icmp-guard summary</b> | Displays the configuration. |

**Platform** N/A

**Description**

## 21.37 icmp-guard monitor-period

Use this command to configure the monitor time.

Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard monitor-period** *seconds*

**no icmp-guard monitor-period**

**default icmp-guard monitor-period**

**Parameter  
Description**

| Parameter      | Description                                                     |
|----------------|-----------------------------------------------------------------|
| <i>seconds</i> | Sets the monitor time, in the range from 180 to 86,400 seconds. |

**Defaults** The default is 600.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration** The following example sets the monitor time to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard monitor-period 180
```

**Related  
Commands**

| <b>show nfpp icmp-guard hosts</b>  | Displays the monitored host list. |
| <b>clear nfpp icmp-guard hosts</b> | Clears the isolated host.         |

**Platform** N/A

**Description**

## 21.38 icmp-guard rate-limit

Use this command to set the rate-limit threshold globally.

Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard rate-limit { per-src-ip | per-port } pps**

**no icmp-guard rate-limit { per-src-ip | per-port }**

**default icmp-guard rate-limit { per-src-ip | per-port }**

| Parameter<br>Description | Parameter       | Description                                         |
|--------------------------|-----------------|-----------------------------------------------------|
|                          |                 | <b>per-src-ip</b>                                   |
|                          | <b>per-port</b> | Sets the rate limit for each port.                  |
|                          | <i>pps</i>      | Sets the rate limit, in the range from 1 to 19,999. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the rate-limit threshold globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard rate-limit per-src-ip 500
Ruijie(config-nfpp)# icmp-guard rate-limit per-port 800
```

| Related<br>Commands | Command                             | Description                   |

|                     |                                     | <b>nfpp icmp-guard policy</b> |
|                     | <b>show nfpp icmp-guard summary</b> | Displays the configuration.   |

**Platform** N/A

**Description**

## 21.39 icmp-guard trusted-host

Use this command to set the trusted hosts free from monitoring.

Use the **no** or **default** form of this command to restore the default setting.

**icmp-guard trusted-host** *ip mask*

**no icmp-guard trusted-host** { **all** | *ip mask* }

**default icmp-guard trusted-host**

| Parameter Description | Parameter   | Description                                     |
|-----------------------|-------------|-------------------------------------------------|
|                       | <i>ip</i>   | Sets the IP address.                            |
|                       | <i>mask</i> | Sets the IP mask.                               |
|                       | <b>all</b>  | Deletes the configuration of all trusted hosts. |

**Defaults** No trusted host is configured by default.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** The administrator can use this command to set the trusted host free from monitoring. The ICMP packets are allowed to send to the trusted host CPU without any rate-limit and warning configuration. Configure the mask to set all hosts in one network segment free from monitoring. UP to 500 trusted hosts are supported.

**Configuration** The following example sets the trusted hosts free from monitoring.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# icmp-guard trusted-host 1.1.1.0 255.255.255.0
```

|                  | <b>show nfpp icmp-guard trusted-host</b> | Displays the configuration. |

**Platform** N/A

**Description**

## 21.40 ip-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs.

Use the **no** or **default** form of this command to restore the default setting.

**ip-guard attack-threshold** { **per-src-ip** | **per-port** } *pps*

**no ip-guard attack-threshold** { **per-src-ip** | **per-port** }

**default ip-guard attack-threshold** { **per-src-ip** | **per-port** }

| Parameter Description | Parameter         | Description                                                        |
|-----------------------|-------------------|--------------------------------------------------------------------|
|                       | <b>per-src-ip</b> | Sets the attack threshold for each source IP address.              |
|                       | <b>per-port</b>   | Sets the attack threshold for each port.                           |
|                       | <i>pps</i>        | Sets the attack threshold, in pps. The valid range is 1 to 19,999. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command Mode** NFPP configuration mode

**Usage Guide** The attack threshold shall be equal to or larger than the rate-limit threshold.

**Configuration** The following example sets the global attack threshold.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard attack-threshold per-src-ip 2
Ruijie(config-nfpp)# ip-guard attack-threshold per-port 50
```

| Related Commands | Command                           | Description                                             |
|------------------|-----------------------------------|---------------------------------------------------------|
|                  | <b>nfpp ip-guard policy</b>       | Displays the rate-limit threshold and attack threshold. |
|                  | <b>show nfpp ip-guard summary</b> | Displays the configuration.                             |
|                  | <b>show nfpp ip-guard hosts</b>   | Displays the monitored host list.                       |
|                  | <b>clear nfpp ip-guard hosts</b>  | Clears the monitored host.                              |

**Platform** N/A  
**Description**

## 21.41 ip-guard enable

Use this command to enable IP guard.

Use the **no** or **default** form of this command to restore the default setting.

**ip-guard enable**

**no ip-guard enable**

**default ip-guard enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

- Defaults** This function is enabled by default.
- Command** NFPP configuration mode.
- Mode**
- Usage Guide** This configuration aims at attacks whose destination IP address is not the local one. For those with the local address as the destination, CPP (CPU Protect Policy) will limit their rates.

**Configuration** The following example enables the IP guard globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard enable
```

| Related Commands | Command | Description                 |
|------------------|---------|-----------------------------|
|                  |         | <b>nfpp ip-guard enable</b> |

**Platform** N/A

**Description**

## 21.42 ip-guard isolate-period

Use this command to set the isolate time globally.

Use the **no** or **default** form of this command to restore the default setting.

**ip-guard isolate-period** { *seconds* | **permanent** }

**no ip-guard isolate-period**

**default ip-guard isolate-period**

| Parameter Description | Parameter        | Description         |
|-----------------------|------------------|---------------------|
|                       |                  | <i>seconds</i>      |
|                       | <b>permanent</b> | Permanent isolation |

**Defaults** The default isolate time is 0 second, which means no isolation.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A.

**Configuration** The following example sets the isolate time globally to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard isolate-period 180
```

| Related Commands | Command                             | Description                             |
|------------------|-------------------------------------|-----------------------------------------|
|                  | <b>nfpp ip-guard isolate-period</b> | Sets the isolate time on the interface. |
|                  | <b>show nfpp ip-guard summary</b>   | Displays the configuration.             |

**Platform** N/A

**Description**

## 21.43 ip-guard monitor-period

Use this command to configure the monitor time.

Use the **no** or **default** form of this command to restore the default setting.

**ip-guard monitor-period** *seconds*

**no ip-guard monitor-period**

**default ip-guard monitor-period**

| Parameter Description | Parameter      | Description |
|-----------------------|----------------|-------------|
|                       | <i>seconds</i> |             |

**Defaults** The default is 600 seconds.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0.

If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software

**Configuration** The following example sets the monitor time to 180 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard monitor-period 180
```

| Related Commands | Command                           | Description                       |

|                  | <b>show nfpp ip-guard summary</b> | Displays the configuration.       |
|                  | <b>show nfpp ip-guard hosts</b>   | Displays the monitored host list. |
|                  | <b>clear nfpp ip-guard hosts</b>  | Clears the isolated host.         |

**Platform** N/A

**Description**

## 21.44 ip-guard monitored-host-limit

Use this command to set the maximum monitored host number.

Use the **no** or **default** form of this command to restore the default setting.

**ip-guard monitored-host-limit** *number*

**no ip-guard monitored-host-limit**

**default ip-guard monitored-host-limit**

**Parameter  
Description**

| Parameter     | Description                                                              |
|---------------|--------------------------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to 4,294,967,295. |

**Defaults** The default is 20,000 seconds.

**Command  
Mode** NFPP configuration mode

**Usage Guide** If the monitored host number has reached the default 20,000, the administrator shall set the max-number smaller than 20,000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts to remind the administrator of the invalid configuration and removing the monitored hosts.

When the maximum monitored host number has been exceeded, it prompts the message that %NFPP\_ARP\_GUARD-4-SESSION\_LIMIT: Attempt to exceed limit of 20,000 monitored hosts to remind the administrator.

**Configuration** The following example sets the maximum monitored host number to 200.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard monitored-host-limit 200
```

**Description**

## 21.45 ip-guard rate-limit

Use this command to set the rate-limit threshold globally.

Use the **no** or **default** form of this command to restore the default setting.

**ip-guard rate-limit** { **per-src-ip** | **per-port** } *pps*

**no ip-guard rate-limit** { **per-src-ip** | **per-port** }

**default ip-guard rate-limit** {**per-src-ip** | **per-port** }

| Parameter Description | Parameter         | Description                                       |
|-----------------------|-------------------|---------------------------------------------------|
|                       | <b>per-src-ip</b> | Sets the rate limit for each source IP address.   |
|                       | <b>per-port</b>   | Sets the rate limit for each port.                |
|                       | <i>pps</i>        | Sets the rate limit, in the range of 1 to 19,999. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the rate-limit threshold globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard rate-limit per-src-ip 2
Ruijie(config-nfpp)# ip-guard rate-limit per-port 50
```

| Related Commands | Command                           | Description                                   |
|------------------|-----------------------------------|-----------------------------------------------|
|                  | <b>nfpp ip-guard policy</b>       | Sets the rate limit and the attack threshold. |
|                  | <b>show nfpp ip-guard summary</b> | Displays the configuration.                   |

**Platform** N/A

**Description**

## 21.46 ip-guard scan-threshold

Use this command to set the global scan threshold.

Use the **no** or **default** form of this command to restore the default setting.

**ip-guard scan-threshold** *pkt-cnt*

**no ip-guard scan-threshold**

**default ip-guard scan-threshold**

| Parameter Description | Parameter      | Description                                             |
|-----------------------|----------------|---------------------------------------------------------|
|                       | <i>pkt-cnt</i> | Sets the scan threshold, in the range from 1 to 19,999. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the global scan threshold to 20 pps.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard scan-threshold 20
```

**Related  
Commands**

| Command                             | Description                          |
|-------------------------------------|--------------------------------------|
| <b>nfpp ip-guard scan-threshold</b> | Sets the scan threshold on the port. |
| <b>show nfpp ip-guard summary</b>   | Displays the configuration.          |

**Platform** N/A

**Description**

## 21.47 ip-guard trusted-host

Use this command to set the trusted hosts free form monitoring.

Use the **no** or **default** form of this command to restore the default setting.

**ip-guard trusted-host** *ip mask*

**no ip-guard trusted-host** { **all** | *ip mask* }

**default ip-guard trusted-host**

**Parameter  
Description**

| Parameter   | Description                                     |
|-------------|-------------------------------------------------|
| <i>ip</i>   | Sets the IP address.                            |
| <i>mask</i> | Sets the IP mask.                               |
| <b>all</b>  | Deletes the configuration of all trusted hosts. |

**Defaults** N/A

**Command** NFPP configuration mode

**Mode**

**Usage Guide** The administrator can use this command to set the trusted host free from monitoring. The ICMP packets are allowed to sent to the trusted host CPU without any rate-limit and warning configuration. Configure the mask to set all hosts in one network segment free from monitoring. UP to 500 trusted hosts are supported.

**Configuration** The following example sets the trusted hosts free form monitoring.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# ip-guard trusted-host 1.1.1.0 255.255.255.0
```

**Related

**Description**

## 21.48 log-buffer enable

Use this command to display logs on the screen.

Use the **no** or the **default** form of this command to restore the default setting.

**log-buffer enable**

**no log-buffer enable**

**default log-buffer enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** Logs are stored in the cache by default.

**Command  
Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration** The following example displays logs on the screen.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# log-buffer enable
```

**Related  
Commands**

**Description**

## 21.49 log-buffer entries

Use this command to set the NFPP log buffer area size.

Use the **no** or **default** form of this command to restore the default setting.

**log-buffer entries** *number*

**no log-buffer entries**

**default log-buffer entries**

| Parameter Description | Parameter     | Description                                         |
|-----------------------|---------------|-----------------------------------------------------|
|                       | <i>number</i> | The buffer area size, in the range from 0 to 1,024. |

**Defaults** The default is 256.

**Command Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the NFPP log buffer area size.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# log-buffer entries 50
```

| Related Commands | Command                                                                    | Description                                                          |

**Platform** N/A

**Description**

## 21.50 log-buffer logs

Use this command to set the rate of syslog generated from the NFPP log buffer area.

Use the **no** or **default** form of this command to restore the default setting.

**log-buffer logs** *number\_of\_message interval length\_in\_seconds*

**no log-buffer logs**

**default log-buffer logs**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>number_of_message</i> | The valid range is from 0 to 1024.<br>0 indicates that all logs are recorded in the specific buffer area and no syslogs are generated.                                                                                                                                                                                                                                                                                                                    |
| <i>length_in_seconds</i> | The valid range is from 0 to 86400(one day).<br>0 indicates not to write the log to the buffer area but generate the syslog immediately.<br>With both the <i>number_of_message</i> and <i>length_in_seconds</i> values are 0, it indicates not to write the log to the buffer area but generate the syslog immediately.<br>The parameter <i>number_of_message /length_in_second</i> indicates the rate of syslog generated from the NFPP log buffer area. |

**Defaults** By default, *number\_of\_message* is 0 and *length\_in\_seconds* is 0.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the rate of syslog generated from the NFPP log buffer area.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# log-buffer logs 2 interval 12
```

**Related  
Commands**

| Command                                 | Description                                                 |
|-----------------------------------------|-------------------------------------------------------------|
| <b>log-buffer entries</b> <i>number</i> | Sets the NFPP log buffer area size.                         |
| <b>show nfpp log summary</b>            | Displays the NFPP log configuration or the log buffer area. |

**Platform** N/A

**Description**

## 21.51 logging

Use this command to set the VLAN or the interface log for NFPP.

Use the **no** or **default** form of this command to restore the default setting.

**logging vlan** *vlan-range*

**logging interface** *interface-id*

**no logging vlan** *vlan-range*

**no logging interface** *interface-id*

**default logging**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                     |                                                                |
|---------------------|----------------------------------------------------------------|
| <i>vlan-range</i>   | Sets the specified VLAN range, in the format such as "1-3, 5". |
| <i>interface-id</i> | Sets the interface ID.                                         |

**Defaults** All logs are recorded by default.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** Use this command to filter the logs and records the logs within the specified VLAN range or the specified port

**Configuration** The following example records the logs in VLAN 1, VLAN 2, VLAN 3 and VLAN 5 only.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# logging vlan 1-3,5
```

The following example records the logs on the interface GigabitEthernet 0/1 only.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# logging interface G 0/1
```

**Related  
Commands**

| Command                      | Description                                                 |
|------------------------------|-------------------------------------------------------------|
| <b>show nfpp log summary</b> | Displays the NFPP log configuration or the log buffer area. |

**Platform** N/A

**Description**

## 21.52 match

Use this command to specify the message matching filed for the user-defined anti-attack.

```
match [ etype type ] [ src-mac smac [ src-mac-mask smac_mask ] ] [ dst-mac dmac
[ dst-mac-mask dst_mask ] ] [ protocol protocol ] [ src-ip sip [ src-ip-mask sip-mask ] ] [ src-ipv6
sipv6 [ src-ipv6-masklen sipv6-masklen ] ] [ dst-ip dip [ dst-ip-mask dip-mask ] ] [ dst-ipv6 dipv6
[ dst-ipv6-masklen dipv6-masklen ] ] [ src-port sport ] [ dst-port dport ]
```

**Parameter  
Description**

| Parameter        | Description                     |
|------------------|---------------------------------|
| <i>type</i>      | Ethernet link layer packet type |
| <i>smac</i>      | Source MAC address              |
| <i>smac_mask</i> | Source MAC address mask         |
| <i>dmac</i>      | Destination MAC address         |
| <i>dmac_mask</i> | Destination MAC address mask    |
| <i>protocol</i>  | IPv4/v6 message protocol        |

|                     |                                              |
|---------------------|----------------------------------------------|
| <i>sip</i>          | Source IPv4 address                          |
| <i>sip_mask</i>     | Source IPv4 address mask                     |
| <i>sip6</i>         | Source IPv6 address                          |
| <i>sip6_masklen</i> | Source IPv6 address mask                     |
| <i>dip</i>          | Destination IPv4 address                     |
| <i>dip_mask</i>     | Destination IPv4 address mask                |
| <i>dip6</i>         | Destination IPv6 address                     |
| <i>dip6_masklen</i> | Length of the destination IPv6 address mask. |
| <i>sport</i>        | Source port                                  |
| <i>dport</i>        | Destination port                             |

**Defaults** N/A

**Command** NFPP configuration mode

**Mode**

**Usage Guide** Use this command to create a new user-defined anti-attack type and specify the message fields to be matched.

**Configuration** The following example specifies the message matching filed for the user-defined anti-attack.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nfpp define tcp
Ruijie(config-nfpp-define)#match etype 0x0800 protocol 0x06
```

## 21.53 monitored-host-limit

Use this command to set the maximum monitored host number.

Use the **no** or **default** form of this command to restore the default setting.

**monitored-host-limit** *number*

**no monitored-host-limit**

**default monitored-host-limit**

**Parameter  
Description**

| Parameter     | Description                                               |
|---------------|-----------------------------------------------------------|
| <i>number</i> | The maximum monitored host number, in the range from 1 to |

|  |                |
|--|----------------|
|  | 4,294,967,295. |
|--|----------------|

**Defaults** The default is 20,000.

**Command Mode** NFPP define configuration mode

**Usage Guide** If the monitored host number has reached the default 20,000, the administrator shall set the max-number smaller than 20,000 and it will prompt the message that %ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts to remind the administrator of the invalid configuration and removing the monitored hosts.  
When the maximum monitored host number has been exceeded, it prompts the message that % %NFPP\_DEFINE-4-SESSION\_LIMIT: Attempt to exceed limit of name's 20,000 monitored hosts. to remind the administrator

**Configuration** The following example sets the maximum monitored host number.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nfpp define tcp
Ruijie(config-nfpp-define)#monitored-host-limit 500
```

**Description**

## 21.54 monitor period

Use this command to set the monitoring time.

Use the **no** or **default** form of this command to restore the default setting.

**monitor-period** *seconds*

**no monitor-period**

**default monitor-period**

**Parameter Description**

| Parameter      | Description                                                                    |
|----------------|--------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the monitor time, in the range from 180 to 86,400 in the unit of seconds. |

**Defaults** The default is 600 seconds.

**Command** NFPP define configuration mode

**Mode**

**Usage Guide** When the attacker is detected, if the isolate period is 0, the attacker will be monitored by the software and the timeout time will be the monitor period. During the software monitoring, if the isolate period is not 0, the software-monitored attacker will be auto-isolated by the hardware and the timeout time will be the isolate period. The monitor period is valid with the isolate period 0. If the isolate period has changed to be 0, the attackers on the interface will be removed rather than being monitored by the software.

**Configuration** The following example sets the monitoring time to 1,000 seconds.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# define tcp
Ruijie(config-nfpp-define)#monitor-period 1000
```

| <b>show nfpp define summary</b> | Displays the user-defined anti-attack configuration. |

**Platform** N/A

**Description**

## 21.55 nd-guard attack-threshold

Use this command to set the global attack threshold. When the packet rate exceeds the attack threshold, the attack occurs.

Use the **no** or **default** form of this command to restore the default setting.

**nd-guard attack-threshold per-port { ns-na | rs | ra-redirect } pps**

**no nd-guard attack-threshold per-port { ns-na | rs | ra-redirect }**

**default nd-guard attack-threshold per-port { ns-na | rs | ra-redirect }**

**Parameter Description**

| Parameter          | Description                                                                     |
|--------------------|---------------------------------------------------------------------------------|
| <b>ns-na</b>       | Sets the neighbor request and neighbor advertisement.                           |
| <b>rs</b>          | Sets the router request.                                                        |
| <b>ra-redirect</b> | Sets the router advertisement and the redirect packets.                         |
| <i>pps</i>         | Sets the attack threshold, in the range from 1 to 19999 in the unit of seconds. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode.

**Mode**

**Usage Guide** The attack threshold shall be equal to or larger than the rate-limit threshold.

**Configuration** The following example sets the global attack threshold.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nd-guard attack-threshold per-port ns-na 20
Ruijie(config-nfpp)# nd-guard attack-threshold per-port rs 10
Ruijie(config-nfpp)# nd-guard attack-threshold per-port ra-redirect 10
```

**Related  
Commands**

| <b>nfpp ip-guard policy</b>       | Displays the rate-limit threshold and attack threshold. |
| <b>show nfpp ip-guard summary</b> | Displays the configuration.                             |

**Platform** N/A

**Description**

## 21.56 nd-guard enable

Use this command to enable the ND anti-attack function.

Use the **no** or **default** form of this command to restore the default setting.

**nd-guard enable**

**no nd-guard enable**

**default nd-guard enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example enables the ND anti-attack function.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nd-guard enable
```

**Related  
Commands**

| Command                     | Description                                           |
|-----------------------------|-------------------------------------------------------|
| <b>nfpp nd-guard enable</b> | Enables the ND anti-attack function on the interface. |

|                                   |                             |

**Description**

## 21.57 nd-guard rate-limit

Use this command to set the rate-limit threshold globally.

Use the **no** or **default** form of this command to restore the default setting.

**nd-guard rate-limit per-port { ns-na | rs | ra-redirect } pps**

**no nd-guard rate-limit per-port { ns-na | rs | ra-redirect }**

**default nd-guard rate-limit per-port { ns-na | rs | ra-redirect }**

**Parameter  
Description**

| Parameter          | Description                                                                     |
|--------------------|---------------------------------------------------------------------------------|
| <b>ns-na</b>       | Sets the neighbor request and neighbor advertisement.                           |
| <b>rs</b>          | Sets the router request.                                                        |
| <b>ra-redirect</b> | Sets the router advertisement and the redirect packets.                         |
| <i>pps</i>         | Sets the attack threshold, in the range is from 1 to 19,999 in the unit of pps. |

**Defaults** The default value varies with products. For details, see the *Configuration Guide*.

**Command** NFPP configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the rate-limit threshold globally.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nd-guard rate-limit per-port ns-na 10
Ruijie(config-nfpp)# nd-guard rate-limit per-port rs 5
Ruijie(config-nfpp)# nd-guard rate-limit per-port ra-redirect 5
```

**Related  
Commands**

| Command                           | Description                                   |
|-----------------------------------|-----------------------------------------------|
| <b>nfpp nd-guard policy</b>       | Sets the rate limit and the attack threshold. |
| <b>show nfpp nd-guard summary</b> | Displays the configuration.                   |

**Platform** N/A

**Description**

## 21.58 nd-guard ratelimit-forwarding enable

Use this command to enable the ND-guard ratelimit-forwarding on the interface.

**nd-guard ratelimit-forwarding enable**

Use this command to disable the ND-guard ratelimit-forwarding on the interface.

**no nd-guard ratelimit-forwarding enable**

Use this command to restore the default setting.

**default nd-guard ratelimit-forwarding enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The function is enabled by default.

**Command Mode** NFPP configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables the ND-guard ratelimit-forwarding on the interface.

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# nd-guard ratelimit-forwarding enable
```

**Platform Description** N/A

## 21.59 nfpp

Use this command to enter NFPP configuration mode.

**nfpp**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** Use this command to enter NFPP configuration mode and make further configuration.

**Configuration** The following example enters NFPP configuration mode.

**Examples**

```
Ruijie(config)# nfpp
```

**Platform** N/A

**Description**

## 21.60 nfpp arp-guard enable

Use this command to enable the anti-ARP attack function on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp arp-guard enable**

**no nfpp arp-guard enable**

**default nfpp arp-guard enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The anti-ARP attack function is not enabled on the interface.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The interface anti-ARP attack configuration is prior to the global configuration.

**Configuration** The following example enables the anti-ARP attack function on the interface.

**Examples**

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp arp-guard enable
```

**Related  
Commands**

| Command                            | Description                           |
|------------------------------------|---------------------------------------|
| <b>arp-guard enable</b>            | Enables the anti-ARP attack function. |
| <b>show nfpp arp-guard summary</b> | Displays the configuration.           |

**Platform** N/A

**Description**

## 21.61 nfpp arp-guard isolate-period

Use this command to set the isolate period in the interface configuration mode.

Use the **no** or **default** form of this command to restore the default setting.

```

nfpp arp-guard isolate-period { seconds | permanent }
no nfpp arp-guard isolate-period
default nfpp arp-guard isolate-period

```

| Parameter Description | Parameter        | Description                                                                                        |
|-----------------------|------------------|----------------------------------------------------------------------------------------------------|
|                       | <i>seconds</i>   | Sets the isolate period. The value is 0, or in the range from 30 to 86,400 in the unit of seconds. |
|                       | <b>permanent</b> | Permanent isolation                                                                                |

**Defaults** By default, the isolate period is not configured.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the isolate period in the interface configuration mode.

```

Examples Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp arp-guard isolate-period 180

```

| Related Commands | Command                            | Description                     |
|------------------|------------------------------------|---------------------------------|
|                  | <b>arp-guard isolate-period</b>    | Sets the global isolate period. |
|                  | <b>show nfpp arp-guard summary</b> | Displays the configuration.     |

**Platform Description** N/A

## 21.62 nfpp arp-guard policy

Use this command to set the rate-limit threshold and the attack threshold.

Use the **no** or **default** form of this command to restore the default setting.

```

nfpp arp-guard policy { per-src-ip | per-src-mac | per-port } rate-limit-pps attack-threshold-pps
no nfpp arp-guard policy { per-src-ip | per-src-mac | per-port }
default nfpp arp-guard policy { per-src-ip | per-src-mac | per-port }

```

| Parameter Description | Parameter          | Description                                                                         |
|-----------------------|--------------------|-------------------------------------------------------------------------------------|
|                       | <b>per-src-ip</b>  | Sets the rate-limit threshold and the attack threshold for each source IP address.  |
|                       | <b>per-src-mac</b> | Sets the rate-limit threshold and the attack threshold for each source MAC address. |

|                             |                                                                       |
|-----------------------------|-----------------------------------------------------------------------|
| <b>per-port</b>             | Sets the rate-limit threshold and the attack threshold for each port. |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range from 1 to 19999.          |
| <i>attack-threshold-pps</i> | Sets the attack threshold, in the range from 1 to 19999.              |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp arp-guard policy per-src-ip 2 10
Ruijie(config-if)# nfpp arp-guard policy per-src-mac 3 10
Ruijie(config-if)# nfpp arp-guard policy per-port 50 100
```

**Related  
Commands**

| Command                            | Description                           |
|------------------------------------|---------------------------------------|
| <b>arp-guard attack-threshold</b>  | Sets the global attack threshold.     |
| <b>arp-guard rate-limit</b>        | Sets the global rate-limit threshold. |
| <b>show nfpp arp-guard summary</b> | Displays the configuration.           |
| <b>show nfpp arp-guard hosts</b>   | Displays the monitored host.          |
| <b>clear nfpp arp-guard hosts</b>  | Clears the isolated host.             |

**Platform** N/A

**Description**

## 21.63 nfpp arp-guard scan-threshold

Use this command to set the scan threshold.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp arp-guard scan-threshold** *pkt-cnt*

**no nfpp arp-guard scan-threshold**

**default nfpp arp-guard scan-threshold**

**Parameter  
Description**

| Parameter      | Description                                             |
|----------------|---------------------------------------------------------|
| <i>pkt-cnt</i> | Sets the scan threshold, in the range from 1 to 19,999. |

**Defaults** By default, the sport-based scan threshold is not configured.

**Command** Interface configuration mode

**Mode****Usage Guide** N/A**Configuration** The following example sets the scan threshold to 20 pps.**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp arp-guard scan-threshold 20
```

**Related  
Commands**

| Command                            | Description                       |
|------------------------------------|-----------------------------------|
| <b>arp-guard attack-threshold</b>  | Sets the global attack threshold. |
| <b>show nfpp arp-guard summary</b> | Displays the configuration.       |
| <b>show nfpp arp-guard scan</b>    | Displays the ARP scan table.      |
| <b>clear nfpp arp-guard scan</b>   | Clears the ARP scan table.        |

**Platform** N/A**Description**

## 21.64 nfpp define *name* enable

Use this command to enable the user-defined anti-attack function on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp define *name* enable**

**no nfpp define *name* enable**

**default nfpp define *name* enable**

**Parameter  
Description**

| Parameter   | Description                               |
|-------------|-------------------------------------------|
| <i>name</i> | Name of the user-defined anti-attack type |

**Defaults** N/A**Command** Interface configuration mode.**Mode****Usage Guide** This command takes effect only after the name of the user-defined anti-attack and the match, rate-count, rate-limit and the attack-threshold have been configured.**Configuration** The following example enables the user-defined anti-attack function on the interface.**Examples**

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp define tcp enable
```

**Related  
Commands**

| Command | Description |
|---------|-------------|
|---------|-------------|

|                                 |                                                      |
|---------------------------------|------------------------------------------------------|
| <b>show nfpp define summary</b> | Displays the user-defined anti-attack configuration. |
|---------------------------------|------------------------------------------------------|

**Platform** N/A

**Description**

## 21.65 nfpp define policy

Use this command to set the local rate-limit threshold and the attack threshold.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp define** *name* **policy** { **per-src-ip** | **per-src-mac** | **per-port** } *rate-limit-pps* *attack-threshold-pps*

**no nfpp define** *name* **policy** {**per-src-ip** | **per-src-mac** | **per-port**}

**default nfpp define** *name* **policy** { **per-src-ip** | **per-src-mac** | **per-port** }

**Parameter Description**

| Parameter                   | Description                                                   |
|-----------------------------|---------------------------------------------------------------|
| <b>per-src-ip</b>           | Sets the attack threshold for each source IP address.         |
| <b>per-src-mac</b>          | Sets the attack threshold for each source MAC address.        |
| <b>per-port</b>             | Sets the attack threshold for each port.                      |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range from 1 to 19,999. |
| <i>attack-threshold-pps</i> | Sets the attack threshold, in the range of from 1 to 19,999.  |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the local rate-limit threshold and the attack threshold.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp define tcp policy per-src-ip 2 10
Ruijie(config-if)# nfpp define tcp policy per-port 50 100
```

**Related Commands**

| Command                         | Description                                                |
|---------------------------------|------------------------------------------------------------|
| <b>define-policy</b>            | Sets the global rate-limit threshold and attack threshold. |
| <b>show nfpp define summary</b> | Displays the user-defined anti-attack configuration.       |

**Platform** N/A

**Description**

## 21.66 nfpp dhcp-guard enable

Use this command to enable the DHCP anti-attack function on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp dhcp-guard enable**

**no nfpp dhcp-guard enable**

**default nfpp dhcp-guard enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The DHCP anti-attack function is not enabled on the interface.

**Command Mode** Interface configuration mode

**Usage Guide** The interface DHCP anti-attack configuration is prior to the global configuration

**Configuration Examples** The following example enables the DHCP anti-attack function on the interface.

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp dhcp-guard enable
```

| Related Commands | Command                             | Description                           |
|------------------|-------------------------------------|---------------------------------------|
|                  | <b>dhcp-guard enable</b>            | Enables the anti-ARP attack function. |
|                  | <b>show nfpp dhcp-guard summary</b> | Displays the configuration.           |

**Platform** N/A

**Description**

## 21.67 nfpp dhcp-guard policy

Use this command to set the rate-limit threshold and the attack threshold on the port.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp dhcp-guard policy { per-src-mac | per-port } rate-limit-pps attack-threshold-pps**

**no nfpp dhcp-guard policy { per-src-mac | per-port }**

**default nfpp dhcp-guard policy { per-src-mac | per-port }**

| Parameter Description | Parameter          | Description                                                                                   |
|-----------------------|--------------------|-----------------------------------------------------------------------------------------------|
|                       | <b>per-src-mac</b> | Sets the rate-limit threshold and the attack threshold for the designated source MAC address. |

|                             |                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------|
| <b>per-port</b>             | Sets the rate-limit threshold and the attack threshold for the designated port. |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range from 1 to 19,999.                   |
| <i>attack-threshold-pps</i> | Sets the attack threshold, in the range from 1 to 19,999.                       |

**Defaults** The rate-limit threshold and the attack threshold are not configured by default. So the device adopts the rate-limit threshold and the attack threshold that are set in the global configuration mode.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold on interface G0/1.

**Examples**

```
Ruijie(config)#interface G 0/1
Ruijie(config-if)# nfpp dhcpv6-guard policy per-src-mac 3 10
Ruijie(config-if)# nfpp dhcpv6-guard policy per-port 50 100
```

**Platform** N/A

**Description**

## 21.69 nfpp dhcpv6-guard policy

Use this command to set the rate-limit threshold and the attack threshold.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp dhcpv6-guard policy { per-src-mac | per-port } rate-limit-pps attack-threshold-pps**

**no nfpp dhcpv6-guard policy { per-src-mac | per-port }**

**default nfpp dhcpv6-guard policy { per-src-mac | per-port }**

**Parameter  
Description**

| Parameter                   | Description                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------|
| <b>per-src-mac</b>          | Sets the rate-limit threshold and the attack threshold for each source MAC address. |
| <b>per-port</b>             | Sets the rate-limit threshold and the attack threshold for each port.               |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range of from1 to 19,999.                     |
| <i>attack-threshold-pps</i> | Sets the attack threshold, in the range from1 to19,999.                             |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command  
Mode** Interface configuration mode

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp dhcpv6-guard policy per-src-mac 3 10
Ruijie(config-if)# nfpp dhcpv6-guard policy per-port 50 100
```

**Description**

## 21.70 nfpp icmp-guard enable

Use this command to enable the ICMP anti-attack function on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp icmp-guard enable**

**no nfpp icmp-guard enable**

**default nfpp icmp-guard enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** The ICMP anti-attack function is not enabled on the interface.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The interface ICMP anti- attack configuration is prior to the global configuration.

**Configuration** The following example enables the ICMP anti-attack function on the interface.

**Examples**

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp icmp-guard enable
```

| Related Commands | Command                             | Description                           |

|                  | <b>icmp-guard enable</b>            | Enables the anti-ARP attack function. |
|                  | <b>show nfpp icmp-guard summary</b> | Displays the configuration.           |

**Platform** N/A

**Description**

## 21.71 nfpp icmp-guard isolate-period

Use this command to set the isolate period in the interface configuration mode.

Use the **no** or **default** form of this command to restore the default setting.

```

nfpp icmp-guard isolate-period { seconds | permanent }
no nfpp icmp-guard isolate-period
default nfpp icmp-guard isolate-period

```

| Parameter Description | Parameter        | Description                                                                                       |
|-----------------------|------------------|---------------------------------------------------------------------------------------------------|
|                       | <i>seconds</i>   | Sets the isolate period. The value is 0 or in the range from 30 to 86,400 in the unit of seconds. |
|                       | <b>permanent</b> | Permanent isolation                                                                               |

**Defaults** By default, the isolate period is not configured.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example sets the isolate period in the interface configuration mode.

```

Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp icmp-guard isolate-period 180

```

|------------------|-------------------------------------|---------------------------------|
|                  | <b>icmp-guard isolate-period</b>    | Sets the global isolate period. |
|                  | <b>show nfpp icmp-guard summary</b> | Displays the configuration.     |

**Platform Description** N/A

## 21.72 nfpp icmp-guard policy

Use this command to set the rate-limit threshold and the attack threshold.

Use the **no** or **default** form of this command to restore the default setting.

```

nfpp icmp-guard policy { per-src-ip | per-port } rate-limit-pps attack-threshold-pps
no nfpp icmp-guard policy { per-src-ip | per-port }
default nfpp icmp-guard policy { per-src-ip | per-port }

```

| Parameter Description | Parameter             | Description                                                                        |
|-----------------------|-----------------------|------------------------------------------------------------------------------------|
|                       | <b>per-src-ip</b>     | Sets the rate-limit threshold and the attack threshold for each source IP address. |
|                       | <b>per-port</b>       | Sets the rate-limit threshold and the attack threshold for each port.              |
|                       | <i>rate-limit-pps</i> | Sets the rate-limit threshold, in the range from 1 to 19,999.                      |

|                             |                                                       |
|-----------------------------|-------------------------------------------------------|
| <i>attack-threshold-pps</i> | Sets the attack threshold, in range from 1 to 19,999. |
|-----------------------------|-------------------------------------------------------|

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command Mode** Interface configuration mode

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp icmp-guard policy per-src-ip 5 10
Ruijie(config-if)# nfpp icmp-guard policy per-port 100 200
```

**Description**

## 21.74 nfpp ip-guard isolate-period

Use this command to set the isolate period in the interface configuration mode.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp ip-guard isolate-period** { *seconds* | **permanent** }

**no nfpp ip-guard isolate-period**

**default nfpp ip-guard isolate-period**

| Parameter Description | Parameter        | Description         |
|-----------------------|------------------|---------------------|
|                       |                  | <i>seconds</i>      |
|                       | <b>permanent</b> | Permanent isolation |

**Defaults** By default, the isolate period is not configured.

**Command** Interface configuration mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example sets the isolate period in the interface configuration mode.

**Examples**

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp ip-guard isolate-period 180
```

| Related Commands | Command                           | Description                    |

**Description**

## 21.75 nfpp ip-guard policy

Use this command to set the rate-limit threshold and the attack threshold.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp ip-guard policy** { **per-src-ip** | **per-port** } *rate-limit-pps attack-threshold-pps*

**no nfpp ip-guard policy** { **per-src-ip** | **per-port** }

**default nfpp ip-guard policy** { **per-src-ip** | **per-port** }

| Parameter Description | Parameter                   | Description                                                                        |
|-----------------------|-----------------------------|------------------------------------------------------------------------------------|
|                       | <b>per-src-ip</b>           | Sets the rate-limit threshold and the attack threshold for each source IP address. |
|                       | <b>per-port</b>             | Sets the rate-limit threshold and the attack threshold for each port.              |
|                       | <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range from 1 to 19,999.                      |
|                       | <i>attack-threshold-pps</i> | Sets the attack threshold, in the range from 1 to 19,999.                          |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command Mode** Interface configuration mode

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration Examples** The following example sets the rate-limit threshold and the attack threshold.

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp ip-guard policy per-src-ip 2 10
Ruijie(config-if)# nfpp ip-guard policy per-port 50 100
```

| Related Commands | Command                           | Description                           |

**Platform** N/A  
**Description**

## 21.76 nfpp ip-guard scan-threshold

Use this command to set the scan threshold.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp ip-guard scan-threshold** *pkt-cnt*

**no nfpp ip-guard scan-threshold**

**default nfpp ip-guard scan-threshold**

| Parameter Description | Parameter      | Description                                             |
|-----------------------|----------------|---------------------------------------------------------|
|                       | <i>pkt-cnt</i> | Sets the scan threshold, in the range from 1 to 19,999. |

**Defaults** By default, the sport-based scan threshold is not configured.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the scan threshold to 20pps.

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp ip-guard scan-threshold 20
```

| Related Commands | Command                           | Description                       |

|                  | <b>ip-guard attack-threshold</b>  | Sets the global attack threshold. |
|                  | <b>show nfpp ip-guard summary</b> | Displays the configuration.       |

**Platform** N/A

**Description**

## 21.77 nfpp nd-guard enable

Use this command to enable the ND anti-attack function on the interface.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp nd-guard enable**

**no nfpp nd-guard enable**

**default nfpp nd-guard enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** The ND anti-attack function is disabled on the interface.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The interface ND anti-attack configuration is prior to the global configuration.

**Configuration** The following example enables the ND anti-attack function on the interface.

**Examples**

```
Ruijie(config)# interface G0/1
Ruijie(config-if)# nfpp nd-guard enable
```

**Related  
Commands**

| Command                           | Description                          |
|-----------------------------------|--------------------------------------|
| <b>nd-guard enable</b>            | Enables the ND anti-attack function. |
| <b>show nfpp nd-guard summary</b> | Displays the configuration.          |

**Platform** N/A

**Description**

## 21.78 nfpp nd-guard policy

Use this command to set the rate-limit threshold and the attack threshold.

Use the **no** or **default** form of this command to restore the default setting.

**nfpp nd-guard policy per-port { ns-na | rs | ra-redirect } rate-limit-pps attack-threshold-pps**

**no nfpp nd-guard policy per-port { ns-na | rs | ra-redirect }**

**default nfpp nd-guard policy per-port { ns-na | rs | ra-redirect }**

**Parameter  
Description**

| Parameter                   | Description                                                   |
|-----------------------------|---------------------------------------------------------------|
| <b>ns-na</b>                | Sets the neighbor request and neighbor advertisement.         |
| <b>rs</b>                   | Sets the router request.                                      |
| <b>ra-redirect</b>          | Sets the router advertisement and the redirect packets.       |
| <i>rate-limit-pps</i>       | Sets the rate-limit threshold, in the range from 1 to 19,999. |
| <i>attack-threshold-pps</i> | Sets the attack threshold, in the range from 1 to 19,999.     |

**Defaults** By default, the rate-limit threshold and the attack threshold are not configured.

**Command** Interface configuration mode

**Mode**

**Usage Guide** The attack threshold value shall be equal to or greater than the rate-limit threshold.

**Configuration** The following example sets the rate-limit threshold and the attack threshold.

**Examples**

```
Ruijie(config)# interface G 0/1
Ruijie(config-if)# nfpp nd-guard policy per-port ns-na 50 100
Ruijie(config-if)# nfpp nd-guard policy per-port rs 10 20
Ruijie(config-if)# nfpp nd-guard policy per-port ra-redirect 10 20
```

## 21.79 show nfpp arp-guard hosts

Use this command to display the monitored host.

```
show nfpp arp-guard hosts [ statistics | [ [ vlan vid ] [ interface interface-id ] [ ip-address | mac-address ] ] ]
```

**Parameter  
Description**

| Parameter           | Description                                                 |
|---------------------|-------------------------------------------------------------|
| <b>statistics</b>   | Displays the statistical information of the monitored host. |
| <i>vid</i>          | The VLAN ID                                                 |
| <i>interface-id</i> | The interface name                                          |
| <i>ip-address</i>   | The IP address                                              |
| <i>mac-address</i>  | The MAC address                                             |

**Defaults** N/A**Command** Privileged EXEC mode**Mode****Usage Guide** N/A**Configuration** The following example displays the statistical information of the monitored host.**Examples**

```
Ruijie# show nfpp arp-guard hosts statistics
success    fail    total
-----    ----    -----
100        20     120
```

The following example shows the monitored host.

```
Ruijie# show nfpp arp-guard hosts
If column 1 shows '*', it means "hardware do not isolate user" .
```

| VLAN          | interface | IP address | MAC address    | remain-time(s) |
|---------------|-----------|------------|----------------|----------------|
| 1             | Gi0/1     | 1.1.1.1    | -              | 110            |

**Description**

## 21.80 show nfpp arp-guard scan

Use this command to display the ARP scan list.

```
show nfpp arp-guard scan [ statistics ] [ [ vlan vid ] [ interface interface-id ] [ ip-address ] [ mac-address ] ]
```

#### Parameter Description

| Parameter           | Description                                                |
|---------------------|------------------------------------------------------------|
| <b>statistics</b>   | Displays the statistical information of the ARP scan list. |
| <i>vid</i>          | The VLAN ID                                                |
| <i>interface-id</i> | The interface name                                         |
| <i>ip-address</i>   | The IP address                                             |
| <i>mac-address</i>  | The MAC address                                            |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the ARP scan list.

```
Ruijie# show nfpp arp-guard scan statistics
arp-guard table has 4 record(s).
```

The following example displays the ARP scan list.

```
Ruijie# show nfpp arp-guard scan
VLAN   interface  IP address  MAC address  timestamp
----   -
1      Gi0/1     1.1.1.1    -            110
2      Gi0/2     1.1.2.1    -            61
*3     Gi0/3     -          0000.0000.1111  110
4      Gi0/4     -          0000.0000.2222  61
```

```

1      Gi0/1      -      0000.0000.0001  2008-01-23 16:23:10
2      Gi0/2      1.1.1.1      0000.0000.0002  2008-01-23 16:24:10

#### Description

## 21.82 show nfpp define hosts

Use this command to display the monitored hosts.

```
show nfpp define hosts name [statistics | [[vlan vid] [interface interface-id] [ip-address]
[mac-address] [ipv6-address]]]
```

#### Parameter Description

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                     |                                             |
|---------------------|---------------------------------------------|
| <i>name</i>         | Name of the user-defined anti-attack type   |
| <b>statistics</b>   | Displays the statistics of monitored hosts. |
| <i>vid</i>          | VLAN ID                                     |
| <i>interface-id</i> | Interface name                              |
| <i>ip-address</i>   | IP address                                  |
| <i>mac-address</i>  | MAC address                                 |
| <i>ipv6-address</i> | IPv6 address                                |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** This command allows filtering the hosts with parameters specified

**Configuration** The following example displays the monitored hosts.

**Examples**

```
Ruijie#show nfpp define hosts abc
If col_filter 1 shows '*', it means "hardware do not isolate host".
VLAN   interface  MAC address   remain-time(s)
----   -
*1     Gi4/2       00d0.f822.33e5 592
Total: 1 host
```

|--------------------------------|--------------------------------------------------------------|
| <b>clear nfpp define hosts</b> | Clears the monitored hosts of user-defined anti-attack type. |

**Platform** N/A

**Description**

## 21.83 show nfpp define summary

Use this command to display the configuration.

**show nfpp define summary** [ *name* ]

**Parameter  
Description**

| Parameter   | Description                               |
|-------------|-------------------------------------------|
| <i>name</i> | Name of the user-defined anti-attack type |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** This command can be used to display the configuration. Without the name specified, all user-defined anti-attack types will be displayed.

**Configuration** The following example displays the configuration.

**Examples**

```
Ruijie#show nfpp define summary abc
Define abc summary:
match etype 0x800 src-ip 1.1.1.1 src-ip-mask 255.255.255.255
Maximum count of monitored hosts: 20000
Monitor period:600s
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status Rate-limit Attack-threshold
Global Disable -/10/- -/20/-
Gi4/1 Enable -/-/- -/-/-
```

| Field            | Description                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface        | If the interface field is displayed as Global, it means that is configured in the global configuration mode.                                                    |
| Status           | Enables/ Disables the anti-attack function.                                                                                                                     |
| Rate-limit       | In the format of the rate-limit threshold for the source IP address/ the rate-limit threshold for the source MAC address/ the rate-limit threshold for the port |
| Attack-threshold | In the same format as the rate-limit.                                                                                                                           |

**Related Commands**

| Command                     | Description                                                  |
|-----------------------------|--------------------------------------------------------------|
| <b>match</b>                | Clears the monitored hosts of user-defined anti-attack type. |
| <b>policy</b>               | Attack threshold and rate-limit threshold.                   |
| <b>isolate-period</b>       | Isolates time                                                |
| <b>monitored-period</b>     | Monitored time                                               |
| <b>monitored-host-limit</b> | Maximum monitored host number                                |

**Description**

## 21.84 show nfpp define trusted-host

Use this command to display the trusted host free from monitoring.

**show nfpp define trusted-host** *name*

**Parameter**

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <b>Description</b> |                                                       |
|                    | <i>name</i> Name of the user-defined anti-attack type |

**Defaults** N/A.

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the trusted host configuration.

**Examples**

```
Ruijie# show nfpp define trusted-host tcp
Define tcp:
IP address      mask
-----      -
1.1.1.0        255.255.255.0
1.1.2.0        255.255.255.0
Total:2 record(s)
```

|                         |                     |                               |

|                         | <b>trusted-host</b> | Configures the trusted hosts. |

**Platform Description** N/A

## 21.85 show nfpp dhcp-guard hosts

Use this command to display the monitored host.

**show nfpp dhcp-guard hosts** [**statistics** | [[**vlan** *vid*] [**interface** *interface-id*] [*mac-address*]]]

|                              |                     |                                                             |
|------------------------------|---------------------|-------------------------------------------------------------|
| <b>Parameter Description</b> | <b>Parameter</b>    | <b>Description</b>                                          |
|                              | <b>statistics</b>   | Displays the statistical information of the monitored host. |
|                              | <i>vid</i>          | VLAN ID                                                     |
|                              | <i>interface-id</i> | Interface name                                              |
|                              | <i>mac</i>          | MAC address                                                 |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the monitored host.

```

Examples Ruijie# show nfpp dhcp-guard hosts statistics
success    fail    total
-----    ----    -----
100        20     120

```

The following example displays the monitored host.

```

Ruijie# show nfpp dhcp-guard hosts
If column 1 shows '*', it means "hardware failed to isolate host".
VLAN interface MAC address remain-time(seconds)
----  -
1     gi0/2     0000.0000.0001  10
*2    gi0/1     0000.0000.0002  20
Total:2 host(s)

```

## 21.87 show nfpp dhcpv6-guard hosts

Use this command to display the monitored host.

**show nfpp dhcpv6-guard hosts** [**statistics** | [[**vlan** *vid*] [**interface** *interface-id*] [*mac-address*]]]

**Parameter Description**

| Parameter         | Description                                                 |
|-------------------|-------------------------------------------------------------|
| <b>statistics</b> | Displays the statistical information of the monitored host. |

|                     |                    |
|---------------------|--------------------|
| <i>vid</i>          | The VLAN ID        |
| <i>interface-id</i> | The interface name |
| <i>mac-address</i>  | The MAC address    |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the monitored host.

**Examples**

```
Ruijie# show nfpp dhcpv6-guard hosts
If column 1 shows '*', it means "hardware failed to isolate host".
VLAN interface MAC address remain-time(seconds)
-----
*1 gi0/2 0000.0000.0001 10
*2 gi0/1 0000.0000.0002 20
Total:2 host(s)
```

**Related Commands**

**Description**

## 21.88 show nfpp dhcpv6-guard summary

Use this command to display the configuration.

**show nfpp dhcpv6-guard summary**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the configuration.

**Examples**

```
Ruijie#show nfpp dhcpv6-guard summary
```

```
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
```

```
Interface Status Rate-limit Attack-threshold
Global Enable -/5/1200 -/10/1500
```

```
Maximum count of monitored hosts: 20000
```

```
Monitor period: 600s
```

**Description**

## 21.89 show nfpp icmp-guard hosts

Use this command to display the monitored host.

```
show nfpp icmp-guard hosts [statistics | [[vlan vid] [interface interface-id] [ip-address]]]
```

**Parameter Description**

| Parameter         | Description                                                 |
|-------------------|-------------------------------------------------------------|
| <b>statistics</b> | Displays the statistical information of the monitored host. |
| <i>vid</i>        | The VLAN ID                                                 |

|                     |                    |
|---------------------|--------------------|
| <i>interface-id</i> | The interface name |
| <i>ip-address</i>   | The IP address     |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the monitored host.

**Examples**

```
Ruijie# show nfpp icmp-guard hosts statistics
success    fail    total
-----    ----    -----
100        20     120
```

The following example displays the monitored host.

```
Ruijie# show nfpp icmp-guard hosts
If column 1 shows '*', it means "hardware failed to isolate host".
VLAN interface IP address      remain-time(s)
----  -
1     Gi0/1      1.1.1.1      110
2     Gi0/2      1.1.2.1      61
Total:2 host(s)
```

**Description**

## 21.92 show nfpp ip-guard hosts

Use this command to display the monitored host.

**show nfpp ip-guard hosts** [**statistics** | [[**vlan** *vid*] [**interface** *interface-id*] [*ip-address*]]]

| Parameter Description | Parameter           | Description                                                 |
|-----------------------|---------------------|-------------------------------------------------------------|
|                       | <b>statistics</b>   | Displays the statistical information of the monitored host. |
|                       | <i>vid</i>          | The VLAN ID.                                                |
|                       | <i>interface-id</i> | The interface name.                                         |
|                       | <i>mac-address</i>  | The MAC address.                                            |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the monitored host.

**Examples**

```
Ruijie# show nfpp ip-guard hosts statistics
success   fail    total
-----   ----   -----
100       20     120
```

The following example displays the monitored host.

```
Ruijie#show nfpp ip-guard hosts
If column 1 shows '*', it means "hardware do not isolate host" .
VLAN  interface IP address  Reason      remain-time(s)
----  -
1     Gi0/1      1.1.1.1    ATTACK      110
2     Gi0/2      1.1.2.1    SCAN        61
Total:2 host(s)
```

**Related Commands**

| Command                          | Description                |
|----------------------------------|----------------------------|
| <b>clear nfpp ip-guard hosts</b> | Clears the monitored host. |

**Platform Description** N/A

## 21.93 show nfpp ip-guard summary

Use this command to display the configuration.

**show nfpp ip-guard summary**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the configuration.

**Examples**

```
Ruijie# show nfpp ip-guard summary
(Format of column Rate-limit and Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status Isolate-period Rate-limit Attack-threshold Scan-threshold
Global      Enable  300          4/-/60      8/-/100     15
Gi 0/1      Enable  180          5/-/-       8/-/-       -
Gi 0/2      Disable 200          4/-/60      8/-/100     20

Maximum count of monitored hosts: 1000
Monitor period..300s
```

| Field             | Description                                                                                                                                                     |

| <b>nfpp ip-guard enable</b>          | Enables the IP anti-attack function on the interface. |
| <b>nfpp ip-guard isolate-period</b>  | Sets the isolate time.                                |
| <b>nfpp ip-guard policy</b>          | Sets the rate-limit threshold and attack threshold.   |

**Platform** N/A

**Description**

## 21.94 show nfpp ip-guard trusted-host

Use this command to display the trusted host free from being monitored.

**show nfpp ip-guard trusted-host**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the trusted host free from being monitored.

**Examples**

```
Ruijie# show nfpp ip-guard trusted-host
IP address      mask
-----
1.1.1.0         255.255.255.0
1.1.2.0         255.255.255.0
Total.2 record(s)
```

| Related Commands | Command                      | Description            |
|------------------|------------------------------|------------------------|
|                  | <b>ip-guard trusted-host</b> | Sets the trusted host. |

**Platform Description** N/A

## 21.95 show nfpp log

Use this command to display the NFPP log configuration.

### **show nfpp log summary**

Use this command to display the NFPP log buffer area content.

### **show nfpp log buffer [ statistics ]**

| Parameter Description | Parameter         | Description                                                       |
|-----------------------|-------------------|-------------------------------------------------------------------|
|                       | <b>statistics</b> | Displays the statistical information of the NFPP log buffer area. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** When the log buffer area is full, the subsequent logs are to be dropped, and an entry with all attributes "-" is displayed in the log buffer area. The administrator shall increase the capacity of the log buffer area or improve the rate of generating the syslog.

The generated syslog in the log buffer area carries with the timestamp, for example:

%NFPP\_ARP\_GUARD-4-DOS\_DETECTED:

Host<IP=N/A,MAC=0000.0000.0004,port=Gi4/1,VLAN=1> was detected.(2009-07-01 13:00:00)

**Configuration** The following example displays the NFPP log configuration.

```
Examples Ruijie#show nfpp log summary
Total log buffer size : 10
Syslog rate : 1 entry per 2 seconds
Logging:
VLAN 1-3, 5
interface Gi 0/1
interface Gi 0/2
```

The following example displays the log number in the buffer area.

```
Ruijie#show nfpp log buffer statistics
There are 6 logs in buffer.
```

The following example shows the NFPP log buffer area:

```
Ruijie#show nfpp log buffer
Protocol VLAN Interface IP address MAC address Reason Timestamp
-----
ARP 1 Gi0/1 1.1.1.1 - DoS 2009-05-30
16:23:10

## 21.96 show nfpp nd-guard summary

Use this command to display the configuration.

**show nfpp nd-guard summary**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** N/A

**Configuration** The following example displays the configuration.

**Examples**

```
Ruijie# show nfpp nd-guard summary
(Format of column Rate-limit and Attack-threshold is NS-NA/RS/RA-REDIRECT.)
Interface Status Rate-limit Attack-threshold
Global      Enable  20/5/10   40/10/20
Gi 0/1      Enable  15/15/15  30/30/30
Gi 0/2      Disable -/5/30    -/10/50
```

| Field             | Description                                                             |
|-------------------|-------------------------------------------------------------------------|
| Interface(Global) | Global configuration                                                    |
| Status            | Enables/Disables the anti-attack function.                              |
| Rate-limit        | In the format of the rate-limit threshold for the NS-NA/RS/RA-REDIRECT. |
| Attack-threshold  | In the same format as the rate-limit.                                   |

## 21.97 show nfpp nd-guard hosts

Use this command to display the monitored host.

**show nfpp nd-guard hosts** [**statistics** | [[**vlan** *vid*] [**interface** *interface-id*]]]

**Parameter Description**

| Parameter           | Description                                    |
|---------------------|------------------------------------------------|
| <b>statistics</b>   | Displays the statistics of the monitored host. |
| <i>vid</i>          | Sets the VLAN ID.                              |
| <i>interface-id</i> | Sets the interface name and number.            |

**Command Mode**

Privileged EXEC mode

**Usage Guide**

N/A

**Configuration**

The following example displays the statistics of the host monitored by ND-guard.

**Examples**

```
Ruijie#show nfpp nd-guard hosts statistics
success   fail    total
-----   -
10        2      12
```

The following example displays the host monitored by ND-guard. The “remain-time(s)” refers to the remaining time of isolation.

```
Ruijie#show nfpp nd-guard hosts
If col_filter 1 shows '*', it means "hardware do not isolate host".
VLAN   interface  ND-guard      remain-time(s)
-----
-      Gi4/2      ns-na-guard    174
-      Gi4/2      rs-guard       98
-      Gi4/2      ra-redirect-guard 127
Total: 3 hosts
```

**Platform** N/A**Description**

## 21.98 trusted-host

Use this command to set the trusted hosts free form monitoring.

Use the **no** or **default** form of this command to restore the default setting,  
**trusted-host** { *mac mac\_mask* | *ip mask* | *IPv6/prefixlen* }  
**no trusted-host** { **all** | *mac mac\_mask* | *ip mask* | *IPv6/prefixlen* }  
**default trusted-host**

| Parameter Description | Parameter             | Description                                                                      |
|-----------------------|-----------------------|----------------------------------------------------------------------------------|
|                       | <i>ip</i>             | Sets the IP address                                                              |
|                       | <i>mac</i>            | MAC address                                                                      |
|                       | <i>mac_mask</i>       | MAC address mask                                                                 |
|                       | <i>IPv6/prefixlen</i> | IPv6 address and mask length                                                     |
|                       | <i>mask</i>           | IP mask                                                                          |
|                       | <b>all</b>            | Deletes the configuration of all trusted hosts with the no form of this command. |

**Defaults** N/A

**Command** NFPP define configuration mode

**Mode**

**Usage Guide** The administrator can use this command to set the trusted host free from monitoring. The ICMP packets are allowed to be sent to the trusted host CPU without any rate-limit and warning configuration. Configure the mask to set all hosts in one network segment free from monitoring. UP to 500 trusted hosts are supported.

Before configuring the trusted-host, the match type must be configured. If the message type configured by the match is Ipv4, the Ipv6 trusted addresses are not allowed. In the same way, if the message type is IPv6, the IPv4 trusted addresses are not allowed.

**Configuration** The following example sets the trusted hosts free form monitoring.

**Examples**

```
Ruijie(config)# nfpp
Ruijie(config-nfpp)# define tcp
Ruijie(config-nfpp-define)#trusted-host 1.1.1.1 255.255.255.255
```

**Related Commands**

| Command                              | Description                              |
|--------------------------------------|------------------------------------------|
| <b>show nfpp define trusted-host</b> | Displays the trusted host configuration. |

**Platform** N/A

**Description**

## 21.99 no all-guard enable

Use this command to disable all NFPP guards (except guards self-defined and enabled in interface configuration mode).

**no all-guard enable**

Use this command to enable all NFPP guards.

**all-guard enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Command Mode**  
NFPP configuration mode

- Usage Guide**
- By default, all basic NFPP guards are enabled.
  - This global command supports basic NFPP guards including ARP-GUARD, IP-GUARD, ICMP-GUARD, DHCP-GUARD, DHCPv6-GUARD and ND-GUARD.
  - The **no** form command will disable all guards, which is displayed guard-by-guard by using the **show running-config** command. The exception is guards self-defined and configured in interface configuration mode.

**Configuration Examples**

```
Ruijie(config)#show running-config | begin nfpp
nfpp
  log-buffer enable
  arp-guard rate-limit per-port 201
  arp-guard attack-threshold per-port 210
!
Ruijie(config)# nfpp
Ruijie(config-nfpp)#no all-guard enable
Ruijie(config-nfpp)#show running-config | begin nfpp
nfpp
  log-buffer enable
  no arp-guard enable
  arp-guard rate-limit per-port 201
  arp-guard attack-threshold per-port 210
  no icmp-guard enable
  no ip-guard enable
  no dhcp-guard enable
  no dhcpv6-guard enable
  no nd-guard enable
!
Ruijie(config-nfpp)#all-guard enable
Ruijie(config-nfpp)#show running-config | begin nfpp
nfpp
  log-buffer enable
  arp-guard rate-limit per-port 201
  arp-guard attack-threshold per-port 210
!
```

```
no service password-encryption
!
```

**Platform** N/A  
**Description**

## 22 DoS Protection Commands

### 22.1 ip deny invalid-l4port

Use this command to enable the anti-attack of the self-consumption.

Use the **no** form of this command to restore the default setting.

**ip deny invalid-l4port**

**no ip deny invalid-l4port**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables the anti-attack of the self-consumption.

```
Ruijie(config)# ip deny invalid-l4port
```

The following example disables the anti-attack of the self-consumption.

```
Ruijie(config)# no ip deny invalid-l4port
```

| Related Commands | Command                            | Description                                                |
|------------------|------------------------------------|------------------------------------------------------------|
|                  | <b>show ip deny invalid-l4port</b> | Displays the state of anti-attack of the self-consumption. |

**Platform** N/A

**Description**

### 22.2 ip deny invalid-tcp

Use this command to enable the anti-attack of the invalid TCP packets.

Use the **no** form of this command to restore the default setting.

**ip deny invalid-tcp**

**no ip deny invalid-tcp**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** The function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables the anti-attack of the invalid TCP packets:

```
Ruijie(config)# ip deny invalid-tcp
```

The following example disables the anti-attack of the invalid TCP packets:

```
Ruijie(config)# no ip deny invalid-tcp
```

|                     |         | <b>show ip deny invalid-tcp</b> |

**Platform Description** N/A

## 22.3 ip deny land

Use this command to enable the anti-land-attack.

Use the **no** form of this command to restore the default setting.

**ip deny land**

**no ip deny land**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration** The following example enables the anti-land-attack:

**Examples**

```
Ruijie(config)# ip deny land
```

The following example disables the anti-land-attack:

```
Ruijie(config)# no ip deny land
```

| <b>show ip deny land</b> | Displays the anti-land-attack state. |

**Platform** N/A

**Description**

## 22.4 show ip deny

Use this command to display the state of the anti-DOS-attack.

**show ip deny**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command  
Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the state of the anti-DOS-attack.

**Examples**

```
ruijie#show ip deny
  Protect against Land attack          On
  Protect against invalid L4port attack Off
  Protect against invalid TCP attack   Off
```

## 1.1 Command ID Table

For IDs used in the following commands, refer to the command ID table below:

| ID                   | Meaning                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID                   | Number of access list. Range:<br>Standard IP ACL: 1 to 99, 1300 to 1999<br>Extended IP ACL: 100 to 199,2000 to 2699<br>Extended MAC ACL: 700 to 799<br>Extended expert ACL: 2700 to 2899                                                                                                                                                                           |
| name                 | ACL name                                                                                                                                                                                                                                                                                                                                                           |
| sn                   | ACL SN (products can be set according to the priority)                                                                                                                                                                                                                                                                                                             |
| start-sn             | Start sequence number                                                                                                                                                                                                                                                                                                                                              |
| inc-sn               | Sequence number increment                                                                                                                                                                                                                                                                                                                                          |
| deny                 | If matched, access is denied.                                                                                                                                                                                                                                                                                                                                      |
| permit               | If matched, access is permitted.                                                                                                                                                                                                                                                                                                                                   |
| port                 | Protocol number. For IPv6, this field can be IPv6, ICMP, TCP, UDP and numbers 0 to 255. For IPv4, it can be one of EIGRP, GRE, IPINIP, IGMP, NOS, OSPF, ICMP, UDP, TCP,AHP, ESP, PCP, PIM and IP, or it can be numbers 0 to 255 that represent the IP protocol. It is described when some important protocols, such as ICMP, TCP and UDP, are listed individually. |
| interface <i>idx</i> | Interface index                                                                                                                                                                                                                                                                                                                                                    |
| src                  | Packet source IP address (host address or network address)                                                                                                                                                                                                                                                                                                         |
| src-wildcard         | Source IP address wildcard. It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                                                                                                                                                      |
| src-ipv6-pfix        | Source IPv6 network address or network type                                                                                                                                                                                                                                                                                                                        |
| dst-ipv6-pfix        | Destination IPv6 network address or network type                                                                                                                                                                                                                                                                                                                   |
| pfix-len             | Prefix mask length                                                                                                                                                                                                                                                                                                                                                 |
| src-ipv6-addr        | Source IPv6 address                                                                                                                                                                                                                                                                                                                                                |
| dst-ipv6-addr        | Destination IPv6 address                                                                                                                                                                                                                                                                                                                                           |
| dscp                 | Differential service code point, and code point value. Range: 0 to 63                                                                                                                                                                                                                                                                                              |
| flow-label           | Flow label in the range 0 to 1048575                                                                                                                                                                                                                                                                                                                               |
| dst                  | Packet destination IP address (host address or network address)                                                                                                                                                                                                                                                                                                    |
| dst-wildcard         | Destination IP address wildcard. It can be discontinuous, such as 0.255.0.32                                                                                                                                                                                                                                                                                       |
| fragment             | Packet fragment filtering.                                                                                                                                                                                                                                                                                                                                         |

|                               |                                                                                                                                                                                                          |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| precedence                    | Packet precedence value (0 to 7)                                                                                                                                                                         |
| range                         | The layer 4 port number range of the packet.                                                                                                                                                             |
| time-range <i>tm-rng-name</i> | Time range of packet filtering, named <i>tm-rng-name</i>                                                                                                                                                 |
| tos                           | Type of service (0 to 15)                                                                                                                                                                                |
| cos                           | Class of service (0-7)                                                                                                                                                                                   |
| cos inner <i>cos</i>          | COS of the packet tag                                                                                                                                                                                    |
| icmp-type                     | ICMP message type (0 to 255)                                                                                                                                                                             |
| icmp-code                     | ICMP message type code (0 to 255)                                                                                                                                                                        |
| icmp-message                  | ICMP message type name (0 to 255)                                                                                                                                                                        |
| operator port[port]           | Operator (lt-smaller, eq-equal, gt-greater, neq-unequal, range-range)<br><i>port</i> indicates the port number. Dyadic operation needs two port numbers, while other operators only need one port number |
| src-mac-addr                  | Physical address of the source host                                                                                                                                                                      |
| dst-mac-addr                  | Physical address of the destination host                                                                                                                                                                 |
| VID <i>vid</i>                | VLAN ID                                                                                                                                                                                                  |
| VID inner <i>vid</i>          | VID of the tag                                                                                                                                                                                           |
| ethernet-type                 | Ethernet protocol type. 0x value can be entered.                                                                                                                                                         |
| match-all <i>tcpf</i>         | Match all bits of the TCP flag.                                                                                                                                                                          |
| established                   | Match the RST or ACK bit of the TCP flag.                                                                                                                                                                |
| <i>text</i>                   | Remark text                                                                                                                                                                                              |
| <i>in</i>                     | Filter the incoming packets of the interface                                                                                                                                                             |
| <i>out</i>                    | Filter the outgoing packets of the interface                                                                                                                                                             |
| {rule mask offset}+           | rule: Hexadecimal value field; mask: Hexadecimal mask field<br>offset: Refer to the offset table<br>“+” sign indicates at least one group                                                                |
| log                           | Output the matching syslog when the packet matches the ACL rule.                                                                                                                                         |

| Letter | Meaning                                       | Offset | Letter | Meaning                | Offset |
|--------|-----------------------------------------------|--------|--------|------------------------|--------|
| A      | Destination MAC                               | 0      | O      | TTL field              | 34     |
| B      | Source MAC                                    | 6      | P      | Protocol number        | 35     |
| C      | Data frame length field                       | 12     | Q      | IP check sum           | 36     |
| D      | VLAN tag field                                | 14     | R      | Source IP address      | 38     |
| E      | DSAP (Destination Service Access Point) field | 18     | S      | Destination IP address | 42     |
| F      | SSAP (Source Service Access Point) field      | 19     | T      | TCP source port        | 46     |
| G      | Ctrl field                                    | 20     | U      | TCP destination port   | 48     |

|   |                        |    |    |                                    |    |
|---|------------------------|----|----|------------------------------------|----|
| H | Org Code field         | 21 | V  | Sequence number                    | 50 |
| I | Encapsulated data type | 24 | W  | Confirmation field                 | 54 |
| J | IP version number      | 26 | XY | IP header length and reserved bits | 58 |
| K | TOS field              | 27 | Z  | Resrved bits and flags bit         | 59 |
| L | Length of IP packet    | 28 | a  | Windows size field                 | 60 |
| M | ID                     | 30 | b  | Others                             | 62 |
| N | Flags field            | 32 |    |                                    |    |

## 1.2 access-list

Use this command to create an access list to filter data packets. Use the **no** form of this command to remove the specified access list.

- Standard IP access list (1 to 99, 1300 to 1999)

```
access-list id { deny | permit } { source source-wildcard | host source | any | interface idx }
[time-range tm-range-name] [log]
```

- Extended IP access list (100 to 199, 2000 to 2699)

```
access-list id {deny | permit} protocol {source source-wildcard | host source | any} interface idx }
{destination destination-wildcard | host destination | any} [precedence precedence] [tos tos] | [dscp
dscp] [fragment] [range lower upper] [time-range time-range-name] [log]
```

- Extended MAC access list (700 to 799)

```
access-list id {deny | permit} {any | host source-mac-address | source-mac-address mask } {any |
host destination-mac-address | destination-mac-address mask } [ethernet-type][cos [out][inner in]]
```

- Extended expert access list (2700 to 2899)

```
access-list id {deny | permit} [protocol] [ethernet-type][cos [out][inner in]] [VID [out][inner in]]
{source source-wildcard | host source | any} {host source-mac-address | any} {destination
destination-wildcard | host destination | any} {host destination-mac-address | any} [precedence
precedence] [tos tos] | [dscp dscp] [fragment] [time-range time-range-name]
```

- When you select the Ethernet-type field or cos field:

```
access-list id {deny | permit} [ethernet-type]/cos [out][inner in]] [VID [out][inner in]] {source
source-wildcard | host source | any} {host source-mac-address | any} {destination
destination-wildcard | host destination | any} {host destination-mac-address | any} [time-range
time-range-name]
```

- When you select the protocol field:

```
access-list id {deny | permit} protocol [VID [out][inner in]] {source source-wildcard | host source |
any} {host source-mac-address | any} {destination destination-wildcard | host destination | any}
{host destination-mac-address | any} [precedence precedence] [tos tos] | [dscp dscp] [fragment]
[range lower upper] [time-range time-range-name]
```

- Extended expert ACLs of some important protocols:

### Internet Control Message Protocol (ICMP)

```
access-list id {deny | permit} icmp [VID [out][inner in]] {source source-wildcard | host source | any}
{host source-mac-address | any} {destination destination-wildcard | host destination | any} {host
destination-mac-address | any} [icmp-type] [ [ icmp-type [icmp-code] ] ] [ icmp-message ] ]
[precedence precedence] [tos tos] | [dscp dscp] [fragment] [time-range time-range-name]
```

**Transmission Control Protocol (TCP)**

**access-list** *id* {deny | permit} tcp [VID [out][inner in]]{source source-wildcard | host Source | any} {host source-mac-address | any } ] {destination destination-wildcard | host destination | any} {host destination-mac-address | any} ] [precedence precedence] [tos tos] | [dscp dscp] [fragment] [range lower upper] [time-range time-range-name] [ match-all tcp-flag | established ]

**User Datagram Protocol (UDP)**

**access-list** *id* { deny | permit } udp[ VID [ out ] [ inner in ] ] { source source –wildcard | host source | any } { host source-mac-address | any } ] { destination destination-wildcard | host destination | any } { host destination-mac-address | any } [ [precedence precedence ] [ tos tos ] | [dscp dscp]] [ fragment ] [ range lower upper ][ time-range time-range-name ]

**Parameter Description**

| Parameter                      | Description                                                                                                                                                                                                                                            |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>id</i>                      | Access list number. The ranges available are 1 to 99, 100 to 199, 1300 to 1999, 2000 to 2699, 2700 to 2899, and 700 to 799.                                                                                                                            |
| <b>deny</b>                    | If not matched, access is denied.                                                                                                                                                                                                                      |
| <b>permit</b>                  | If matched, access is permitted.                                                                                                                                                                                                                       |
| <i>source</i>                  | Specify the source IP address (host address or network address).                                                                                                                                                                                       |
| <i>source-wildcard</i>         | It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                                                                      |
| <i>protocol</i>                | IP protocol number. It can be one of EIGRP, GRE, IPINIP, IGMP, NOS, OSPF, ICMP, UDP, TCP, and IP. It can also be a number representing the IP protocol between 0 and 255. The important protocols such as ICMP, TCP, and UDP are described separately. |
| <i>destination</i>             | Specify the destination IP address (host address or network address).                                                                                                                                                                                  |
| <i>destination-wildcard</i>    | Wildcard of the destination IP address. It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                              |
| <b>fragment</b>                | Packet fragment filtering                                                                                                                                                                                                                              |
| <b>precedence</b>              | Specify the packet priority.                                                                                                                                                                                                                           |
| <i>precedence</i>              | Packet precedence value (0 to 7)                                                                                                                                                                                                                       |
| <b>range</b>                   | Layer4 port number range of the packet.                                                                                                                                                                                                                |
| <i>lower</i>                   | Lower limit of the layer4 port number.                                                                                                                                                                                                                 |
| <i>upper</i>                   | Upper limit of the layer4 port number.                                                                                                                                                                                                                 |
| <b>time-range</b>              | Time range of packet filtering                                                                                                                                                                                                                         |
| <i>time-range-name</i>         | Time range name of packet filtering                                                                                                                                                                                                                    |
| <b>tos</b>                     | Specify type of service.                                                                                                                                                                                                                               |
| <i>tos</i>                     | ToS value (0 to 15)                                                                                                                                                                                                                                    |
| <b>dscp</b>                    | Differentiated service code point                                                                                                                                                                                                                      |
| <i>dscp</i>                    | Code point value, ranging from 0 to 63                                                                                                                                                                                                                 |
| <i>icmp-type</i>               | ICMP message type (0 to 255)                                                                                                                                                                                                                           |
| <i>icmp-code</i>               | ICMP message type code (0 to 255)                                                                                                                                                                                                                      |
| <i>icmp-message</i>            | ICMP message type name                                                                                                                                                                                                                                 |
| <b>host source-mac-address</b> | Source physical address                                                                                                                                                                                                                                |
| <b>host</b>                    | Destination physical address                                                                                                                                                                                                                           |

|                         |                                                            |
|-------------------------|------------------------------------------------------------|
| destination-mac-address |                                                            |
| <b>VID</b> vid          | Match the specified VID.                                   |
| <i>ethernet-type</i>    | Ethernet type                                              |
| <b>match-all</b>        | Match all the bits of the TCP flag.                        |
| <i>tcp-flag</i>         | Match the TCP flag.                                        |
| <b>established</b>      | Match the RST or ACK bits, not other bits of the TCP flag. |

**Defaults** N/A

**Command** Global configuration mode.

**Mode**

**Usage Guide** To filter the data by using the access control list, you must first define a series of rule statements by using the access list. You can use ACLs of the appropriate types according to the security needs:

The standard IP ACL (1 to 99, 1300 to 1999) only controls the source IP addresses.

The extended IP ACL (100 to 199, 2000 to 2699) can enforce strict control over the source and destination IP addresses.

The extended MAC ACL (700 to 799) can match against the source/destination MAC addresses and Ethernet type.

The extended expert access list (2700 to 2899) is a combination of the above and can match and filter the VLAN ID.

For the layer-3 routing protocols including the unicast routing protocol and multicast routing protocol, the following parameters are not supported by the ACL: **precedence** *precedence/tos tos/fragments/range lower upper/time-range time-range-name*

The TCP Flag includes part or all of the following:

- urg
- ack
- psh
- rst
- syn
- fin

The packet precedence is as below:

- critical
- flash
- flash-override
- immediate
- internet
- network
- priority
- routine

The service types are as below:

- max-reliability

- max-throughput
- min-delay
- min-monetary-cost
- normal

The ICMP message types are as below:

- administratively-prohibited
- dod-host-prohibited
- dod-net-prohibited
- echo
- echo-reply
- fragment-time-exceeded
- general-parameter-problem
- host-isolated
- host-precedence-unreachable
- host-redirect
- host-tos-redirect
- host-tos-unreachable
- host-unknown
- host-unreachable
- information-reply
- information-request
- mask-reply
- mask-request
- mobile-redirect
- net-redirect
- net-tos-redirect
- net-tos-unreachable
- net-unreachable
- network-unknown
- no-room-for-option
- option-missing
- packet-too-big
- parameter-problem
- port-unreachable
- precedence-unreachable
- protocol-unreachable
- redirect
- device-advertisement
- device-solicitation
- source-quench
- source-route-failed
- time-exceeded
- timestamp-reply

- timestamp-request
- ttl-exceeded
- unreachable

The TCP ports are as follows. A port can be specified by port name and port number:

- bgp
- chargen
- cmd
- daytime
- discard
- domain
- echo
- exec
- finger
- ftp
- ftp-data
- gopher
- hostname
- ident
- irc
- klogin
- kshell
- ldp
- login
- nntp
- pim-auto-rp
- pop2
- pop3
- smtp
- sunrpc
- syslog
- tacacs
- talk
- telnet
- time
- uucp
- whois
- www

The UDP ports are as follows. A UDP port can be specified by port name and port number.

- biff
- bootpc
- bootps
- discard

- dnsix
- domain
- echo
- isakmp
- mobile-ip
- nameserver
- netbios-dgm
- netbios-ns
- netbios-ss
- ntp
- pim-auto-rp
- rip
- snmp
- snmptrap
- sunrpc
- syslog
- tacacs
- talk
- tftp
- time
- who
- xdmcp

The Ethernet types are as below:

- aarp
- appletalk
- decnet-iv
- diagnostic
- etype-6000
- etype-8042
- lat
- lavc-sca
- mop-console
- mop-dump
- mumps
- netbios
- vines-echo
- xns-idp

The UDF headers are as below:

- I2-head
- I3-head
- I4-head
- I5-head

Run **no {sn | permit | deny}** in ACL mode to delete ACEs.

**Configuration** 1. Example of the standard IP ACL

**Examples** The following basic IP ACL allows the packets whose source IP addresses are 192.168.1.64 - 192.168.1.127 to pass:

```
Ruijie (config)#access-list 1 permit 192.168.1.64 0.0.0.63
```

2. Example of the extended IP ACL

The following extended IP ACL allows the DNS messages and ICMP messages to pass:

```
Ruijie(config)#access-list 102 permit tcp any any eq domain log
Ruijie(config)#access-list 102 permit udp any any eq domain log
Ruijie(config)#access-list 102 permit icmp any any echo log
Ruijie(config)#access-list 102 permit icmp any any echo-reply
```

3. Example of the extended MAC ACL

This example shows how to deny the host with the MAC address 00d0f8000c0c to provide service with the protocol type 100 on gigabit Ethernet port 1/1. The configuration procedure is as below:

```
Ruijie(config)#access-list 702 deny host 00d0f8000c0c any aarp
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if)# mac access-group 702 in
```

4. Example of the extended expert ACL

The following example shows how to create and display an extended expert ACL. This expert ACL denies all the TCP packets with the source IP address 192.168.12.3 and the source MAC address 00d0.f800.0044.

```
Ruijie(config)#access-list 2702 deny tcp host 192.168.12.3 mac 00d0.f800.0044
any any
Ruijie(config)# access-list 2702 permit any any any any
Ruijie(config)# show access-lists
expert access-list extended 2702
10 deny tcp host 192.168.12.3 mac 00d0.f800.0044 any any
10 permit any any any any
```

|-------------------|----------------------------------------------|
| show access-lists | Show all the ACLs.                           |
| mac access-group  | Apply the extended MAC ACL on the interface. |

**Platform** N/A

**Description**

## 1.3 access-list list-remark

Use this command to write a helpful comment (remark) for an access list. Use the **no** form of this command to remove the remark.

**access-list** *id* **list-remark** *text*

**no access-list** *id* **list-remark**

| Parameter Description | Parameter   | Description                                                                                                                                                                         |
|-----------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>id</i>   | Access list number.<br>Standard IP ACL: 1 to 99, 1300 to 1999.<br>Extended IP ACL: 100 to 199. 2000 to 2699.<br>Extended MAC ACL: 700 to 799.<br>Extended Expert ACL: 2700 to 2899. |
|                       | <i>text</i> | Comment that describes the access list.                                                                                                                                             |

**Defaults** The access lists have no remarks by default.

**Command Mode** Global configuration mode

**Usage Guide** You can use this command to write a helpful comment for a specified access list. If the specified access list does not exist, the command will create the access list, then add remarks for the access list.

**Configuration Examples** The following example writes a comment of “this acl is to filter the host 192.168.4.12” for ACL100.

```
Ruijie(config)# ip access-list extended 100
Ruijie(config)# access-list 100 list-remark this acl is to filter the host
192.168.4.12
```

|------------------|-------------------------------|--------------------------------------------------------------------------------------------|
|                  | show access- lists            | Displays all access lists, including the remarks for the access lists.                     |
|                  | show access-lists <i>id</i>   | Displays the access list of a specified number, including the remarks for the access list. |
|                  | show access-lists <i>name</i> | Displays the access list of a specified name, including the remarks for the access list.   |

**Platform Description**

## 1.4 access-list remark

Use this command to write a helpful comment (remark) for an entry in a numbered access list. Use the **no** form of this command to remove the remark.

**access-list** *id* **remark** *text*

**no access-list** *id* **remark** *text*

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|             |                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>id</i>   | Access list number.<br>Standard IP ACL: 1 to 99, 1300 to 1999.<br>Extended IP ACL: 100 to 199. 2000 to 2699.<br>Extended MAC ACL: 700 to 799.<br>Extended Expert ACL: 2700 to 2899. |
| <i>text</i> | Comment that describes the access list entry.                                                                                                                                       |

**Defaults** The access list entries have no remarks by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** You can use this command to write a helpful comment for an entry in a specified access list. If the specified access list does not exist, the command will create the access list, then add remarks for the access entry.

**Configuration** The following example writes a comment for an entry in ACL102.

**Examples** Ruijie(config)# access-list 102 remark deny-host-10.1.1.1

|-------------------------------|--------------------------------------------------------------------------------------------------|
| show access-lists             | Displays all access lists, including the remarks for the access list entries.                    |
| show access-lists <i>id</i>   | Displays the access list of a specified number, including the remarks for the access list entry. |
| show access-lists <i>name</i> | Displays the access list of a specified name, including the remarks for the access list entry.   |

**Platform**

**Description**

## 1.5 clear counters access-list

Use this command to clear counters of packets matching ACLs.

**clear counters access-list** [*id* | *name* ]

**Parameter  
Description**

| Parameter   | Description        |
|-------------|--------------------|
| <i>id</i>   | Access list number |
| <i>name</i> | Access list name   |

**Defaults**

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** This command is used to clear the counters of packets matching the specified or all ACLs.

**Configuration** The following example clears the packet matching counter of ACL No. 2700:

**Examples**

```
Ruijie #show access-lists 2700
expert access-list extended 2700
    10 permit ip VID 4 host 192.168.3.55 any host 192.168.99.6 any (88 matches)
    20 deny tcp any any eq login any any (33455 matches)
    30 permit tcp any any host 192.168.6.9 any (10 matches)

Ruijie# clear counters access-list 2700
Ruijie #show access-lists 2700
expert access-list extended 2700
    10 permit ip VID 4 host 192.168.3.55 any host 192.168.99.6 any
    20 deny tcp any any eq login any any
    30 permit tcp any any host 192.168.6.9 any
```

**Related  
Commands**

|--------------------|------------------------------|
| expert access-list | Defines an expert ACL.       |
| deny               | Defines a deny ACL entry.    |
| permit             | Defines a permits ACL entry. |

**Platform** N/A

**Description**

## 1.6 clear access-list counters

Use this command to clear counters of packets matching the deny entries in ACLs.

**clear access-list counters** [*id* | *name*]

**Parameter  
Description**

| Parameter   | Description        |
|-------------|--------------------|
| <i>id</i>   | Access list number |
| <i>name</i> | Access list name   |

**Defaults**

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** This command is used to clear the counters of packets matching the deny entries in ACLs.

**Configuration** The following example clears the packet matching counter of ACL No. 1:

**Examples** Before configuration:

```
Ruijie #show access-lists
ip access-list standard 1
  10 deny host 50.1.1.2 (10 matches)
  20 permit host 60.1.1.2 (15 matches)
  (10 packets filtered)
```

After configuration:

```
Ruijie# end
Ruijie# clear access-list counters
Ruijie# show access-lists
ip access-list standard 1
  10 deny host 50.1.1.2 (10 matches)
  20 permit host 60.1.1.2 (15 matches)
```

**Related  
Commands**

| Command            | Description                  |
|--------------------|------------------------------|
| expert access-list | Defines an expert ACL.       |
| deny               | Defines a deny ACL entry.    |
| permit             | Defines a permits ACL entry. |

**Platform** N/A

**Description**

## 1.7 deny

One or multiple **deny** conditions are used to determine whether to forward or discard the packet. In ACL configuration mode, you can modify the existent ACL or configure according to the protocol details.

### 1. Standard IP ACL

```
[sn] deny {source source-wildcard | host source | any} interface idx [{time-range tm-range-name}]
[ log ]
```

### 2. Extended IP ACL

```
[ sn ] deny protocol source source-wildcard destination destination-wildcard [ [precedence
precedence ] [ tos tos ] | [dscp dscp] [ecn ecn] ] [ fragment ] [ range lower upper ] [ time-range
time-range-name ] [ log ]
```

Extended IP ACLs of some important protocols:

- Internet Control Message Prot (ICMP)

```
[sn] deny icmp {source source-wildcard | host source | any} {destination destination-wildcard |
```

**host** *destination* | **any** [*icmp-type*] [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [**precedence** *precedence*] [**tos** *tos*] [**fragment**] [**time-range** *time-range-name*]

- Transmission Control Protocol (TCP)

[ *sn* ] **deny tcp** { *source* *source-wildcard* | **host** *Source* | **any** } { *destination* *destination-wildcard* | **host** *destination* | **any** } [ [**precedence** *precedence*] [ **tos** *tos*] | [**dscp** *dscp*]] [ **fragment**] [ **range** *lower upper*] [ **time-range** *time-range-name*] [ **match-all** *tcp-flag* | **established** ]

- User Datagram Protocol (UDP)

[ *sn* ] **deny udp** { *source* *source-wildcard* | **host** *source* | **any** } [ { *destination* *destination-wildcard* | **host** *destination* | **any** } ] [ [**precedence** *precedence*] [ **tos** *tos*] | [**dscp** *dscp*]] [ **fragment**] [ **range** *lower upper*] [ **time-range** *time-range-name* ]

### 3. Extended MAC ACL

[ *sn* ] **deny** { **any** | **host** *source-mac-address* } { **any** | **host** *destination-mac-address* } [ *ethernet-type* ] [ **cos** [ *out*] ] [ **inner** *in* ] ]

### 4. Extended expert ACL

[ *sn* ] **deny** [ *protocol* | [ *ethernet-type*] [ **cos** [ *out*] ] [ **inner** *in* ] ] ] [ [ **VID** [ *out*] ] [ **inner** *in* ] ] ] { *source* *source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination* *destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ [**precedence** *precedence*] [ **tos** *tos*] | [**dscp** *dscp*]] [ **fragment**] [ **range** *lower upper*] [ **time-range** *time-range-name* ]

- When you select the ethernet-type field or cos field:

[ *sn* ] **deny** [ [ *ethernet-type*] [ **cos** [ *out*] ] [ **inner** *in* ] ] ] [ [ **VID** [ *out*] ] [ **inner** *in* ] ] ] { *source* *source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination* *destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ **time-range** *time-range-name* ]

- When you select the protocol field:

[ *sn* ] **deny protocol** [ [ **VID** [ *out*] ] [ **inner** *in* ] ] ] { *source* *source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination* *destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ [**precedence** *precedence*] [ **tos** *tos*] | [**dscp** *dscp*]] [ **fragment**] [ **range** *lower upper*] [ **time-range** *time-range-name* ]

- Extended expert ACLs of some important protocols

### Internet Control Message Protocol (ICMP)

[ *sn* ] **deny icmp** [ [ **VID** [ *out*] ] [ **inner** *in* ] ] ] { *source* *source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination* *destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ *icmp-type*] [ [ *icmp-type* [*icmp-code*]] | [*icmp-message*] ] ] [ [**precedence** *precedence*] [ **tos** *tos*] | [**dscp** *dscp*]] [ **fragment**] [ **time-range** *time-range-name* ]

### Transmission Control Protocol (TCP)

[ *sn* ] **deny tcp** [ [ **VID** [ *out*] ] [ **inner** *in* ] ] ] { *source* *source-wildcard* | **host** *Source* | **any** } { **host** *source-mac-address* | **any** } { *destination* *destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ [**precedence** *precedence*] [ **tos** *tos*] | [**dscp** *dscp*]] [ **fragment**] [ **range** *lower upper*] [ **time-range** *time-range-name*] [ **match-all** *tcp-flag* | **established** ]

### User Datagram Protocol (UDP)

[ *sn* ] **deny udp** [ [ **VID** [ *out*] ] [ **inner** *in* ] ] ] { *source* *source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination* *destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ [**precedence** *precedence*] [ **tos** *tos*] | [**dscp** *dscp*]] [ **fragment**] [ **range** *lower upper*] [ **time-range** *time-range-name* ]

**Address Resolution Protocol (ARP)**

[sn] deny arp {vid vlan-id}[ host source-mac-address | any] [host destination-mac-address | any] {sender-ip sender-ip-wildcard | host sender-ip | any} {sender-mac sender-mac-wildcard | host sender-mac | any} {target-ip target-ip-wildcard | host target-ip | any}

## 5. Extended IPv6 ACL

[sn] deny protocol{source-ipv6-prefix/prefix-length | any | host source-ipv6-address } {destination-ipv6-prefix / prefix-length | any| hostdestination-ipv6-address} [dscp dscp] [flow-label flow-label] [fragment] [range lower upper] [time-range time-range-name]

Extended ipv6 ACLs of some important protocols:

**Internet Control Message Protocol (ICMP)**

[sn]deny icmp {source-ipv6-prefix / prefix-length | any source-ipv6-address | host} {destination-ipv6-prefix / prefix-length| host destination-ipv6-address | any} [icmp-type] [[icmp-type [icmp-code]] | [icmp-message]] [dscp dscp] [flow-label flow-label] [fragment] [time-range time-range-name]

**Transmission Control Protocol (TCP)**

[ sn ] deny tcp { source-ipv6-prefix / prefix-length | hostsource-ipv6-address | any } { destination-ipv6-prefix /prefix-length | host destination-ipv6-address | any } ] [ dscp dscp ] [ flow-label flow-label ] [ fragment ] [ range lower upper ] [ time-range time-range-name ] [ match-all tcp-flag | established ]

**User Datagram Protocol (UDP)**

[ sn ] deny udp { source-ipv6-prefix/prefix-length | host source-ipv6-address | any } { destination-ipv6-prefix /prefix-length | host destination-ipv6-address | any } [ dscp dscp ] [ flow-label flow-label ] [ fragment ] [ range lower upper ] [ time-range time-range-name ]

**Parameter Description**

| Parameter                   | Description                                                                                                                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sn</i>                   | ACL entry sequence number                                                                                                                                                                                                                              |
| <b>deny</b>                 | If not matched, access is denied.                                                                                                                                                                                                                      |
| <i>source</i>               | Specify the source IP address (host address or network address).                                                                                                                                                                                       |
| <i>source-wildcard</i>      | It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                                                                      |
| <i>protocol</i>             | IP protocol number. It can be one of EIGRP, GRE, IPINIP, IGMP, NOS, OSPF, ICMP, UDP, TCP, and IP. It can also be a number representing the IP protocol between 0 and 255. The important protocols such as ICMP, TCP, and UDP are described separately. |
| <i>destination</i>          | Specify the destination IP address (host address or network address).                                                                                                                                                                                  |
| <i>destination-wildcard</i> | Wildcard of the destination IP address. It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                              |
| <b>fragment</b>             | Packet fragment filtering                                                                                                                                                                                                                              |
| <b>precedence</b>           | Specify the packet priority.                                                                                                                                                                                                                           |
| <i>precedence</i>           | Packet precedence value (0 to 7)                                                                                                                                                                                                                       |
| <b>range</b>                | Layer4 port number range of the packet.                                                                                                                                                                                                                |
| <i>lower</i>                | Lower limit of the layer4 port number.                                                                                                                                                                                                                 |
| <i>upper</i>                | Upper limit of the layer4 port number.                                                                                                                                                                                                                 |

|                                               |                                                                                         |
|-----------------------------------------------|-----------------------------------------------------------------------------------------|
| <b>time-range</b>                             | Time range of packet filtering                                                          |
| <i>time-range-name</i>                        | Time range name of packet filtering                                                     |
| <b>tos</b>                                    | Specify type of service.                                                                |
| <i>tos</i>                                    | ToS value (0 to 15)                                                                     |
| <i>icmp-type</i>                              | ICMP message type (0 to 255)                                                            |
| <i>icmp-code</i>                              | ICMP message type code (0 to 255)                                                       |
| <i>icmp-message</i>                           | ICMP message type name                                                                  |
| <b>host</b> <i>source-mac-address</i>         | Source physical address                                                                 |
| <b>host</b><br><i>destination-mac-address</i> | Destination physical address                                                            |
| <b>VID</b> <i>vid</i>                         | Match the specified VID.                                                                |
| <i>ethernet-type</i>                          | Ethernet type                                                                           |
| <b>match-all</b>                              | Match all the bits of the TCP flag.                                                     |
| <i>tcp-flag</i>                               | Match the TCP flag.                                                                     |
| <b>established</b>                            | Match the RST or ACK bits, not other bits of the TCP flag.                              |
| <i>source-ipv6-prefix</i>                     | Source IPv6 network address or network type                                             |
| <i>destination-ipv6-prefix</i>                | Destination IPv6 network address or network type                                        |
| <i>prefix-length</i>                          | Prefix mask length                                                                      |
| <i>source-ipv6-address</i>                    | Source IPv6 address                                                                     |
| <i>destination-ipv6-address</i>               | Destination IPv6 address                                                                |
| <b>dscp</b>                                   | Differential Service Code Point                                                         |
| <i>dscp</i>                                   | Code value, within the range of 0 to 63                                                 |
| <i>flow-label</i>                             | Flow label                                                                              |
| <i>flow-label</i>                             | Flow label value, within the range of 0 to 1048575.                                     |
| <i>protocol</i>                               | For the IPv6, the field can be ipv6   icmp   tcp   udp and number in the range 0 to 255 |
| <b>time-range</b>                             | Time range of the packet filtering                                                      |
| <i>time-range-name</i>                        | Time range name of the packet filtering                                                 |

**Defaults** No entry

**Command mode** ACL configuration mode.

**Usage Guide** Use this command to configure the filtering entry of ACLs in ACL configuration mode.

**Configuration Examples** The following example shows how to create and display an extended expert ACL. This expert ACL denies all the TCP packets with the source IP address 192.168.4.12 and the source MAC address 001300498272.

```
Ruijie(config)#expert access-list extended 2702
Ruijie(config-exp-nacl)#deny tcp host
192.168.4.12 host 0013.0049.8272 any any
Ruijie(config-exp-nacl)#permit any any any any
Ruijie(config-exp-nacl)#show access-lists
```

```
expert access-list extended 2702
10 deny tcp host 192.168.4.12 host 0013.0049.8272 any any
20 permit any any any any
Ruijie(config-exp-nacl)#
```

This example shows how to use the extended IP ACL. The purpose is to deny the host with the IP address 192.168.4.12 to provide services through the TCP port 100 and apply the ACL to Interface gigabitethernet 1/1. The configuration procedure is as below:

```
Ruijie(config)# ip access-list extended ip-ext-acl
Ruijie(config-ext-nacl)# deny tcp host 192.168.4.12 eq 100 any
Ruijie(config-ext-nacl)# show access-lists
ip access-list extended ip-ext-acl
10 deny tcp host 192.168.4.12 eq 100 any
Ruijie(config-ext-nacl)#exit
Ruijie(config)#interface gigabitethernet 1/1
Ruijie(config-if)#ip access-group ip-ext-acl in
Ruijie(config-if)#
```

This example shows how to use the extended MAC ACL. The purpose is to deny the host with the MAC address 0013.0049.8272 to send Ethernet frames of the type 100 and apply the rule to Interface gigabitethernet 1/1. The configuration procedure is as below:

```
Ruijie(config)#mac access-list extended mac1
Ruijie(config-mac-nacl)#deny host 0013.0049.8272 any aarp
Ruijie(config-mac-nacl)# show access-lists
mac access-list extended mac1
10 deny host 0013.0049.8272 any aarp
Ruijie(config-mac-nacl)#exit
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if)# mac access-group mac1 in
```

This example shows how to use the standard IP ACL. The purpose is to deny the host with the IP address 192.168.4.12 and apply the rule to Interface gigabitethernet 1/1. The configuration procedure is as below:

```
Ruijie(config)#ip access-list standard 34
Ruijie(config-ext-nacl)# deny host 192.168.4.12
Ruijie(config-ext-nacl)#show access-lists
ip access-list standard 34
10 deny host 192.168.4.12
Ruijie(config-ext-nacl)#exit
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if)# ip access-group 34 in
```

This example shows how to use the extended IPV6 ACL. The purpose is to deny the host with the IP address 192.168.4.12 and apply the rule to Interface gigabitethernet 1/1. The configuration procedure is as below:

```
Ruijie(config)#ipv6 access-list extended v6-acl
Ruijie(config-ipv6-nacl)#11 deny ipv6 host 192.168.4.12 any
Ruijie(config-ipv6-nacl)#show access-lists
```

```

ipv6 access-list extended v6-acl
11 deny ipv6 host 192.168.4.12 any
Ruijie(config-ipv6-nacl)# exit
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if)# ipv6 traffic-filter v6-acl in

```

#### Related Commands

| Command             | Description                                     |
|---------------------|-------------------------------------------------|
| show access-lists   | Displays all ACLs.                              |
| ipv6 traffic-filter | Applies the extended IPv6 ACL on the interface. |
| ip access-group     | Applies the IP ACL on the interface.            |
| mac access-group    | Applies the extended MAC ACL on the interface.  |
| ip access-list      | Defines an IP ACL.                              |
| mac access-list     | Defines an extended MAC ACL.                    |

| ipv6 access-list    | Defines an extended IPv6 ACL.                   |
| permit              | Permits the access.                             |

**Platform** N/A

#### Description

## 1.8 expert access-group

Use this command to apply the specified expert access list on the specified interface or globally. Use the **no** form of the command to remove the application.

**expert access-group** { *id* | *name* } { **in** | **out** }

**no expert access-group** { *id* | *name* } { **in** | **out** }

#### Parameter Description

| Parameter   | Description                              |
|-------------|------------------------------------------|
| <i>id</i>   | Expert access list number: 2700 to 2899  |
| <i>name</i> | Name of the expert access list           |
| <b>in</b>   | Specifies filtering on inbound packets.  |
| <b>out</b>  | Specifies filtering on outbound packets. |

**Defaults** No expert access list is applied on the interface or globally.

**Command mode** Global/Interface configuration mode.

**Usage Guide** This command is used to apply the specified access list globally or on the interface to control the input

and output data streams. Use the **show access-group** command to view the setting. Use the **expert access-group { id | name } { in | out } counter-only** command on the interface to only collect packet statistics and not filter packets.

**Configuration Examples** The following example shows how to apply the **access-list accept\_00d0f8xxxxxx** only to Gigabit interface 0/1:

```
Ruijie(config)# interface GigaEthernet 0/1
Ruijie(config-if)# expert access-group
accept_00d0f8xxxxxx_only in
```

The following example applies the ACL numbered 2700 on interface fastEthernet0/1 to collect statistics on incoming packets:

```
Ruijie(config)# interface fastEthernet 0/1
Ruijie(config-if-FastEthernet 0/1)#expert access-group 2700 in counter-only
```

**Related Commands**

| Command           | Description                     |
|-------------------|---------------------------------|
| show access-group | Displays the ACL configuration. |

**Platform Description** N/A

## 1.9 expert access-list advanced

Use this command to create an advanced expert access list and place the device in expert advanced access list configuration mode. Use the **no** form of this command to remove the advanced expert access list.

**expert access-list advanced name**

**no expert access-list advanced name**

**Parameter Description**

| Parameter   | Description                             |
|-------------|-----------------------------------------|
| <i>name</i> | Name of the advanced expert access list |

**Defaults** N/A

**Command mode** Global configuration mode

**Usage Guide** Use this command to create an advanced expert access list (namely, ACL80) to match your custom fields.

**Configuration Examples** The following example creates an advanced expert access list named adv-acl.

```
Ruijie(config)# expert access-list advanced adv-acl
Ruijie(config-exp-dacl)# show access-lists
```

```
expert access-list advanced adv-acl
```

**Related  
Commands**

| Command                       | Description                                   |
|-------------------------------|-----------------------------------------------|
| show access-lists             | Displays all access lists.                    |
| show access-lists <i>name</i> | Displays the access list of a specified name. |

**Platform** N/A  
**Description**

## 1.10 expert access-list extended

Use this command to create an extended expert access list. Use the **no** form of the command to remove the ACL.

**expert access-list extended** {*id* | *name*}

**no expert access-list extended** {*id* | *name*}

**Parameter  
Description**

| Parameter   | Description                                      |
|-------------|--------------------------------------------------|
| <i>id</i>   | Extended expert access list number: 2700 to 2899 |
| <i>name</i> | Name of the extended expert access list          |

**Defaults** N/A

**Command mode** Global configuration mode.

**Usage Guide** Use the **show access-lists** command to display the ACL configurations.

**Configuration** Create an extended expert ACL named exp-acl:

**Examples**

```
Ruijie(config)# expert access-list extended exp-acl
Ruijie(config-exp-nacl)# show access-lists expert access-list extended
exp-acl
Ruijie(config-exp-nacl)#
```

Create an extended expert ACL numbered 2704:

```
Ruijie(config)# expert access-list extended 2704
Ruijie(config-exp-nacl)# show access-lists access-list extended 2704
Ruijie(config-exp-nacl)#
```

**Related  
Commands**

| Command                  | Description                       |
|--------------------------|-----------------------------------|
| <b>show access-lists</b> | Displays the extended expert ACLs |

**Platform** N/A

**Description**

## 1.11 expert access-list counter

Use this command to enable the counter of packets matching the specified expert access list. Use the **no** form of this command to disable this function.

**expert access-list counter** { *id* | *name* }

**no expert access-list counter** { *id* | *name* }

**Parameter Description**

| Parameter   | Description                              |
|-------------|------------------------------------------|
| <i>id</i>   | Expert access list number: 2700 to 2899. |
| <i>name</i> | Name of the access list.                 |

**Defaults** The counter of the packets matching the expert access list is disabled.

**Command mode** Global configuration mode

**Usage Guide** Use this command to enable the counter of packets matching the specified expert access list, so that you can analyze the counters to learn whether the network is attacked by the illegal packets.

**Configuration Examples** The following example enables the counter of packets matching the extended expert access list named exp-acl:

```
Ruijie(config)# expert access-list counter exp-acl
Ruijie(config)# show access-lists
expert access-list extended exp-acl
 10 permit ip VID 4 host 192.168.3.55 any host 192.168.99.6 any (16 matches)
 20 deny tcp any any eq login any any (78 matches)
```

The following example disables the counter of packets matching the extended expert access list named exp-acl.

```
Ruijie(config)#no expert access-list counter exp-acl
Ruijie(config)# show access-lists
expert access-list extended 2700
 10 permit ip VID 4 host 192.168.3.55 any host 192.168.99.6 any
 20 deny tcp any any eq login any any
```

**Related Commands**

| Command           | Description                       |
|-------------------|-----------------------------------|
| show access-lists | Displays the extended expert ACL. |

**Platform** N/A

## Description

## 1.12 expert access-list new-fragment-mode

Use this command to switch the matching mode of fragmentation packets. Use the **no** form of this command to restore the default matching mode of fragmentation packets.

**expert access-list new-fragment-mode** { *id* | *name* }

**no expert access-list new-fragment-mode** { *id* | *name* }

### Parameter Description

| Parameter   | Description                              |
|-------------|------------------------------------------|
| <i>id</i>   | Expert access list number: 2700 to 2899. |
| <i>name</i> | Name of the expert access list.          |

### Defaults

Use the default matching mode of fragmentation packets. By default, if the access rule is tagged with fragment, it will match all packets except for the first fragmentation packet. If the access rule is not tagged with fragment, all packets including the first and all subsequent fragmentation packets will be matched.

### Command mode

Global configuration mode

### Usage Guide

Use this command to switch and control the matching mode of access rules to fragmentation packets.

### Configuration Examples

The following example switches the matching mode of fragmentation packets for the ACL 2700 from the default mode to a new matching mode:

```
Ruijie(config)#expert access-list new-fragment-mode 2700
```

### Related Commands

| Command | Description |
|---------|-------------|
| -       | -           |

### Platform

### Description

## 1.13 expert access-list resequence

Use this command to resequence an expert access list. Use the **no** form of this command to restore the default order of access entries.

**expert access-list resequence** { *id* | *name* } *start-sn inc-sn*

**no expert access-list resequence** { *id* | *name* }

### Parameter

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

| Description     |                                                          |
|-----------------|----------------------------------------------------------|
| <i>id</i>       | Expert access list number: 2700 to 2899.                 |
| <i>name</i>     | Name of the expert access list                           |
| <i>start-sn</i> | Start sequence number. Range: 1 to 2147483647            |
| <i>inc-sn</i>   | Increment of the sequence number. Range: 1 to 2147483647 |

**Defaults**      *start-sn*: 10  
*inc-sn*: 10

**Command mode**      Global configuration mode

**Usage Guide**      Use this command to change the order of the access entries.

**Configuration**      The following example resequences entries of expert access list “exp-acl”:

**Examples**      Before the configuration:

```
Ruijie# show access-lists
expert access-list extended exp-acl
 10 permit ip any any any any
 20 deny ip any any any any
```

After the configuration:

```
Ruijie# config
Ruijie(config)# expert access-list resequence exp-acl 21 43
Ruijie(config)# exit
Ruijie# show access-lists
expert access-list extended exp-acl
 21 permit ip any any any any
 64 deny ip any any any any
```

**Related Commands**

**Description**

## 1.14 global access-group

Use this command to apply the global access list on the interface. Use the **no** form of this command to remove the global access list from the interface.

**global access-group**  
**no global access-group**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** By default, the global access list is applied on the interface.

**Command mode** Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example applies the global access list on interface fastEthernet0/0.

**Examples**

```
Ruijie(config)# interface fastEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#global access-group
```

| Related Commands | Command | Description |

## 1.15 ip access-group

Use this command to apply a specific access list globally or to an interface. Use the **no** form of this command to remove the access list from the interface.

**ip access-group** {*id* | *name*} {**in** | **out**}

**no ip access-group** { *id* | *name*} {**in** | **out**}

| Parameter Description | Parameter   | Description                                                                 |
|-----------------------|-------------|-----------------------------------------------------------------------------|
|                       | <i>id</i>   | IP access list or extended IP access list number:<br>1 to 199, 1300 to 2699 |
|                       | <i>name</i> | Name of the IP ACL                                                          |
|                       | in          | Filters the incoming packets of the interface.                              |
|                       | out         | Filters the outgoing packets of the interface.                              |

**Defaults** No access list is applied globally or on the interface by default.

**Command mode** Global, interface

**Usage Guide** Use this command to control access to a specified interface, VXLAN or globally.

**Configuration** The following example applies the ACL 120 on interface fastEthernet0/0 to filter the incoming packets:

**Examples**

```
Ruijie(config)# interface fastEthernet 0/0
Ruijie(config-if)# ip access-group 120 in
```

**Related Commands**

| Command           | Description        |
|-------------------|--------------------|
| access-list       | Defines an ACL.    |
| show access-lists | Displays all ACLs. |

**Platform** N/A

**Description**

## 1.16 ip access-list

Use this command to create a standard IP access list or extended IP access list. Use the **no** form of the command to remove the access list.

**ip access-list** {**extended** | **standard**} {*id* | *name*}

**no ip access-list** {**extended** | **standard**} {*id* | *name*}

**Parameter Description**

| Parameter   | Description                                                                                    |
|-------------|------------------------------------------------------------------------------------------------|
| <i>id</i>   | Access list number:<br>Standard: 1 to 99, 1300 to 1999;<br>Extended: 100 to 199, 2000 to 2699. |
| <i>name</i> | Name of the access list                                                                        |

**Defaults** N/A

**Command mode** Global configuration mode

**Usage Guide** Configure a standard access list if you need to filter on source address only. If you want to filter on anything other than source address, you need to create an extended access list. Refer to **deny** or **permit** in the two modes. Use the **show access-lists** command to display the ACL configurations.

**Configuration** The following example creates a standard access list named std-acl.

**Examples**

```
Ruijie(config)# ip access-list standard std-acl
Ruijie(config-std-nacl)# show access-lists
ip access-list standard std-acl
Ruijie(config-std-nacl)#
```

The following example creates an extended ACL numbered 123:

```
Ruijie(config)# ip access-list extended 123
Ruijie(config-ext-nacl)# show access-lists
ip access-list extended 123
```

#### Related Commands

|-------------------|--------------------|
| show access-lists | Displays all ACLs. |

**Platform** N/A  
**Description**

## 1.17 ip access-list log-update interval

Use this command to configure the interval at which the IPv4 access list log is updated. Use the **no** form of this command to restore the default interval.

**ip access-list log-update interval** *time*

**no ip access-list log-update interval**

#### Parameter Description

| Parameter   | Description                                                                                                                                                                                                                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>time</i> | For the access rule with the <b>log</b> option, a packet hit is output at the interval of ACL logging output. The interval ranges from 0 to 1440 minutes, and the default value is 5 minutes, indicating that the ACL matching log of a specified flow is output every 5 minutes. 0 indicates that no ACL logging is output. |

**Defaults** The default interval at which the IPv4 access list log is updated is 5 minutes.

**Command mode** Global configuration mode

**Usage Guide** Use this command to configure the interval at which the IPv4 access list log is updated.

**Configuration Examples** The following example configures the interval for the IPv4 access list log update to 10 minutes:

#### Examples

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# ip access-list log-update interval 10
```

## 1.18 ip access-list counter

Use this command to enable the counter of packets matching the standard or extended IP access list. Use the **no** form of this command to disable the counter.

**ip access-list counter** { *id* | *name* }

**no ip access-list counter** { *id* | *name* }

| Parameter Description | Parameter   | Description                                                                                                                     |
|-----------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>id</i>   | IP access list number:<br>Standard IP access list: 1 to 99, 1300 to 1999;<br>Extended IP access list: 100 to 199, 2000 to 2699. |
|                       | <i>name</i> | Name of the IP access list.                                                                                                     |

**Defaults** The counter of packets matching the standard or extended IP access list is disabled by default.

**Command mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables the counter of packets matching the standard access list:

```
Ruijie(config)# ip access-list counter std-acl
Ruijie(config-std-nacl)# show access-lists
ip access-list standard std-acl
 10 permit 195.168.6.0 0.0.0.255 (999 matches)
 20 deny host 5.5.5.5 time-range tm (2000 matches)
```

The following example disables the counter of packets matching the standard access list:

```
Ruijie(config)#no ip access-list counter std-acl
Ruijie(config-std-nacl)# show access-lists
ip access-list standard std-acl
 10 permit 195.168.6.0 0.0.0.255
 20 deny host 5.5.5.5 time-range tm
```

| Related Commands | Command           | Description                |
|------------------|-------------------|----------------------------|
|                  | show access-lists | Displays all access lists. |

**Platform**  
**Description** N/A

## 1.19 ip access-list new-fragment-mode

Use this command to switch the matching mode of fragmentation packets of standard or extended IP access list. Use the **no** form of this command to restore the default matching mode of fragmentation packets.

**ip access-list new-fragment-mode** { *id* | *name* }

**no ip access-list new-fragment-mode** { *id* | *name* }

| Parameter Description | Parameter   | Description                                                                                                                     |
|-----------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>id</i>   | IP access list number:<br>Standard IP access list: 1 to 99, 1300 to 1999;<br>Extended IP access list: 100 to 199, 2000 to 2699. |
|                       | <i>name</i> | Name of the standard or extended IP access list                                                                                 |

**Defaults** Use the default matching mode of fragmentation packets. By default, if the access rule is tagged with fragment, it will match all packets except for the first fragmentation packet. If the access rule is not tagged with fragment, all packets including the first and all subsequent fragmentation packets will be matched.

**Command mode** Global configuration mode

**Usage Guide** This command is used to switch and control the fragmentation packet matching mode of access rules.

**Configuration Examples** The following example switches the fragmentation packet matching mode of the ACL 100 from the default mode to a new mode:

```
Ruijie(config)#ip access-list new-fragment-mode 100
```

| Related Commands | Command | Description |

**Description** N/A

## 1.20 ip access-list resequence

Use this command to resequence a standard or extended IP access list. Use the **no** form of this

command to restore the default order of access entries.

**ip access-list resequence** { *id* | *name* } *start-sn* *inc-sn*

**no ip access-list resequence** { *id* | *name* }

| Parameter Description | Parameter       | Description                                                                                                                     |
|-----------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>id</i>       | IP access list number:<br>Standard IP access list: 1 to 99, 1300 to 1999;<br>Extended IP access list: 100 to 199, 2000 to 2699. |
|                       | <i>name</i>     | Name of the standard or extended IP access list                                                                                 |
|                       | <i>start-sn</i> | Start sequence number. Range: 1 to 2147483647                                                                                   |
|                       | <i>inc-sn</i>   | Increment of the sequence number. Range: 1 to 2147483647                                                                        |

**Defaults**      *start-sn*: 10  
                  *inc-sn*: 10

**Command mode**      Global configuration mode

**Usage Guide**      Use this command to change the order of the access entries.

**Configuration Examples**      The following example resequences entries of ACL1:

**Examples**      Before the configuration:

```
Ruijie# show access-lists
ip access-list standard 1
10 permit host 192.168.4.12
20 deny any any
```

After the configuration:

```
Ruijie# config
Ruijie(config)# ip access-list resequence 1 21 43
Ruijie(config)# exit
Ruijie# show access-lists
ip access-list standard 1
21 permit host 192.168.4.12
64 deny any any
```

|------------------|-------------------|-----------------------------|
|                  | show access-lists | Displays all access lists.. |

**Platform Description**      N/A

## 1.21 ipv6 access-list

Use this command to create an IPv6 access list and to place the device in IPv6 access list configuration mode. Use the **no** form of this command to remove the access list.

**ipv6 access-list** *name*

**no ipv6 access-list** *name*

| Parameter Description | Parameter   | Description                   |
|-----------------------|-------------|-------------------------------|
|                       | <i>name</i> | Name of the IPv6 access list. |

**Defaults** N/A

**Command mode** Global configuration mode

**Usage Guide** To filter the IPv6 packets through the access list, you need to define an IPv6 access list by using the **ipv6 access-list** command.

**Configuration** The following example creates an IPv6 access list named v6-acl:

**Examples**

```
Ruijie(config)# ipv6 access-list v6-acl
Ruijie(config-ipv6-nacl)# show access-lists
ipv6 access-list extended v6-acl
Ruijie(config-ipv6-nacl)#
```

| Related Commands | Command           | Description                |
|------------------|-------------------|----------------------------|
|                  | show access-lists | Displays all access lists. |

**Platform** N/A

**Description**

## 1.22 ipv6 access-list counter

Use this command to enable the counter of packets matching the IPv6 access list. Use the **no** form of this command to disable the counter.

**ipv6 access-list counter** *name*

**no ipv6 access-list counter** *name*

| Parameter Description | Parameter   | Description                   |
|-----------------------|-------------|-------------------------------|
|                       | <i>name</i> | Name of the IPv6 access list. |

|                     |                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b>     | -                                                                                                                                   |
| <b>Command mode</b> | Global configuration mode                                                                                                           |
| <b>Usage Guide</b>  | Use this command to enable the counter of packets matching the IPv6 access list to monitor the IPv6 packets matching and filtering. |

**Configuration** The following example enables the counter of packets matching the IPv6 access list named v6-acl:

**Examples**

```
Ruijie(config)# ipv6 access-list v6-acl
Ruijie(config-ipv6-nacl)# show access-lists
ipv6 access-list acl-v6
 10 permit icmp any any (7 matches)
 20 deny tcp any any (7 matches)
```

The following example disables the counter of packets matching the IPv6 access list named v6-acl:

```
Ruijie(config)#no ipv6 access-list v6-acl counter
Ruijie(config-ipv6-nacl)# show access-lists
ipv6 access-list acl-v6
 10 permit icmp any any
 20 deny tcp any any
```

**Related Commands**

| Command           | Description                |
|-------------------|----------------------------|
| show access-lists | Displays all access lists. |

**Platform** N/A  
**Description**

## 1.23 ipv6 access-list log-update interval

Use this command to configure the interval at which the IPv6 access list log is updated. Use the **no** form of this command to restore the default interval.

**ipv6 access-list log-update interval** *time*

**no ipv6 access-list log-update interval**

**Parameter Description**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>time</i> | For the access rule with the <b>logging</b> option, a packet hit is output at the interval of ACL logging output. The interval ranges from 0 to 1440 minutes, and the default value is 5 minutes, indicating that the ACL matching log of a specific flow is output every 5 minutes. 0 indicates that no ACL logging is output. |

**Defaults** By default, the value is 5 minutes.

**Command mode** Global configuration mode

**Usage Guide** Use this command to configure the interval at which the IPv6 access list log is updated.

**Configuration Examples** The following example configures the interval for the IPv6 access list log update to 10 minutes:

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)# ipv6 access-list log-update interval 9
```

**Related Commands**

| Command          | Description                                        |
|------------------|----------------------------------------------------|
| ipv6 access-list | Defines an IPv6 access list.                       |
| deny             | Defines the <b>deny</b> access entries.            |
| permit           | Defines the <b>permit</b> access entries.          |
| show running     | Displays the running configurations of the device. |

**Platform Description** N/A

## 1.24 ipv6 access-list resequence

Use this command to resequence an IPv6 access list. Use the **no** form of this command to restore the default order of access entries.

**ipv6 access-list resequence** *name start-sn inc-sn*

**no ipv6 access-list resequence** *name*

**Parameter Description**

| Parameter       | Description                                              |
|-----------------|----------------------------------------------------------|
| <i>name</i>     | Name of the IPv6 access list                             |
| <i>start-sn</i> | Start sequence number. Range: 1 to 2147483647            |
| <i>inc-sn</i>   | Increment of the sequence number. Range: 1 to 2147483647 |

**Defaults** *start-sn*: 10  
*inc-sn*: 10

**Command mode** Global configuration mode

**Usage Guide** Use this command to change the order of the access entries.

**Configuration** The following example resequences entries of IPv6 access list "v6-acl":

**Examples** Before the configuration:

```
Ruijie# show access-lists
ipv6 access-list v6-acl
 10 permit ipv6 any any
 20 deny ipv6 any any
```

After the configuration:

```
Ruijie# config
Ruijie(config)# ipv6 access-list resequence v6-acl 21 43
Ruijie(config)# exit
Ruijie# show access-lists
ipv6 access-list v6-acl
 21 permit ipv6 any any
 64 deny ipv6 any any
```

**Related  
Commands**

| Command           | Description                 |
|-------------------|-----------------------------|
| show access-lists | Displays all access lists.. |

**Platform** N/A

**Description**

## 1.25 ipv6 traffic-filter

Use this command to apply an IPv6 access list on the specified interface/VXLAN. Use the **no** form of the command to remove the IPv6 access list from the interface.

**ipv6 traffic-filter** *name* { **in** | **out** }

**no ipv6 traffic-filter** *name* { **in** | **out** }

**Parameter  
Description**

| Parameter   | Description                             |
|-------------|-----------------------------------------|
| <i>name</i> | Name of IPv6 access list                |
| in          | Specifies filtering on inbound packets  |
| out         | Specifies filtering on outbound packets |

**Defaults** N/A

**Command  
mode** Interface configuration mode.

**Usage Guide** Use this command to apply the IPv6 access list to a specified interface to filter the inbound or outbound packets.

**Configuration** The following example applies the IPv6 access list named **v6-acl** to interface GigabitEthernet 0/1:

**Examples**

```
Ruijie(config)# interface GigaEthernet 0/1
Ruijie(config-if)# ipv6 traffic-filter v6-acl in
```

**Related  
Commands**

| Command           | Description                                   |
|-------------------|-----------------------------------------------|
| show access-group | Displays ACL configurations on the interface. |

**Platform** N/A

**Description**

## 1.26 list-remark

Use this command to write a helpful comment (remark) for an access list. Use the **no** form of this command to remove the remark.

**list-remark** *text*

**no list-remark**

**Parameter  
Description**

| Parameter   | Description                             |
|-------------|-----------------------------------------|
| <i>text</i> | Comment that describes the access list. |

**Defaults** The access lists have no remarks by default.

**Command  
mode** ACL configuration mode

**Usage Guide** You can use this command to write a helpful comment for a specified access list.

**Configuration** The following example writes a comment of “this acl is to filter the host 192.168.4.12” for ACL102.

**Examples**

```
Ruijie(config)# ip access-list extended 102
Ruijie(config-ext-nacl)# list-remark this acl is to filter the host
192.168.4.12
Ruijie(config-ext-nacl)# show access-lists
ip access-list extended 102
deny ip host 192.168.4.12 any
1000 hits
this acl is to filter the host 192.168.4.12
Ruijie(config-ext-nacl)#
```

**Related  
Commands**

| Command           | Description                  |
|-------------------|------------------------------|
| show access-lists | Displays all access lists.   |
| ip access-list    | Defines an IPv4 access list. |

|                         |                                                                         |
|-------------------------|-------------------------------------------------------------------------|
| access-list list remark | Adds a helpful comment for an access list in global configuration mode. |
|-------------------------|-------------------------------------------------------------------------|

**Platform** N/A

**Description**

## 1.27 mac access-group

Use this command to apply the specified MAC access list globally or on the specified interface.. Use the **no** form of the command to remove the access list from the interface.

**mac access-group** { *id* | *name* } { **in** | **out** }

**no mac access-group** { *id* | *name* } { **in** | **out** }

**Parameter Description**

| Parameter   | Description                                           |
|-------------|-------------------------------------------------------|
| <i>id</i>   | MAC access list number. The range is from 700 to 799. |
| <i>name</i> | Name of the MAC access list                           |
| in          | Specifies filtering on the inbound packets.           |
| out         | Specifies filtering on the outbound packets.          |

**Defaults** No MAC access list is applied by default.

**Command mode** Global/Interface configuration mode.

**Usage Guide** Use this command to apply the access list globally or to the interface to filter the inbound or outbound packets based on the MAC address.

**Configuration Examples** The following example applies the MAC access-list **accept\_00d0f8xxxxxx\_only** to interface GigabitEthernet 1/1:

```
Ruijie(config)# interface GigaEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# mac access-group
accept_00d0f8xxxxxx_only in
```

**Related Commands**

| Command           | Description                                      |
|-------------------|--------------------------------------------------|
| show access-group | Displays the ACL configuration on the interface. |

**Platform** N/A

**Description**

## 1.28 mac access-list extended

Use this command to create an extended MAC access list. Use the **no** form of the command to remove the MAC access list.

**mac access-list extended** { *id* | *name* }

**no mac access-list extended** { *id* | *name* }

| Parameter Description | Parameter   | Description                                                    |
|-----------------------|-------------|----------------------------------------------------------------|
|                       | <i>id</i>   | Extended MAC access list number. The range is from 700 to 799. |
|                       | <i>name</i> | Name of the extended MAC access list                           |

**Defaults** N/A

**Command mode** Global configuration mode.

**Usage Guide** To filter the packets based on the MAC address, you need to define a MAC access list by using the **mac access-list extended** command.

**Configuration Examples** The following command creates an extended MAC access list named mac-acl:

```
Ruijie(config)# mac access-list extended mac-acl
```

```
Ruijie(config-mac-nacl)# show access-lists mac access-list extended mac-acl
```

The following command creates an extended MAC access list numbered 704:

```
Ruijie(config)# mac access-list extended 704
```

```
Ruijie(config-mac-nacl)# show access-lists mac access-list extended 704
```

| Related Commands | Command           | Description                |
|------------------|-------------------|----------------------------|
|                  | show access-lists | Displays all access lists. |

**Platform** N/A

**Description**

## 1.29 mac access-list counter

Use this command to enable the counter of packet matching the extended MAC access list. Use the **no** form of this command to disable the counter.

**mac access-list counter** { *id* | *name* }

**no mac access-list counter** { *id* | *name* }

| Parameter Description | Parameter | Description                                                    |
|-----------------------|-----------|----------------------------------------------------------------|
|                       | <i>id</i> | Extended MAC access list number. The range is from 700 to 799. |

|             |                                      |
|-------------|--------------------------------------|
| <i>name</i> | Name of the extended MAC access list |
|-------------|--------------------------------------|

**Defaults** The counter is disabled by default.

**Command mode** Global configuration mode

**Usage Guide** Use this command to enable the counter of packets matching the MAC access list to monitor the packets matching and filtering.

**Configuration Examples** The following example enables the counter of packet matching the extended MAC access list named mac-acl:

```
Ruijie(config)# mac access-list counter mac-acl
Ruijie(config)# show access-lists
mac access-list extended mac-acl
 10 permit host 0023.56ac.8965 any (170 matches)
 20 deny any any etype-any cos 6 (239 matches)
```

The following example disables the counter of packet matching the extended MAC access list named mac-acl:

```
Ruijie(config)#no mac access-list counter mac-acl
Ruijie(config)# show access-lists
mac access-list extended mac-acl
 10 permit host 0023.56ac.8965 any
 20 deny any any etype-any cos 6
```

**Related Commands**

| Command           | Description                |
|-------------------|----------------------------|
| show access-lists | Displays all access lists. |

**Platform Description** N/A

## 1.30 mac access-list resequence

Use this command to resequence an extended MAC access list. Use the **no** form of this command to restore the default order of access entries.

**mac access-list resequence** { *id* | *name* } *start-sn inc-sn*

**no mac access-list resequence** { *id* | *name* }

**Parameter Description**

| Parameter   | Description                                  |
|-------------|----------------------------------------------|
| <i>id</i>   | Extended MAC access list number: 700 to 799. |
| <i>name</i> | Name of the extended MAC access list         |

|                 |                                                          |
|-----------------|----------------------------------------------------------|
| <i>start-sn</i> | Start sequence number. Range: 1 to 2147483647            |
| <i>inc-sn</i>   | Increment of the sequence number. Range: 1 to 2147483647 |

**Defaults**      *start-sn*: 10  
*inc-sn*: 10

**Command mode**      Global configuration mode

**Usage Guide**      Use this command to change the order of the access entries.

**Configuration**      The following example resequences entries of extended MAC access list "mac-acl":

**Examples**      Before the configuration:

```
Ruijie# show access-lists
mac access-list extended mac-acl
 10 permit any any etype-any
 20 deny any any etype-any
```

After the configuration:

```
Ruijie# config
Ruijie(config)# mac access-list resequence exp-acl 21 43
Ruijie(config)# exit
Ruijie# show access-lists
mac access-list extended mac-acl
 21 permit any any etype-any
 64 deny any any etype-any
```

**Related Commands**

| Command           | Description                 |
|-------------------|-----------------------------|
| show access-lists | Displays all access lists.. |

**Platform**      N/A

**Description**

## 1.31 permit

One or multiple **permit** conditions are used to determine whether to forward or discard the packet. In ACL configuration mode, you can modify the existent ACL or configure according to the protocol details.

1. Standard IP ACL

```
[ sn ] permit {source source-wildcard | host source | any | interface idx } [ time-range tm-range-name] [ log ]
```

2. Extended IP ACL

```
[ sn ] permit protocol source source-wildcard destination destination-wildcard [ [precedence
```

*precedence* ] [ **tos** *tos* ] | [ **dscp** *dscp* ] ] [ **fragment** ] [ **range** *lower upper* ] [ **time-range** *time-range-name* ] [ **log** ]

Extended IP ACLs of some important protocols:

Internet Control Message Protocol (ICMP)

[ *sn* ] **permit icmp** { *source source-wildcard* | **host** *source* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } [ *icmp-type* ] [ [ *icmp-type* [ *icmp-code* ] ] ] [ *icmp-message* ] ] [ [ **precedence** *precedence* ] [ **tos** *tos* ] | [ **dscp** *dscp* ] ] [ **fragment** ] [ **time-range** *time-range-name* ]

Transmission Control Protocol (TCP)

[ *sn* ] **permit tcp** { *source source-wildcard* | **host** *Source* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } ] [ [ **precedence** *precedence* ] [ **tos** *tos* ] | [ **dscp** *dscp* ] ] [ **fragment** ] [ **range** *lower upper* ] [ **time-range** *time-range-name* ] [ **match-all** *tcp-flag* | **established** ]

User Datagram Protocol (UDP)

[ *sn* ] **permit udp** { *source source-wildcard* | **host** *source* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } [ [ **precedence** *precedence* ] [ **tos** *tos* ] | [ **dscp** *dscp* ] ] [ **fragment** ] [ **range** *lower upper* ] [ **time-range** *time-range-name* ]

### 3. Extended MAC ACL

[*sn*] **permit** { **any** | **host** *source-mac-address* | *source-mac-address mask* } { **any** | **host** *destination-mac-address* | *destination-mac-address mask* } [ *ethernet-type* ] [ **cos** [ *out* ] [ **inner** *in* ] ]

### 4. Extended expert ACL

[ *sn* ] **permit** [ **protocol** | [ *ethernet-type* ] [ **cos** [ *out* ] [ **inner** *in* ] ] ] [ **VID** [ *out* ] [ **inner** *in* ] ] { *source source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ [ **precedence** *precedence* ] [ **tos** *tos* ] | [ **dscp** *dscp* ] ] [ **fragment** ] [ **range** *lower upper* ] [ **time-range** *time-range-name* ]

When you select the Ethernet-type field or cos field:

[*sn*] **permit** { *ethernet-type* | **cos** [ *out* ] [ **inner** *in* ] ] [ **VID** [ *out* ] [ **inner** *in* ] ] { *source source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ **time-range** *time-range-name* ]

When you select the protocol field:

[ *sn* ] **permit protocol** [ **VID** [ *out* ] [ **inner** *in* ] ] { *source source-wildcard* | **host** *Source* | **any** } { **host** *source-mac-address* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ [ **precedence** *precedence* ] [ **tos** *tos* ] | [ **dscp** *dscp* ] ] [ **fragment** ] [ **range** *lower upper* ] [ **time-range** *time-range-name* ]

Extended expert ACLs of some important protocols:

Internet Control Message Protocol (ICMP)

[ *sn* ] **permit icmp** [ **VID** [ *out* ] [ **inner** *in* ] ] { *source source-wildcard* | **host** *source* | **any** } { **host** *source-mac-address* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ *icmp-type* ] [ [ *icmp-type* [ *icmp-code* ] ] ] [ *icmp-message* ] ] [ [ **precedence** *precedence* ] [ **tos** *tos* ] | [ **dscp** *dscp* ] ] [ **fragment** ] [ **time-range** *time-range-name* ]

Transmission Control Protocol (TCP)

[ *sn* ] **permit tcp** [ **VID** [ *out* ] [ **inner** *in* ] ] { *source source-wildcard* | **host** *Source* | **any** } { **host** *source-mac-address* | **any** } { *destination destination-wildcard* | **host** *destination* | **any** } { **host** *destination-mac-address* | **any** } [ [ **precedence** *precedence* ] [ **tos** *tos* ] | [ **dscp** *dscp* ] ] [ **fragment** ] [ **range** *lower upper* ] [ **time-range** *time-range-name* ] [ **match-all** *tcp-flag* | **established** ]

User Datagram Protocol (UDP)

```
[ sn ] permit udp [ VID [ out ] [ inner in ] ] { source source-wildcard | host source | any } { host source-mac-address | any } { destination destination-wildcard | host destination | any } { host destination-mac-address | any } [ [precedence precedence ] [ tos tos ] | [dscp dscp] ] [ fragment ] [ range lower upper ] [ time-range time-range-name ]
```

Address Resolution Protocol (ARP)

```
[sn] permit arp {vid vlan-id} [host source-mac-address | any] [host destination-mac-address | any] {sender-ip sender-ip-wildcard | host sender-ip | any} {sender-mac sender-mac-wildcard | host sender-mac | any} {target-ip target-ip-wildcard | host target-ip | any}
```

5. Extended IPv6 ACL

```
[sn] permit protocol {source-ipv6-prefix / prefix-length | any | host source-ipv6-address} {destination-ipv6-prefix / prefix-length | any | host destination-ipv6-address} [dscp dscp] [flow-label flow-label] [fragment] [range lower upper] [time-range time-range-name]
```

Extended IPv6 ACLs of some important protocols:

Internet Control Message Protocol (ICMP)

```
[sn] permit icmp {source-ipv6-prefix / prefix-length | any source-ipv6-address | host} {destination-ipv6-prefix / prefix-length | host destination-ipv6-address | any} [icmp-type] [[icmp-type [icmp-code]] | [icmp-message]] [dscp dscp] [flow-label flow-label][fragment] [time-range time-range-name]
```

Transmission Control Protocol (TCP)

```
[ sn ] permit tcp { source-ipv6-prefix / prefix-length | host source-ipv6-address | any } { destination-ipv6-prefix / prefix-length | host destination-ipv6-address | any } [ dscp dscp ] [ flow-label flow-label ] [ fragment ] [ range lower upper ] [ time-range time-range-name ] [ match-all tcp-flag | established ]
```

User Datagram Protocol (UDP)

```
[ sn ] permit udp { source-ipv6-prefix / prefix-length | host source-ipv6-address | any } { destination-ipv6-prefix / prefix-length | host destination-ipv6-address | any } [ dscp dscp ] [ flow-label flow-label ] [ fragment ] [ range lower upper ] [ time-range time-range-name ]
```

**Parameter Description**

| Parameter            | Description                                                                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sn                   | ACL entry sequence number                                                                                                                                                                                                                              |
| permit               | If matched, access is permitted.                                                                                                                                                                                                                       |
| source               | Specify the source IP address (host address or network address).                                                                                                                                                                                       |
| source-wildcard      | It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                                                                      |
| protocol             | IP protocol number. It can be one of EIGRP, GRE, IPINIP, IGMP, NOS, OSPF, ICMP, UDP, TCP, and IP. It can also be a number representing the IP protocol between 0 and 255. The important protocols such as ICMP, TCP, and UDP are described separately. |
| destination          | Specify the destination IP address (host address or network address).                                                                                                                                                                                  |
| destination-wildcard | Wildcard of the destination IP address. It can be discontinuous, for example, 0.255.0.32.                                                                                                                                                              |
| fragment             | Packet fragment filtering                                                                                                                                                                                                                              |

|                                 |                                                                                                      |
|---------------------------------|------------------------------------------------------------------------------------------------------|
| precedence                      | Specify the packet priority.                                                                         |
| precedence                      | Packet precedence value (0 to 7)                                                                     |
| range                           | Layer4 port number range of the packet.                                                              |
| lower                           | Lower limit of the layer4 port number.                                                               |
| upper                           | Upper limit of the layer4 port number.                                                               |
| time-range                      | Time range of packet filtering                                                                       |
| time-range-name                 | Time range name of packet filtering                                                                  |
| tos                             | Specify type of service.                                                                             |
| tos                             | ToS value (0 to 15)                                                                                  |
| icmp-type                       | ICMP message type (0 to 255)                                                                         |
| icmp-code                       | ICMP message type code (0 to 255)                                                                    |
| icmp-message                    | ICMP message type name                                                                               |
| host source-mac-address         | Source physical address                                                                              |
| host destination-mac-address    | Destination physical address                                                                         |
| VID vid                         | Match the specified VID.                                                                             |
| ethernet-type                   | Ethernet type                                                                                        |
| match-all                       | Match all the bits of the TCP flag.                                                                  |
| tcp-flag                        | Match the TCP flag.                                                                                  |
| established                     | Match the RST or ACK bits, not other bits of the TCP flag.                                           |
| <i>source-ipv6-prefix</i>       | Source IPv6 network address or network type                                                          |
| <i>destination-ipv6-prefix</i>  | Destination IPv6 network address or network type                                                     |
| <i>prefix-length</i>            | Prefix mask length                                                                                   |
| <i>source-ipv6-address</i>      | Source IPv6 address                                                                                  |
| <i>destination-ipv6-address</i> | Destination IPv6 address                                                                             |
| <b>dscp</b>                     | Differential Service Code Point                                                                      |
| <i>dscp</i>                     | Code value, within the range of 0 to 63                                                              |
| flow-label                      | Flow label                                                                                           |
| <i>flow-label</i>               | Flow label value, within the range of 0 to 1048575.                                                  |
| <i>protocol</i>                 | For the IPv6, the field can be <code>ipv6   icmp   tcp   udp</code> and number in the range 0 to 255 |
| time-range                      | Time range of the packet filtering                                                                   |
| <i>time-range-name</i>          | Time range name of the packet filtering                                                              |

**Defaults** N/A

**Command mode** ACL configuration mode.

**Usage Guide** Use this command to configure the **permit** conditions for the ACL in ACL configuration mode.

**Configuration Examples** The following example shows how to create and display an Expert Extended ACL. This expert ACL permits all the TCP packets with the source IP address 192.168.4.12 and the source MAC address

001300498272.

```
Ruijie(config)#expert access-list extended exp-acl
Ruijie(config-exp-nacl)#permit tcp host 192.168.4.12 host 0013.0049.8272
any any
Ruijie(config-exp-nacl)#deny any any any any
Ruijie(config-exp-nacl)#show access-lists
expert access-list extended exp-acl
10 permit tcp host 192.168.4.12 host 0013.0049.8272 any any
20 deny any any any any
Ruijie(config-exp-nacl)#
```

This example shows how to use the extended IP ACL. The purpose is to permit the host with the IP address 192.168.4.12 to provide services through the TCP port 100 and apply the ACL to interface gigabitethernet 1/1. The configuration procedure is as below:

```
Ruijie(config)# ip access-list extended 102
Ruijie(config-ext-nacl)# permit tcp host 192.168.4.12 eq 100 any
Ruijie(config-ext-nacl)# show access-lists
ip access-list extended 102
10 permit tcp host 192.168.4.12 eq 100 any
Ruijie(config-ext-nacl)#exit
Ruijie(config)#interface gigabitethernet 1/1
Ruijie(config-if)#ip access-group 102 in
Ruijie(config-if)#
```

This example shows how to use the extended MAC ACL. The purpose is to permit the host with the MAC address 0013.0049.8272 to send Ethernet frames through the type 100 and apply the ACL to interface gigabitethernet 1/1. The configuration procedure is as below:

```
Ruijie(config)#mac access-list extended 702
Ruijie(config-mac-nacl)#permit host 0013.0049.8272 any aarp
Ruijie(config-mac-nacl)#show access-lists
mac access-list extended 702
10 permit host 0013.0049.8272 any aarp 702
Ruijie(config-mac-nacl)#exit
Ruijie(config)#interface gigabitethernet 1/1
Ruijie(config-if)#mac access-group 702 in
```

This example shows how to use the standard IP ACL. The purpose is to permit the host with the IP address 192.168.4.12 and apply the ACL to interface gigabitethernet 1/1. The configuration procedure is as below:

```
Ruijie(config)#ip access-list standard std-acl
Ruijie(config-std-nacl)#permit host 192.168.4.12
Ruijie(config-std-nacl)#show access-lists
ip access-list standard std-acl
 10 permit host 192.168.4.12
Ruijie(config-std-nacl)#exit
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if)# ip access-group std-acl in
```

This example shows how to use the extended IPV6 ACL. The purpose is to permit the host with the IP address 192.168.4.12 and apply the ACL to interface gigabitethernet 1/1. The configuration procedure is as below:

```
Ruijie(config)#ipv6 access-list extended v6-acl
Ruijie(config-ipv6-nacl)#11 permit ipv6 host ::192.168.4.12 any
Ruijie(config-ipv6-nacl)# show access-lists
ipv6 access-list extended v6-acl
11 permit ipv6 host ::192.168.4.12 any
Ruijie(config-ipv6-nacl)# exit
Ruijie(config)#interface gigabitethernet 1/1
Ruijie(config-if)#ipv6 traffic-filter v6-acl in
```

#### Related Commands

| Command             | Description                                             |
|---------------------|---------------------------------------------------------|
| show access-lists   | Displays all access lists.                              |
| ipv6 traffic-filter | Applies the extended IPv6 access list to the interface. |
| ip access-group     | Applies the IP access list to the interface.            |
| mac access-group    | Applies the extended MAC access list to the interface.  |
| ip access-list      | Defines an IP access list.                              |
| mac access-list     | Defines an extended MAC access list.                    |
| expert access-list  | Define an extended expert access list.                  |
| ipv6 access-list    | Defines an extended IPv6 access list.                   |
| deny                | Defines the <b>deny</b> access entry.                   |

**Platform** N/A

**Description**

## 1.32 redirect destination interface

Use this command to redirect the traffic matching the access list to the specified interface. Use the **no** form of this command to remove the redirection.

**redirect destination interface** *interface-name* **acl** { *id* | *name* } **in**

**no redirect destination interface** *interface-name* **acl** { *id* | *name* } **in**

#### Parameter Description

| Parameter             | Description        |
|-----------------------|--------------------|
| <i>interface-name</i> | Redirect interface |
| <i>id</i>             | Access list number |
| <i>name</i>           | Access list name   |

**Defaults** No redirection is configured.

**Command mode** Interface configuration mode

**Usage Guide** Use this command to configure access redirection, namely, to redirect the traffic matching the access list to the specified interface. You can monitor the operation of a specified access list by using this command.

**Configuration** The following example configures access redirection.

**Examples**

```
Ruijie(config)# interface gigabitEthernet 0/3
Ruijie(config-if-GigabitEthernet 0/3)# redirect destination interface
gigabitEthernet 0/2 acl1 in
```

**Related Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform Description** N/A

## 1.33 remark

Use this command to write a helpful comment (remark) for an entry in the access list. Use the **no** form of this command to remove the remark.

**[sn] remark text**

**no [sn] remark**

**Parameter Description**

| Parameter   | Description                              |
|-------------|------------------------------------------|
| <i>text</i> | Comment that describes the access entry. |
| <i>sn</i>   | The sequence number of the ACE.          |

**Defaults** The access entries have no remarks.

**Command mode** ACL configuration mode.

**Usage Guide** Use this command to write a helpful comment for an access entry. Up to 100 characters are allowed in the remark. Two access entry remarks in one access list entry are not allowed. Removing an access entry may delete the remark for it as well. If *sn* is specified, the remark is applied to the specified ACE; otherwise, the remark is applied to the

last ACE.

**Configuration** The following example writes remarks for the entry in extended IP access list 102.

**Examples**

```
Ruijie(config)# ip access-list extended 102
Ruijie(config-ext-nacl)# remark first_remark
Ruijie(config-ext-nacl)# 10 permit tcp 1.1.1.1 0.0.0.0 2.2.2.2 0.0.0.0
Ruijie(config-ext-nacl)# 10 remark second_remark
Ruijie(config-ext-nacl)# permit tcp 3.3.3.3 0.0.0.0 4.4.4.4 0.0.0.0
Ruijie(config-ext-nacl)# end
Ruijie#
```

**Related  
Commands**

| Command           | Description                |
|-------------------|----------------------------|
| show access-lists | Displays all access lists. |
| ip access-list    | Defines an IP access list. |

**Platform** N/A

**Description**

## 1.34 security access-group

Use this command to configure an interface secure channel. Use the **no** form of this command to restore to default settings.

**security access-group** { *id* | *name* }

**no security access-group**

**Parameter  
Description**

| Parameter   | Description              |
|-------------|--------------------------|
| <i>id</i>   | Access list number.      |
| <i>name</i> | Name of the access list. |

**Defaults** N/A

**Command  
mode** Interface configuration mode

**Usage Guide** If a device is configured authentications such as 802.1x or Web authentication, the user cannot access the external network before passing the authentication. You can use this command to configure a secure channel for the users on the specified interface to access the external network without authentication.

**Configuration** The following example configures a secure channel on interface GigaEthernet 1/1:

**Examples**

```
Ruijie(config)# interface GigaEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# security access-group 1
```

**Related  
Commands**

| Command       | Description                                |
|---------------|--------------------------------------------|
| show secu-acl | Displays the secure channel configuration. |

**Platform** N/A  
**Description**

## 1.35 security global access-group

Use this command to configure the global secure channel.

**security global access-group** { *id* | *name* }

**no security global access-group**

**Parameter  
Description**

| Parameter   | Description              |
|-------------|--------------------------|
| <i>id</i>   | Access list number.      |
| <i>name</i> | Name of the access list. |

**Defaults** -

**Command mode** Global configuration mode

**Usage Guide** If a device is configured authentications such as 802.1x or Web authentication, the user cannot access the external network before passing the authentication. You can use this command to configure a global secure channel for some users to access the external network without authentication.

**Configuration Examples** The following example configures a global secure channel.

```
Ruijie(config)#security global access-group 1
```

**Related  
Commands**

| Command       | Description                                 |
|---------------|---------------------------------------------|
| show secu-acl | Displays the secure channel configuration.. |

**Platform** N/A  
**Description**

## 1.36 security uplink enable

Use this command to configure an exceptional interface of the global secure channel.

**security uplink enable**

**no security uplink enable****Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The global secure channel takes effect on all interfaces by default.

**Command mode** Interface configuration mode.

**Usage Guide** The global secure channel takes effect on all interfaces by default. To disable the secure channel function on some interfaces, you can use this command to configure the interface as exceptional.

**Configuration Examples** The following example configures interface GigaEthernet 1/1 as an exceptional interface of the secure channel.

```
Ruijie(config)# interface GigaEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# security uplink enable
```

**Related  
Commands**

| Command       | Description                                |
|---------------|--------------------------------------------|
| show secu-acl | Displays the secure channel configuration. |

**Platform Description** N/A

## 1.37 show access-group

Use this command to display the access list applied to the interface.

**show access-group [ interface *interface-name* ]**

**Parameter  
Description**

| Parameter        | Description    |
|------------------|----------------|
| <i>interface</i> | Interface name |

**Defaults** -

**Command mode** Privileged EXEC mode

**Usage Guide** Use this command to display the access list configuration on the specified interface. If no interface is specified, access list configuration on all interfaces is displayed.

**Configuration** Ruijie# show access-group

**Examples**

```
ip access-list standard ipstd3
Applied On interface GigabitEthernet 0/1.
ip access-list standard ipstd4
Applied On interface GigabitEthernet 0/2.
ip access-list extended 101
Applied On interface GigabitEthernet 0/3.
ip access-list extended 102
Applied On interface GigabitEthernet 0/8.
```

**Related  
Commands**

| Command             | Description                                      |
|---------------------|--------------------------------------------------|
| ip access-group     | Applies the IP access list to the interface.     |
| mac access-group    | Applies the MAC access list to the interface.    |
| expert access-group | Applies the expert access list to the interface. |
| ipv6 traffic-filter | Applies the IPv6 access list to the interface.   |

**Platform** N/A**Description**

## 1.38 show access-lists

Use this command to display all access lists or the specified access list.

**show access-lists** [ *id* | *name* ] [ **summary** ]

**Parameter  
Description**

| Parameter   | Description                |
|-------------|----------------------------|
| <i>id</i>   | Access list number         |
| <i>name</i> | Name of the IP access list |
| summary     | Access list summary        |

**Defaults** N/A**Command  
mode** Global configuration mode**Usage Guide** Use this command to display the specified access list. If no access list number or name is specified, all the access lists are displayed.**Configuration****Examples**

```
Ruijie# show access-lists n_acl
ip access-list standard n_acl
Ruijie# show access-lists 102
ip access-list extended 102
```

```
Ruijie# show access-lists
ip access-list standard n_acl
ip access-list extended 101
permit icmp host 192.168.1.1 any log (1080 matches)
  permit tcp host 1.1.1.1 any established
  deny ip any any (80021 matches)
mac access-list extended mac_acl
expert access-list extended exp_acl
ipv6 access-list extended v6_acl
petmit ipv6 ::192.168.4.12 any (100 matches)
deny any any (9 matches)
```

**Related Commands**

| Command            | Description                             |
|--------------------|-----------------------------------------|
| ip access-list     | Defines an IP access list.              |
| mac access-list    | Defines an extended MAC access list.    |
| expert access-list | Defines an extended expert access list. |
| ipv6 access-list   | Defines an extended IPv6 access list.   |

**Platform** N/A

**Description**

### 1.39 show expert access-group

Use this command to display the expert access list applied to the interface.

**show expert access-group [ interface *interface-name* ]**

**Parameter Description**

| Parameter             | Description    |
|-----------------------|----------------|
| <i>interface-name</i> | Interface name |

**Defaults** -

**Command mode** Privileged EXEC mode

**Usage Guide** Use this command to display the expert access list configured on the interface. If no interface is specified, the expert access lists on all interfaces are displayed.

**Configuration Examples**

```
Ruijie# show expert access-group interface gigabitethernet 0/2
expert access-group ee in
Applied On interface GigabitEthernet 0/2.
```

**Related**

| Command | Description |

| Commands           |                                         |
|--------------------|-----------------------------------------|
| expert access-list | Defines an extended expert access list. |

**Platform** N/A

**Description**

## 1.40 show ip access-group

Use this command to display the standard and extended IP access lists on the interface.

**show ip access-group [ interface *interface-name* ]**

| Parameter Description | Parameter                       | Description    |
|-----------------------|---------------------------------|----------------|
|                       | <i>Interface Interface-name</i> | Interface name |

**Defaults** N/A

**Command mode** Privileged EXEC mode

**Usage Guide** Use this command to display the standard and extended IP access lists configured on the interface. If no interface is specified, the standard and extended IP access lists on all interfaces are displayed.

**Configuration Examples**

```
Ruijie# show ip access-group interface gigabitethernet 0/1
ip access-group aaa in
Applied On interface GigabitEthernet 0/1.
```

| Related Commands | Command        | Description                |
|------------------|----------------|----------------------------|
|                  | ip access-list | Defines an IP access list. |

**Platform** N/A

**Description**

## 1.41 show ipv6 traffic-filter

Use this command to display the IPv6 access list on the interface.

**show ipv6 traffic-filter [ interface *interface-name* ]**

| Parameter Description | Parameter             | Description    |
|-----------------------|-----------------------|----------------|
|                       | <i>interface-name</i> | Interface name |

**Defaults**

-

**Command mode**

Privileged EXEC mode

**Usage Guide**

Use this command to display the IPv6 access list configured on the interface. If no interface is specified, the IPv6 access lists on all interfaces are displayed.

**Configuration**

```
Ruijie# show ipv6 traffic-filter interface gigabitethernet 0/4
```

**Examples**

```
ipv6 access-group v6 in
Applied On interface GigabitEthernet 0/4.
```

**Related Commands**

| Command          | Description                  |
|------------------|------------------------------|
| ipv6 access-list | Defines an IPv6 access list. |

**Platform**

N/A

**Description**

## 1.42 show mac access-group

Use this command to display the MAC access list on the interface.

**show mac access-group [ interface *interface-name* ]**

**Parameter Description**

| Parameter             | Description    |
|-----------------------|----------------|
| <i>interface-name</i> | Interface name |

**Defaults**

N/A

**Command mode**

Privileged EXEC mode

**Usage Guide**

Use this command to display the MAC access list configured on the interface. If no interface is specified, the MAC access lists on all interfaces are displayed.

**Configuration**

```
Ruijie# show mac access-group interface gigabitethernet 0/3
```

**Examples**

```
mac access-group mm in
Applied On interface GigabitEthernet 0/3.
```

**Related Commands**

| Command         | Description                |
|-----------------|----------------------------|
| mac access-list | Defines a MAC access list. |

**Platform** N/A  
**Description**

## 1.43 show redirect interface

Use this command to display the access redirection configuration.

**show redirect [ interface *interface-name* ]**

| Parameter Description | Parameter                              | Description    |
|-----------------------|----------------------------------------|----------------|
|                       | <b>interface</b> <i>interface-name</i> | Interface name |

**Defaults** N/A

**Command mode** Privileged EXEC mode

**Usage Guide** Use this command to display the access redirection configuration on the interface. If no interface is specified, the access redirection configuration on all interfaces is displayed.

**Configuration Examples** The following example displays the access redirection configuration on interface GigabitEthernet 0/3.

```
Ruijie #show redirect interface gigabitEthernet 0/3
acl redirect configuration on interface gigabitEthernet 0/3
redirect destination interface gigabitEthernet 0/3 acl 1 in
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A  
**Description**

## 1.44 svi router-acls enable

Use this command to enable the SVI filter only for the Layer3 packets. Use the **no** form of this command to disable this function.

**svi router-acls enable**

**no svi router-acls enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|     |      |
|-----|------|
| N/A | N/A. |
|-----|------|

**Defaults** The SVI filter takes effect for both Layer2 and Layer3 packets by default.

**Command mode** Global configuration mode

**Usage Guide** Use this command to make the SVI filter take effect only for the Layer3 packets,

**Configuration** The following example enables the SVI filter only for the Layer3 packets.

**Examples** Ruijie(config)#svi router-acls enable

| Related Commands | Command | Description |

|                  | N/A     | N/A         |

**Platform Description** N/A

## 2 QoS Commands

### 2.1 class

Use this command to add reference to an existing class map. Use the **no** form of this command to remove the class from the policy map.

**class** *class-map-name*

**no class** *class-map-name*

| Parameter   | Parameter             | Description               |
|-------------|-----------------------|---------------------------|
| Description | <i>class-map-name</i> | Reference to a class map. |

**Defaults** The function is disabled by default.

**Command Mode** Policy configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example adds reference to the class map named cmap1.

```
Ruijie(config)# class-map cmap1
Ruijie(config-cmap)# match ip dscp 5
Ruijie(config-cmap)# exit

Ruijie(config)# policy-map pmap1
Ruijie(config-pmap)# class cmap1
Ruijie(config-pmap-c)# end
```

| Related Commands | Command                                                                                  | Description              |
|------------------|------------------------------------------------------------------------------------------|--------------------------|
|                  | <b>show policy-map</b> [ <i>policy-map-name</i> [ <b>class</b> <i>class-map-name</i> ] ] | Displays the policy map. |

**Platform Description** N/A

## 2.2 class map

Use this command to create a class map and enter class-map configuration mode. Use the **no** or **default** form of this command to remove a class map.

**class-map** *class-map-name*

**no class-map** *class-map-name*

**default class-map** *class-map-name*

| Parameter   | Parameter             | Description                                                           |
|-------------|-----------------------|-----------------------------------------------------------------------|
| Description | <i>class-map-name</i> | Class map name. The class map name can be a maximum of 31 characters. |

**Defaults** None

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example creates a class map named cm\_acl to match an access list named me.

```
Ruijie(config)# mac access-list extended me
Ruijie(config-ext-macl)# permit host 1111.2222.3333 any
Ruijie(config-ext-macl)# exit

Ruijie(config)# class-map cm_acl
Ruijie(config-cmap)# match access-group me
Ruijie(config-cmap)# exit
```

The following example creates a class map named cm\_dscp to match DHCP 8, 16 and 24.

```
Ruijie(config)# class-map cm_dscp
Ruijie(config-cmap)# match ip dscp 8 16 24
Ruijie(config-cmap)# exit
```

| Related Commands | Command                                         | Description             |
|------------------|-------------------------------------------------|-------------------------|
|                  | <b>show class-map</b> [ <i>class-map-name</i> ] | Displays the class map. |

**Platform Description** N/A

## 2.3 drr-queue bandwidth

Use this command to set the DRR queue weight ratio. Use the **no** or **default** form of this command to restore the default setting.

**drr-queue bandwidth** *weight1...weight8*

**no drr-queue bandwidth**

**default drr-queue bandwidth**

| Parameter   | Parameter                | Description                                                                                                                                                                                                                                             |
|-------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>weight1...weight8</i> | 8 queue weights. The default queue weight ratio is 1:1:1:1:1:1:1:1. For the products supporting the SP scheduling policy, the weight range is from 0 to 15. For the products not supporting the SP scheduling policy, the weight range is from 1 to 15. |

**Defaults** The default queue weight ratio is 1:1:1:1:1:1:1:1.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example configures the DRR queue weight ratio to 1:1:1:2:2:4:6:8.

### Examples

```
Ruijie(config)# drr-queue bandwidth 1:1:1:2:2:4:6:8
```

| Related Commands | Command                     | Description                           |
|------------------|-----------------------------|---------------------------------------|
|                  | <b>show mls qos queuing</b> | Displays information about the queue. |

**Platform Description** N/A

## 2.4 match

Use this command to define a match criteria in class map configuration mode. Use the **no** form of this command to remove the match criteria.

**match** { **access-group** *access\_list* | **ip** { **dscp** *dscp-vlaue-list* | **precedence** *pre-vlaue-list* } }

**no match** { **access-group** *access\_list* | **ip** { **dscp** *dscp-vlaue-list* | **precedence** *pre-vlaue-list* } }

| Parameter   | Parameter                              | Description                                                                                               |
|-------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Description | <b>access-group</b> <i>access_list</i> | Identifies a numbered or named access list as the match criteria.                                         |
|             | <b>ip dscp</b> <i>dscp-vlaue-list</i>  | Identifies DSCP values as the match criteria. Multiple DSCP can be configured. The range is from 0 to 63. |

**Defaults** None

**Command Mode** Class map configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example creates a class map named cmap1 to match DSCP 20, 22, 24 and 30.

```
Ruijie(config)# class-map cmap1
Ruijie(config-cmap)# match ip dscp 20 22 24 30
```

|-------------------------------------------------|-------------------------|
| <b>show class-map</b> [ <i>class-map-name</i> ] | Displays the class map. |

**Platform** N/A

**Description**

## 2.5 mls qos cos

Use this command to configure the CoS value of an interface. Use the **no** form of this command to restore the default setting.

**mls qos cos** *default-cos*

**no mls qos cos**

| Parameter          | Parameter          | Description                                           |
|--------------------|--------------------|-------------------------------------------------------|
| <b>Description</b> | <i>default-cos</i> | CoS value of the interface. The range is from 0 to 7. |

**Defaults** The default CoS value is 0.

**Command Mode** Interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example configures the default CoS value to 7.

```
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if)# mls qos cos 7
```

**Related Commands**

| Command                                           | Description                                      |
|---------------------------------------------------|--------------------------------------------------|
| <b>show mls qos interface</b> <i>interface-id</i> | Displays information of the specified interface. |

**Platform** N/A  
**Description**

## 2.6 mls qos map cos-dscp

Use this command to map the CoS value to the DSCP value. Use the **no** or **default** form of this command to restore the default CoS-DSCP mapping.

**mls qos map cos-dscp** *dscp1...dscp8*  
**no mls qos map cos-dscp**  
**default mls qos map cos-dscp**

| Parameter          | Parameter            | Description                                          |
|--------------------|----------------------|------------------------------------------------------|
| <b>Description</b> | <i>dscp1...dscp8</i> | Specifies the DSCP value. The range is from 0 to 63. |

**Defaults** By default, the CoS 0, 1, 2, 3, 4, 5, 6, 7 is mapped to the DSCP 0, 8, 16, 24, 32, 40, 48, 56 respectively.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples**

```
Ruijie(config)# mls qos map cos-dscp 8 10 16 18 24 26 32 34
```

| Related Commands | Command                           | Description                    |
|------------------|-----------------------------------|--------------------------------|
|                  | <b>show mls qos maps cos-dscp</b> | Displays the CoS-DSCP mapping. |

**Platform** N/A  
**Description**

## 2.7 mls qos map dscp-cos

Use this command to map the DSCP value to the CoS value. Use the **no** or **default** form of this command to restore the default DSCP-CoS mapping.

**mls qos map dscp-cos** *dscp-list to cos*  
**no mls qos map dscp-cos**  
**default mls qos map dscp-cos**

| Parameter          | Parameter        | Description                           |
|--------------------|------------------|---------------------------------------|
| <b>Description</b> | <i>dscp-list</i> | DSCP list. The range is from 0 to 63. |
|                    | <i>cos</i>       | CoS value. The range is from 0 to 7.  |

**Defaults** The default DSCP-CoS mapping is listed below:

|             |              |               |               |               |               |               |               |
|-------------|--------------|---------------|---------------|---------------|---------------|---------------|---------------|
| DSCP<br>0-7 | DSCP<br>8-15 | DSCP<br>16-23 | DSCP<br>24-31 | DSCP<br>32-39 | DSCP<br>40-47 | DSCP<br>48-55 | DSCP<br>56-63 |
| CoS 0       | CoS 1        | CoS 2         | CoS 3         | CoS 4         | CoS 5         | CoS 6         | CoS 7         |

**Command** Global configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration Examples** Ruijie(config)# mls qos map dscp-cos 8 10 16 18 to 0

| Related         | Command                       | Description                    |
|-----------------|-------------------------------|--------------------------------|
| <b>Commands</b> | show mls qos maps<br>dscp-cos | Displays the DSCP-CoS mapping. |

**Platform** N/A

**Description**

## 2.8 mls qos map ip-precedence-dscp

Use this command to map the IP precedence to the DSCP value. Use the **no** or **default** form of this command to restore the default IP-precedence to DSCP mapping.

**mls qos map ip-precedence-dscp** *dscp1 ... dscp8*

**no mls qos map ip-precedence-dscp**

**default mls qos map ip-precedence-dscp**

| Parameter          | Parameter            | Description                           |
|--------------------|----------------------|---------------------------------------|
| <b>Description</b> | <i>dscp1...dscp8</i> | DSCP list. The range is from 0 to 63. |

**Defaults** By default, the IP precedence 0, 1, 2, 3, 4, 5, 6, 7 is mapped to the DSCP 0, 8, 16, 24, 32, 40, 48, 56 respectively.

**Command** Global configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration Examples** Ruijie(config)# mls qo map ip-prec -dscp 8 10 16 18 24 26 32 34

| <b>Related Commands</b> | <b>Command</b>                       | <b>Description</b>                          |
|-------------------------|--------------------------------------|---------------------------------------------|
|                         | <b>show mls qos maps ip-pre-dscp</b> | Displays the IP-precedence to DSCP mapping. |

**Platform** N/A  
**Description**

## 2.9 mls qos scheduler

Use this command to configure the output queue scheduling. Use the **no** or **default** form of this command to restore the default scheduler.

**mls qos scheduler [ sp | rr | wrr | drr ]**  
**no mls qos scheduler**

| <b>Parameter Description</b> | <b>Parameter</b> | <b>Description</b>                                          |
|------------------------------|------------------|-------------------------------------------------------------|
|                              | <b>sp</b>        | Specifies the absolute priority scheduling.                 |
|                              | <b>rr</b>        | Specifies the round-robin scheduling.                       |
|                              | <b>wrr</b>       | Specifies the frame count weighted round-robin scheduling.  |
|                              | <b>drr</b>       | Specifies the frame length weighted round-robin scheduling. |

**Defaults** The default queue scheduling is **wrr** globally, no queue scheduling is configured on the interface.

**Command Mode** Global configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example specifies the sp scheduling.

```
Ruijie(config)# mls qos scheduler sp
```

| <b>Related Commands</b> | <b>Command</b>                | <b>Description</b>                    |
|-------------------------|-------------------------------|---------------------------------------|
|                         | <b>show mls qos scheduler</b> | Displays the output queue scheduling. |

**Platform** N/A  
**Description**

## 2.10 mls qos trust

Use this command to configure the trust mode on an interface. Use the **no** or **default** form of this command to restore the default setting.

**mls qos trust { cos | dscp | ip-precedence }**  
**no mls qos trust**  
**default mls qos trust**

| Parameter   | Parameter            | Description                      |
|-------------|----------------------|----------------------------------|
| Description | <b>cos</b>           | Specifies the CoS trust mode.    |
|             | <b>dscp</b>          | Specifies the DSCP trust mode.   |
|             | <b>ip-precedence</b> | Specifies the IP-PRE trust mode. |

**Defaults** No trust mode is configured by default.

**Command** Interface configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example configures the CoS trust mode.

**Examples**

```
Ruijie(config)# interface gigabitethernet 1/1
Ruijie(config-if)# mls qos trust cos
```

| Related  | Command                                           | Description                                     |
|----------|---------------------------------------------------|-------------------------------------------------|
| Commands | <b>show mls qos interface</b> <i>interface-id</i> | Displays the specified interface configuration. |

**Platform** N/A

**Description**

## 2.11 police

Use this command to configure traffic policing for a class map in a policy map. Use the **no** form of this command to remove traffic policing for the class map.

**police** *rate-bps burst-byte* [ **exceed-action** { **drop** | **dscp** *new-dscp* | **cos** *new-cos* [ **none-tos** ] } ]

**no police**

| Parameter   | Parameter                   | Description                                                                                                                                  |
|-------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>rate-bps</i>             | Bandwidth limit value per second (The unit is KBits). This value depends on the specific product.                                            |
|             | <i>burst-byte</i>           | Burst traffic limit value (The unit is KBytes). This value depends on the specific product.                                                  |
|             | <b>drop</b>                 | Drops the packet. This is available only when the packet exceeds the bandwidth limit.                                                        |
|             | <b>dscp</b> <i>new-dscp</i> | Modifies the DSCP value of the packet. This is available only when the packet exceeds bandwidth limit. The DSCP value range is from 0 to 63. |
|             | <b>cos</b> <i>new-cos</i>   | Modifies the CoS value of the packet. This is available only when the packet exceeds bandwidth limit. The CoS value range is from 0 to 7.    |

|                 |                              |
|-----------------|------------------------------|
| <b>none-tos</b> | Modifies the CoS value only. |
|-----------------|------------------------------|

**Defaults** No traffic policing is configured for the class map by default.

**Command Mode** Policy map class configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example configures traffic policing which modifies the DSCP value of the packet to 16 for class map "cm-acl" in policy map "pmap1".

```
Ruijie(config)# policy-map pmap1
Ruijie(config-pmap)# class cm-acl

Ruijie(config-pmap-c)# police 102400 4096 exceed-action dscp 16
```

| Related Commands | Command                                                                                  | Description                            |
|------------------|------------------------------------------------------------------------------------------|----------------------------------------|
|                  | <b>show policy-map</b> [ <i>policy-map-name</i> [ <b>class</b> <i>class-map-name</i> ] ] | Displays the policy map configuration. |

**Platform Description** N/A

## 2.12 policy map

Use the following command to create a policy map and enter policy map configuration mode. Use the **no** or **default** form of this command to remove the specified policy map.

**policy-map** *policy-map-name*

**no policy-map** *policy-map-name*

**default policy-map** *policy-map-name*

| Parameter Description | Parameter              | Description                                                             |
|-----------------------|------------------------|-------------------------------------------------------------------------|
|                       | <i>policy-map-name</i> | Policy map name. The policy map name can be a maximum of 31 characters. |

**Defaults** No policy map is configured by default.

**Command Mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example creates policy map “po”, and then adds a reference to class map “cmap1”.

**Examples** Sets the rate limit value to 10 Mbps, the burst traffic limit value to 256 Kbps, and discard packets which exceed the limit.

```
Ruijie(config)# policy-map po
Ruijie(config-pmap)# class cmap1
Ruijie(config-pmap-c)# police 10240 256 exceed-action drop
```

| Related Commands | Command                                                                                  | Description                            |
|------------------|------------------------------------------------------------------------------------------|----------------------------------------|
|                  | <b>show policy-map</b> [ <i>policy-map-name</i> [ <b>class</b> <i>class-map-name</i> ] ] | Displays the policy map configuration. |

**Platform** N/A

**Description**

## 2.13 priority-queue

Use this command to configure the output queue scheduling policy to SP. Use the **no** or **default** form of this command to restore the default queue scheduling policy.

**priority-queue**

**no priority-queue**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** The default output queue scheduling policy is WRR.

**Command** Global configuration mode.

**Mode**

**Usage Guide** This command shares the same configuration with the **mls qos scheduler sp**. The **show run** command displays this configuration in the **mls qos scheduler sp** item instead of **priority-queue**.

**Configuration** The following example configures the output queue scheduling policy to SP.

**Examples**

```
Ruijie(config)# priority-queue
```

| Related Commands | Command                       | Description                                  |
|------------------|-------------------------------|----------------------------------------------|
|                  | <b>show mls qos scheduler</b> | Displays the output queue scheduling policy. |

**Platform** N/A

**Description**

## 2.14 priority-queue cos-map

Use this command to configure the mapping between the CoS value and the queue ID. Use the **no** or **default** form of this command to restore the default CoS mapping to the queue.

**priority-queue cos-map** *qid* *cos0* [*cos1* [*cos2* [*cos3* [*cos4* [*cos5* [*cos6* [*cos7*]]]]]]]

**no priority-queue cos-map**

**default priority-queue cos-map**

| Parameter   | Parameter            | Description                          |
|-------------|----------------------|--------------------------------------|
| Description | <i>qid</i>           | Queue ID. The range is from 1 to 8.  |
|             | <i>cos0 ... cos7</i> | CoS value. The range is from 0 to 7. |

**Defaults** The default mapping between the CoS value and the queue ID is listed below:

| Queue 1 | Queue 2 | Queue 3 | Queue 4 | Queue 5 | Queue 6 | Queue 7 | Queue 8 |
|---------|---------|---------|---------|---------|---------|---------|---------|
| CoS 0   | CoS 1   | CoS 2   | CoS 3   | CoS 4   | CoS 5   | CoS 6   | CoS 7   |

**Command** Global configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration** The following example maps the CoS 3, 5 to the output queue 1.

**Examples**

```
Ruijie(config)#priority-queue cos-map 1 3 5
```

| Related  | Command                     | Description                 |
|----------|-----------------------------|-----------------------------|
| Commands | <b>show mls qos queuing</b> | Displays the output queues. |

**Platform** N/A

**Description**

## 2.15 qos mc-queue cos-map

This command is used to configure the mapping between CoS values of multicast queues.

**qos mc-queue cos-map** *cos0-qid* *cos1-qid* *cos2-qid* *cos3-qid* *cos4-qid* *cos5-qid* *cos6-qid* *cos7-qid*

**no qos mc-queue cos-map**

| Parameter   | Parameter       | Description                                                                                                       |
|-------------|-----------------|-------------------------------------------------------------------------------------------------------------------|
| Description | <i>cosN-qid</i> | Queue ID mapped by the packet whose CoS is N. The value of N ranges from 0 to 7, and queue ID ranges from 1 to 3. |

**Defaults** The default value is different from products.

**Command** Global configuration mode

**Mode**

**Usage Guide** In the case of default configuration, the relevant trust mode must be enabled. For example, packets can enter the default mapped queue only when CoS is trusted.

**Configuration Examples**

The following example sets the CoS 0, 1, 2, 3, 4, 5, 6, 7 to be mapped to the multicast queues 1 1 1 2 2 2 2 3 respectively.

```
Ruijie(config)# qos mc-queue cos-map 1 1 1 2 2 2 2 3
```

**Related Commands**

| Command                          | Description                                     |
|----------------------------------|-------------------------------------------------|
| <b>show qos mc-queue cos-map</b> | This command is used to view the queue mapping. |

**Platform** N/A  
**Description**

## 2.16 qos queue

Use this command to configure a minimum or maximum of the interface bandwidth to a queue. Use the **no** or **default** form of this command to remove the minimum or maximum of the interface bandwidth.

**qos queue** *queue-id* **bandwidth** { **minimum** | **maximum** } *bandwidth*

**no qos queue** *queue-id* **bandwidth** { **minimum** | **maximum** }

**default qos queue** *queue-id* **bandwidth** { **minimum** | **maximum** }

**Parameter Description**

| Parameter                                                                   | Description                                                                                                                                                 |
|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>queue</b>                                                                | Configure the minimum or maximum of the interface bandwidth to the queue on the device supporting both unicast and multicast queue bandwidth configuration. |
| <i>queue-id</i>                                                             | Queue ID. The range is from 1 to 8.                                                                                                                         |
| <b>bandwidth</b><br>{ <b>minimum</b>   <b>maximum</b> }<br><i>bandwidth</i> | Bandwidth value. The value range depends on the specific product.                                                                                           |

**Defaults** No minimum or maximum of interface bandwidth to a queue is configured by default.

**Command Mode** Interface configuration mode

**Usage Guide** Support global configuration mode and interface configuration mode. Function that these two modes support is different.

**Configuration Examples** The following example configures the minimum interface bandwidth of queue 1 to 5 Mbps and the maximum to 10 Mbps; the minimum interface bandwidth of queue 2 to 1 Mbps and the maximum to 5

Mbps;

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# qos queue 1 bandwidth maximum 10240
Ruijie(config-if-GigabitEthernet 0/1)# qos queue 1 bandwidth minimum 5120
Ruijie(config-if-GigabitEthernet 0/1)# qos queue 2 bandwidth minimum 2048
```

| Related Commands | Command                                               | Description                                    |
|------------------|-------------------------------------------------------|------------------------------------------------|
|                  | <b>show qos bandwidth [ interfaces interface-id ]</b> | Displays the interface bandwidth of the queue. |

**Platform** N/A  
**Description**

## 2.17 queueing wred

Use this command to enable the WRED (Weighted Random Early Detection) function. Use the **no** or **default** form of this command to disable the WRED function.

**queueing wred**

**no queueing wred**

**default queueing wred**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** WRED is disabled by default.

**Command Mode** Global configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables WRED.

```
Ruijie(config)# queueing wred
```

| Related Commands | Command | Description |
|------------------|---------|-------------|

**Platform** N/A  
**Description**

## 2.18 rate-limit

Use this command to configure rate limiting on the interface. Use the **no** or **default** form of this command to remove rate limiting from the interface.

**rate-limit** { **input** | **output** } *bps burst-size*

**no rate-limit** { **input** | **output** }

**default rate-limit** { **input** | **output** }

| Parameter   | Parameter         | Description                                                                                       |
|-------------|-------------------|---------------------------------------------------------------------------------------------------|
| Description | <b>input</b>      | Configures input rate limiting.                                                                   |
|             | <b>output</b>     | Configures output rate limiting.                                                                  |
|             | <i>bps</i>        | Bandwidth limit value per second (The unit is KBits). This value depends on the specific product. |
|             | <i>burst-size</i> | Burst traffic limit value (The unit is KBytes). This value depends on the specific product.       |

**Defaults** Rate limiting is not configured by default.

**Command** Interface configuration mode.

**Mode**

**Usage Guide** N/A

**Configuration Examples** The following example configures the rate limit value to 10 Mbps, and the burst traffic limit value to 256 Kbps.

```
Ruijie(config)# interface gigabitethernet 1/3
Ruijie(config-if-GigabitEthernet 1/3)# rate-limit input 10240 256
```

| Related Commands | Command                                                                 | Description                                                |
|------------------|-------------------------------------------------------------------------|------------------------------------------------------------|
|                  | <b>show mls qos rate-limit</b> [ <b>interface</b> <i>interface-id</i> ] | Displays the rate limiting configuration of the interface. |

**Platform** N/A

**Description**

## 2.19 service-policy

Use this command to apply the policy map to the interface, the virtual group or globally. Use the **no** or **default** form of this command to remove the policy map.

**service-policy** { **input** | **output** } *policy-map-name*

**no service-policy** { **input** | **output** } *policy-map-name*

**default service-policy** { **input** | **output** } *policy-map-name*

| Parameter   | Parameter              | Description                                     |
|-------------|------------------------|-------------------------------------------------|
| Description | <i>policy-map-name</i> | Policy map name                                 |
|             | <b>input</b>           | Applies the policy map to the input direction.  |
|             | <b>output</b>          | Applies the policy map to the output direction. |

**Defaults** No policy map is configured on the interface or virtual group by default.

**Command Mode** Interface configuration mode, and virtual group configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example applies policy map “po” to the input direction of interface GigabitEthernet 1/3.

```
Ruijie(config)# interface gigabitethernet 1/3
Ruijie(config-if-GigabitEthernet 1/3)# service-policy input po
```

The following example applies policy map “po” to the output direction of virtual group 3.

```
Ruijie(config)# virtual-group 3
Ruijie(config-VirtualGroup)# service-policy output po
```

| Related Commands | Command                                    | Description                                                 |
|------------------|--------------------------------------------|-------------------------------------------------------------|
|                  | <b>show mls qos interface policers</b>     | Displays the policy map configuration on the interface.     |
|                  | <b>show mls qos virtual-group policers</b> | Displays the policy map configuration on the virtual group. |

**Platform Description** N/A

## 2.20 set

Use this command to configure the CoS, DSCP or VID value for the traffic. Use the **no** form of this command to remove the CoS, DSCP or VID value from the traffic.

```
set { ip dscp new-dscp | cos new-cos | [ none-tos ] vid new-vid }
no set { ip dscp | cos | vid }
```

| Parameter   | Parameter                      | Description                                                            |
|-------------|--------------------------------|------------------------------------------------------------------------|
| Description | <b>ip dscp</b> <i>new-dscp</i> | Configures the DSCP value for the traffic. The range is from 0 to 63.  |
|             | <b>cos</b> <i>new-cos</i>      | Configures the CoS value for the traffic. The range is from 0 to 7.    |
|             | <b>none-tos</b>                | Configures the CoS value only.                                         |
|             | <b>vid</b> <i>new-vid</i>      | Configures the VID value for the traffic. The range is from 1 to 4094. |

**Defaults** No CoS, DSCP or VID value is configured for the traffic in policy map class mode.

**Command Mode** Policy map class configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example creates policy map “pmap1”, and adds a reference to class map “cmap1”.

```
Ruijie(config)# policy-map pmap1
Ruijie(config-pmap)# class cmap1
```

The following example modifies the CoS value of the traffic to 3.

```
Ruijie(config-pmap-c)# set cos 3
```

| Related Commands | Command                                                                                               | Description                                             |

|                  | <b>show</b><br><b>policy-map</b> [ <i>policy-map-name</i><br>[ <b>class</b> <i>class-map-name</i> ] ] | Displays the policy map configuration on the interface. |

**Platform** N/A

**Description**

## 2.21 show class-map

Use this command to display the class map.

**show class-map** [ *class-map-name* ]

| Parameter          | Parameter             | Description     |
|--------------------|-----------------------|-----------------|
| <b>Description</b> | <i>class-map-name</i> | Class map name. |

**Defaults** None

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays all class maps.

```
Ruijie# show class-map
```

```
Class Map cmap1
  Match ip dscp 20 40
Class Map cmap2
  Match access-group 110
```

The fields in the output of this command are described in the following table.

| Field     | Description                   |
|-----------|-------------------------------|
| Class Map | Indicates the class map name. |
| Match     | Indicates the matched rule.   |

| Related Commands | Command | Description |

**Description**

## 2.22 show mls qos interface

Use this command to display the QoS configuration of the interface.

**show mls qos interface** [ *interface-id* ] [ **policers** ]

| Parameter          | Parameter           | Description                                                |
|--------------------|---------------------|------------------------------------------------------------|
| <b>Description</b> | <i>interface-id</i> | Interface name                                             |
|                    | <b>policers</b>     | Displays the traffic policing configured on the interface. |

**Defaults** None

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the QoS configuration of interface GigabitEthernet 1/3.

```
Ruijie# show mls qos interface gigabitethernet 1/3
Interface: GigabitEthernet 1/3
Ratelimit input: 10240 256
Ratelimit output: 51200 4096
Attached input policy-map: pmap1
Attached output policy-map:
Default trust: dscp
```

```
Default cos: 3
```

The fields in the output of this command are described in the following table.

| Field                      | Description                                |
|----------------------------|--------------------------------------------|
| Interface                  | Indicates the interface name.              |
| Ratelimit input            | Indicates the input rate limit value .     |
| Ratelimit output           | Indicates the output rate limit value .    |
| Attached input policy-map  | Indicates the input policy map .           |
| Attached output policy-map | Indicates the output policy map.           |
| Default trust              | Indicates the trust mode of the interface. |
| Default cos                | Indicates the default CoS value.           |

The following example displays the QoS configuration of all interfaces.

```
Ruijie# show mls qos interface policers
Interface: GigabitEthernet 0/1
Attached input policy-map: pmap1
Attached output policy-map: pmap1
Interface: GigabitEthernet 0/2
Attached input policy-map: p1
```

## 2.23 show mls qos maps

Use this command to display DSCP-CoS mapping, CoS-DSCP mapping and IP-PRE-DSCP mapping.

**show mls qos maps [ cos-dscp | dscp-cos | ip-prec-dscp ]**

| Parameter Description | Parameter           | Description                        |
|-----------------------|---------------------|------------------------------------|
|                       | <b>cos-dscp</b>     | Displays the CoS-DSCP mapping.     |
|                       | <b>dscp-cos</b>     | Displays the DSCP-CoS mapping.     |
|                       | <b>ip-prec-dscp</b> | Displays the IP-PRE-DSCP mapping.. |

**Defaults** None

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration** The following example displays the CoS-DSCP mapping.

**Examples**

```
Ruijie# show mls qos maps cos-dscp
cos dscp
---- ----
0 0
1 8
2 16
3 24
4 32
5 40
6 48
7 56
```

The fields in the output of this command are described in the following table.

| Field | Description                       |
|-------|-----------------------------------|
| cos   | Indicates the CoS value.          |
| dscp  | Indicates the DSCP value mapped . |

The following example displays the DSCP- CoS mapping.

```
Ruijie# show mls qos maps dscp-cos
dscp cos      dscp cos      dscp cos      dscp cos
---- ----      ---- ----      ---- ----      ---- ----
0 0           1 0           2 0           3 0
4 0           5 0           6 0           7 0
8 1           9 1           10 1          11 1
12 1          13 1          14 1          15 1
16 2          17 2          18 2          19 2
20 2          21 2          22 2          23 2
24 3          25 3          26 3          27 3
28 3          29 3          30 3          31 3
32 4          33 4          34 4          35 4
36 4          37 4          38 4          39 4
40 5          41 5          42 5          43 5
```

|    |   |    |   |    |   |    |   |
|----|---|----|---|----|---|----|---|
| 44 | 5 | 45 | 5 | 46 | 5 | 47 | 5 |
| 48 | 6 | 49 | 6 | 50 | 6 | 51 | 6 |
| 52 | 6 | 53 | 6 | 54 | 6 | 55 | 6 |
| 56 | 7 | 57 | 7 | 58 | 7 | 59 | 7 |
| 60 | 7 | 61 | 7 | 62 | 7 | 63 | 7 |

The fields in the output of this command are described in the following table.

| Field | Description                      |
|-------|----------------------------------|
| dscp  | Indicates the DSCP value.        |
| cos   | Indicates the CoS value mapped . |

The following example displays the IP-PRE-DSCP mapping.

```
Ruijie# show mls qos maps ip-prec-dscp
ip-precedence dscp
-----
0 0
1 8
2 16
3 24
4 32
5 40
6 48
7 56
```

The fields in the output of this command are described in the following table.

| Field         | Description                       |
|---------------|-----------------------------------|
| ip-precedence | Indicates the IP-PRE value.       |
| dscp          | Indicates the DSCP value mapped . |

## 2.24 show mls qos queueing

Use this command to display the QoS queueing configuration.

**show mls qos queueing [ interface *interface-id* ]**

| Parameter   | Parameter                     | Description      |
|-------------|-------------------------------|------------------|
| Description | interface <i>interface-id</i> | ID of interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the QoS queuing configuration.

```
Ruijie# show mls qos queueing

Cos-queue map:

cos qid
--- ---
0 1
1 2
2 3
3 4
4 5
5 6
6 7
7 8

wrr bandwidth weights:

qid weights
--- -----
1 1
2 2
3 3
4 4
5 5
6 6
7 7
8 8
```

```

drp bandwidth weights:
qid weights
---
1 3
2 3
3 3
4 3
5 3
6 3
7 3
8 3

wfq bandwidth weights:
qid weights
---
1 3
2 4
3 5
4 6
5 7
6 8
7 9
8 10

Interface: GigabitEthernet 0/1
Wrr queue bandwidth: 1 1 1 1 2 2 2 2
Drr queue bandwidth: 1 1 2 2 2 2 4 4
Wfq queue bandwidth: 1 1 2 2 4 4 4 4
    
```

The fields in the output of this command are described in the following table.

| Field                 | Description                                                   |
|-----------------------|---------------------------------------------------------------|
| Cos-queue map         | Indicates the mapping between the CoS value and the queue ID. |
| wrr bandwidth weights | Indicates the WRR queue weight.                               |
| drr bandwidth weights | Indicates the DRR queue weight.                               |
| wfq bandwidth weights | Indicates the WFQ queue weight.                               |
| cos                   | Indicates the CoS value.                                      |

|                       |                                 |
|-----------------------|---------------------------------|
| qid                   | Indicates the queue ID.         |
| Weights               | Indicates the weight value      |
| Interface             | Interface name                  |
| wrr bandwidth weights | Indicates the WRR queue weight. |
| drr bandwidth weights | Indicates the DRR queue weight. |
| wfq bandwidth weights | Indicates the WFQ queue weight. |

```
Ruijie# show mls qos queueing interface gigabitEthernet 0/1
Interface: GigabitEthernet 0/1

Wrr queue bandwidth: 1 1 1 1 2 2 2 2
Drr queue bandwidth: 1 1 2 2 2 2 4 4
Wfq queue bandwidth: 1 1 2 2 4 4 4 4
```

|                       |                                 |

## 2.25 show mls qos rate-limit

Use this command to display the rate limiting configuration of the interface.

**show mls qos rate-limit** [ **interface** *interface-id* ]

| Parameter   | Parameter           | Description    |
|-------------|---------------------|----------------|
| Description | <i>interface-id</i> | Interface name |

**Defaults** N/A

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the rate limiting configuration of all interfaces.

```
Ruijie# show mls qos rate-limit
Interface: GigabitEthernet 0/1

rate limit input Kbps = 10240 burst = 256
```

```
Interface: GigabitEthernet 0/3
rate limit output Kbps = 102400 burst = 4096
```

The fields in the output of this command are described in the following table.

| Field                                | Description                                                                      |
|--------------------------------------|----------------------------------------------------------------------------------|
| Interface                            | Indicates the interface name.                                                    |
| rate limit input Kbps = x burst = y  | Indicates the input rate limit value, and the input burst traffic limit value.   |
| rate limit output Kbps = x burst = y | Indicates the output rate limit value, and the output burst traffic limit value. |

## 2.26 show mls qos scheduler

Use this command to display the queue scheduling policy.

**show mls qos scheduler** [ **interface** *interface-id* ]

| Parameter          | Parameter                            | Description    |
|--------------------|--------------------------------------|----------------|
| <b>Description</b> | <b>interface</b> <i>interface-id</i> | Interface name |

**Defaults** None

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the queue scheduling policy.

```
Ruijie# show mls qos scheduler
Global Multi-Layer Switching scheduling
Weighted Round Robin
Interface GigabitEthernet 0/1 Multi-Layer Switching scheduling:
Deficit Round Robin
```

The fields in the output of this command are described in the following table.

| Field                | Description                                   |
|----------------------|-----------------------------------------------|
| Weighted Round Robin | Indicates that the queue scheduling policy is |

|                     |                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | <p>WRR.</p> <p>The other queue scheduling policies are listed as follows:</p> <p>SP: Strict Priority</p> <p>RR: Round Robin</p> <p>DRR: Deficit Round Robin</p> <p>WFQ: Weighted Fair Queue</p> |
| Interface           | Interface name                                                                                                                                                                                  |
| Deficit Round Robin | The queue scheduling is DRR                                                                                                                                                                     |

## 2.27 show mls qos virtual-group

Use this command to display the policy map configuration on the virtual group.

**show mls qos virtual-group** [ *virtual-group-number* | **policers** ]

| Parameter Description | Parameter                   | Description                                                  |
|-----------------------|-----------------------------|--------------------------------------------------------------|
|                       | <i>virtual-group-number</i> | Virtual group number. The range is from 1 to 128.            |
|                       | <b>policers</b>             | Displays the policy map configuration on all virtual groups. |

**Defaults** None

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the policy map configuration on all virtual groups.

```
Ruijie# show mls qos virtual-group policers
Virtual-group: 1
Attached input policy-map: pmap1
Virtual-group: 20
Attached output policy-map: pmap2
```

The fields in the output of this command are described in the following table.

| Field | Description |
|-------|-------------|
|-------|-------------|

|                            |                                                               |
|----------------------------|---------------------------------------------------------------|
| Virtual-group              | Indicates the virtual group number.                           |
| Attached input policy-map  | Indicates the policy map applied on the input virtual group.  |
| Attached output policy-map | Indicates the policy map applied on the output virtual group. |

**Description**

## 2.28 show policy-map

Use this command to display policy maps.

**show policy-map** [ *policy-map-name* [ **class** *class-map-name* ] ]

| Parameter          | Parameter              | Description     |
|--------------------|------------------------|-----------------|
| <b>Description</b> | <i>policy-map-name</i> | Policy map name |
|                    | <i>class-map-name</i>  | Class map name  |

**Defaults** None

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays configuration of policy map "pmap1".

```
Ruijie# show policy-map pmap1

Policy Map pmap1
  Class cmap1
    set ip dscp 16
  Class cmap2
    police 10240 256 exceed-action dscp 8
  Class cmap3
    police 512000 4096 exceed-action drop
```

The fields in the output of this command are described in the following table.

| Field      | Description                                                                             |
|------------|-----------------------------------------------------------------------------------------|
| Policy Map | Indicates the policy map name.                                                          |
| Class      | Indicates the class map name.                                                           |
| set        | Indicates that the DSCP value is modified in this example.                              |
| police     | Indicates bandwidth limit configuration and the action policy for the violated packets. |

The following example displays the action policy for the traffic of class map “cmap1” in policy map “pmap1”.

```
Ruijie#show policy-map pmap1 class cmap1
Class cmap1
set ip dscp 16
```

## 2.29 show qos bandwidth

Use this command to display the bandwidth configuration.

**show qos bandwidth** [ **interfaces** *interface-id* ]

| Parameter Description | Parameter           | Description    |
|-----------------------|---------------------|----------------|
|                       | <i>interface-id</i> | Interface name |

**Defaults** None

**Command Mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the bandwidth configuration of interface GigabitEthernet 0/1. (Taking the device supporting the bandwidth configuration of the unicast queue or the multicast queue for example. )

```
Ruijie# show qos bandwidth interface gigabitEthernet 0/1
```

```

Interface: GigabitEthernet 0/1
-----
uc-queue-id | minimum-bandwidth | maximum-bandwidth
-----
          1           5120           10240
          2             0             0
          3             0             0
          4             0             0
          5             0             0
          6             0             0
          7             0             0
          8             0             0
-----
Total ucast-queue minimum-bandwidth:           5120
Total ucast-queue maximum-bandwidth:          10240

Interface: GigabitEthernet 0/1
-----
mc-queue-id | minimum-bandwidth | maximum-bandwidth
-----
          1           1024           5120
          2             0             0
          3             0             0
          4             0            2048
-----
Total mcast-queue minimum-bandwidth:           1024
Total mcast-queue maximum-bandwidth:          5120
    
```

The fields in the output of this command are described in the following table.

| Field             | Description                                    |
|-------------------|------------------------------------------------|
| Interface         | Indicates the interface name.                  |
| queue-id          | Indicates the queue ID.                        |
| uc-queue-id       | Indicates the unicast queue ID.                |
| mc-queue-id       | Indicates the multicast queue ID.              |
| minimum-bandwidth | Indicates the minimum bandwidth configuration. |

|                                                                            |                                                                                                            |
|----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
|                                                                            | The unit is Kbps.                                                                                          |
| maximum-bandwidth                                                          | Indicates the maximum bandwidth configuration. The unit is Kbps.                                           |
| Total queue minimum-bandwidth<br>Total queue maximum-bandwidth             | Indicates the total bandwidth of minimum and maximum when both unicast and multicast queues are displayed. |
| Total ucast-queue minimum-bandwidth<br>Total ucast-queue maximum-bandwidth | Indicates the total bandwidth of minimum and maximum when only unicast queue is displayed.                 |
| Total mcast-queue minimum-bandwidth<br>Total mcast-queue maximum-bandwidth | Indicates the total bandwidth of minimum and maximum when only multicast queue is displayed.               |

**Description**

## 2.30 show qos mc-queue cos-map

This command is used to display the mapping between multicast queues and priorities.

**show qos mc-queue cos-map**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | -         | -           |

**Defaults** -

**Command Mode** Privileged EXEC mode, global configuration mode or interface configuration mode.

**Usage Guide** -

**Configuration Examples** The following example displays the mapping between multicast queues and priorities

```
Ruijie# show qos mc-queue cos-map
Cos to multicast queue map:
Cos      Queue id
-----  -
0        1
1        1
```

|   |   |
|---|---|
| 2 | 1 |
| 3 | 1 |
| 4 | 2 |
| 5 | 2 |
| 6 | 2 |
| 7 | 3 |

| Related Commands | Command         | Description     |
|------------------|-----------------|-----------------|
|                  | <b>Cos</b>      | Cos value       |
|                  | <b>Queue id</b> | Queue ID of Cos |

**Platform** N/A

**Description**

## 2.31 show qos mc-queue scheduler

This command is used to display the scheduling algorithm for multicast queues.

**show qos mc-queue scheduler [ interfaces *interface-id* ]**

| Parameter          | Parameter                                | Description                |
|--------------------|------------------------------------------|----------------------------|
| <b>Description</b> | <b>interfaces</b><br><i>interface-id</i> | Interface to be displayed. |

**Defaults** -

**Command Mode** Privileged EXEC mode, global configuration mode or interface configuration mode.

**Usage Guide** -

**Configuration Examples** The following example displays the scheduling algorithm for multicast queues.

```
Ruijie# show qos mc-queue scheduler
Multicast queue scheduler:
Interface GigabitEthernet 0/0 :
    Strict Priority

Interface GigabitEthernet 0/1 :
    Strict Priority

Interface GigabitEthernet 0/2 :
```

```

Weighted Round Robin
Queue id      Weight
-----      -
1             1
2             2
3             4
    
```

| Related Commands | Command                                                      | Description                                                                      |
|------------------|--------------------------------------------------------------|----------------------------------------------------------------------------------|
|                  | <b>qos mc-queue scheduler mode {sp   wrr}</b>                | This command is used to configure the scheduling algorithm for multicast queues. |
|                  | <b>qos mc-queue scheduler weight weight1 weight2 weight3</b> | This command is used to configure the WRR algorithm weight for multicast queues. |

**Platform** N/A  
**Description**

## 2.32 show queueing wred interface

Use this command to display WRED settings on the interface.

**show queueing wred interface** *interface-id*

| Parameter Description | Parameter           | Description    |
|-----------------------|---------------------|----------------|
|                       | <i>interface-id</i> | Interface name |

**Defaults** None

**Command mode** Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example displays the WRED settings on interface GigabitEthernet 0/1.

```

Ruijie#show queueing wred interface gigabitEthernet 0/1
-----
qid  min_1  prob_1  min_2  prob_2
-----
1    100    60      80     80
2    100    60      80     80
3    100    60      80     80
4    100    60      80     80
5    100    60      80     80
    
```

```

6   100  60      80   80
7   100  60      80   80
8   100  60      80   80

-----
cos  qid  threshold_id
-----
0   1    1
1   2    1
2   3    1
3   4    1
4   5    1
5   6    1
6   7    1
7   8    1
    
```

The fields in the output of this command are described in the following table.

| Field                | Description                                                        |
|----------------------|--------------------------------------------------------------------|
| qid                  | Indicates the queue ID.                                            |
| cos qid threshold_id | Indicates the mapping of CoS value, queue ID and threshold number. |

**Related Commands**

| Command | Description |

| N/A.    | N/A.        |

**Platform Description**

N/A.

### 2.33 show virtual-group

Use this command to display the member port in the virtual group.

**show virtual-group** [ *virtual-group-number* | **summary** ]

**Parameter Description**

| Parameter                   | Description                                       |
|-----------------------------|---------------------------------------------------|
| <i>virtual-group-number</i> | Virtual group number. The range is from 1 to 128. |
| <b>summary</b>              | Displays the member port in all virtual groups.   |

**Defaults**

N/A

**Command Mode**

Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide** N/A

**Configuration** The following example displays the member port in all virtual groups.

**Examples**

```
Ruijie# show virtual-group summary

virtual-group      member
-----
1                  Gi0/1 Gi0/2
2                  Gi0/0
```

The fields in the output of this command are described in the following table.

| Field         | Description                                     |
|---------------|-------------------------------------------------|
| virtual-group | Indicates the virtual group number.             |
| member        | Indicates the member port in the virtual group. |

**Related**

| N/A     | N/A         |

**Platform** N/A

**Description**

## 2.34 virtual-group

Use this command to create a virtual group in global configuration mode.

Use this command to configure add an interface to a virtual group in interface configuration mode.

Use the **no** or **default** form of this command to remove a virtual group in global configuration mode.

Use the **no** or **default** form of this command to remove an interface from a virtual group in interface configuration mode.

**virtual-group** *virtual-group-number*

**no virtual-group** *virtual-group-number*

**default virtual-group** *virtual-group-number*

**Parameter**

**Description**

| Parameter                   | Description                                       |
|-----------------------------|---------------------------------------------------|
| <i>virtual-group-number</i> | Virtual group number. The range is from 1 to 128. |

**Defaults**

No virtual group is configured, or no interface is added to a virtual group, by default.

**Command**

Interface configuration mode, global configuration mode.

**Mode**

**Usage Guide**

The member port added to the virtual group must be a physical port or an aggregate port member.

The member ports of a virtual group must be on the same module of a chassis switch or on the same box switch.

**Configuration** The following example sets the interface gigabitEthernet 1/3 as the member of virtual group 3:

**Examples**

```
Ruijie(config)# interface gigabitEthernet 1/3
Ruijie(config-if)# virtual-group 3
```

## 2.35 wrr-queue bandwidth

Use this command to set the WRR weight ratio. Use the **no** or **default** form of this command to restore the default setting.

**wrr-queue bandwidth** *weight1 ... weight8*

**no wrr-queue bandwidth**

**default wrr-queue bandwidth**

| Parameter          | Parameter                | Description                                                                                                                                                                                                                                                   |
|--------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <i>weight1...weight8</i> | 8 queue weights. The default queue weight ratio is 1:1:1:1:1:1:1:1.<br>For the products supporting the SP scheduling policy, the weight range is from 0 to 15.<br>For the products not supporting the SP scheduling policy, the weight range is from 1 to 15. |

**Defaults** The default queue weight ratio is 1:1:1:1:1:1:1:1.

**Command Mode** Global/Interface configuration mode

**Usage Guide** If the weight value is 0, the SP scheduling policy is applied.

**Configuration Examples** The following example configures the WRR queue weight ratio to 1:1:1:1:2:2:4:8.

**Examples**

```
Ruijie(config)# wrr-queue bandwidth 1 1 1 1 2 2 4 8
```

**Description**

## 2.36 wrr-queue cos-map

Use this command to map the CoS value to a threshold for a specified queue. Use the **no** or **default** form of this command to restore the default settings

**wrr-queue cos-map** *threshold\_id* *cos1* [*cos2* [*cos3* [*cos4* [*cos5* [*cos6* [*cos7* [*cos8* ]]]]]]]]

**no wrr-queue cos-map** *threshold\_id*

**default wrr-queue cos-map** *threshold\_id*

**Parameter Description**

| Parameter           | Description                                                                               |
|---------------------|-------------------------------------------------------------------------------------------|
| <i>threshold_id</i> | Threshold number. The range is from 1 to 2. Up to two threshold values can be configured. |
| <i>cos_N</i>        | CoS value. The range is from 0 to 7. Up to 8 CoS values can be configured.                |

**Defaults** All CoS values are mapped to the threshold 1.

**Command mode** Interface configuration mode.

**Usage Guide** DSCP-threshold mapping can be enabled by mapping DSCP-CoS to CoS-threshold. When all CoS values are mapped to one threshold on the interface, it changes the enabled WRED to RED.

**Configuration Examples** The following example enters the interface GigabitEthernet 1/3 to map CoS 1, 2 to threshold 2.

```
Ruijie(config)# interface gigabitethernet 1/3
Ruijie(config-if-GigabitEthernet 1/3)#wrr-queue cos-map 2 1 6
```

**Related Commands**

| Command                                                 | Description                                       |
|---------------------------------------------------------|---------------------------------------------------|
| <b>show queueing wred interface</b> <i>interface-id</i> | Displays the WRED configuration on the interface. |

**Platform** N/A.  
**Description**

## 2.37 wrr-queue random-detect min-threshold

Use this command to configure the minimum WRED drop threshold. Use the **no** or **default** form of this command to restore the default WRED drop threshold.

**wrr-queue random-detect min-threshold** *queue\_id* *thr1* [ *thr2* ]

**no wrr-queue random-detect min-threshold** *queue\_id*

**default wrr-queue random-detect min-threshold** *queue\_id*

| Parameter Description | Parameter       | Description                                                                               |
|-----------------------|-----------------|-------------------------------------------------------------------------------------------|
|                       | <i>queue_id</i> | Queue ID.                                                                                 |
|                       | <i>thrN</i>     | Up to two threshold values can be configured. The threshold value range is from 1 to 100. |

**Defaults** Two threshold values are configured, and the default threshold values are 100 and 80.

**Command mode** Interface configuration mode.

**Usage Guide** Because the maximum value of the configuration range is equal to the current higher threshold, you need to pay attention to the setting of the higher threshold when configuring the lower threshold.

**Configuration** The following example configures the low WRED drop thresholds to 60 and 70 for queue 1.

### Examples

```
Ruijie(config)# interface gigabitethernet 1/3
Ruijie(config-if-GigabitEthernet 1/3)# wrr-queue random-detect min-threshold
1 60 70
```

**Platform** N/A.  
**Description**

## 2.38 wrr-queue random-detect probability

Use this command to configure the WRED packet drop probability. Use the **no** or **default** form of this command to restore the WRED packet drop probability.

**wrr-queue random-detect probability** *queue\_id* *prob1* [ *prob2* ]

**no wrr-queue random-detect probability** *queue\_id*

**default wrr-queue random-detect probability** *queue\_id*

| Parameter Description | Parameter       | Description                                                                                 |
|-----------------------|-----------------|---------------------------------------------------------------------------------------------|
|                       | <i>queue_id</i> | Queue ID.                                                                                   |
|                       | <i>proN</i>     | Up to two probability values can be configured. The threshold value range is from 1 to 100. |

**Defaults** Two packet drop probability values are configured, and the default probability values are 100 and 80.

**Command mode** Interface configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example configures the WRED packet drop values to 50 and 70 for queue 1.

```
Ruijie(config)# interface gigabitethernet 1/3
Ruijie(config-if-GigabitEthernet 1/3)# wrr-queue random-detect probability 1
50 70
```

## 3 MMU Commands

### 3.1 mmu buffer-mode

Use this command to configure global buffer mode.

**mmu buffer-mode { normal | burst-enhance | qos-enhance | flowctrl-enhance }**

Use the **no** form of this command to restore the default setting.

**no mmu buffer-mode**

| Parameter Description | Parameter               | Description              |
|-----------------------|-------------------------|--------------------------|
|                       | <b>normal</b>           | Normal buffer mode       |
|                       | <b>burst-enhance</b>    | Burst enhancement        |
|                       | <b>qos-enhance</b>      | QoS enhancement          |
|                       | <b>flowctrl-enhance</b> | Flow control enhancement |

**Defaults** The default buffer mode varies from product.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Examples** The following example configures the normal buffer mode.

```
Ruijie# mmu buffer-mode normal
```

**Platform Description** N/A

### 3.2 clear queue-buffer peaked

Use this command to clear the historical peak value of the queue buffer.

**clear queue-buffer peaked**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       |             |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** N/A

**Configuration** The following example clears the historical peak value of the buffer.

**Examples**

```
Ruijie# clear queue-buffer peaked
Ruijie#
```

**Platform Description** N/A

### 3.3 clear queue-counters

Use this command to clear queue statistics.

**clear queue-counter** [*interface interface \_id*]

| Parameter Description | Parameter           | Description |
|-----------------------|---------------------|-------------|
|                       | <i>interface_id</i> | Port Number |

**Command Mode** Privileged EXEC mode

**Default Level** 14

**Usage Guide** N/A

**Configuration** The following example clears all queue statistics.

**Examples**

```
Ruijie# clear queue-counter
Ruijie#
```

The following example clears queue statistics of an interface.

```
Ruijie# clear queue-counter Interface TenGigabitEthernet 1/9
Ruijie#
```

**Platform Description** N/A

### 3.4 mmu usage-warn-limit

Use this command to configure the usage warning threshold.

**mmu usage-warn-limit** [{ **unicast** } { *queue-id1* [*queue-id2* [*queue-idN*]]] **set** *value*

Use the **no** form of this command to restore the default setting.

**no mmu usage-warn-limit**

| Parameter Description | Parameter           | Description                                             |
|-----------------------|---------------------|---------------------------------------------------------|
|                       | <b>unicast</b>      | Performs buffer management on the output unicast queue. |
|                       | <i>queue-idN</i>    | Queue ID                                                |
|                       | <i>priority-idN</i> | Priority group ID                                       |
|                       | <i>value</i>        | Usage warning threshold.                                |

**Defaults** The default threshold is 0.

**Command Mode** Global configuration mode/Interface configuration mode

**Default Level** 14

**Usage Guide** If the buffer usage for the port group exceeds the global threshold, a warning log is printed. If the buffer usage for the queue exceeds the queue threshold, a warning log is printed. To avoid producing excessive logs, the warning log for a port group/queue is printed only once within 30 seconds.

**Configuration Examples** The following example sets the usage warning threshold globally.

```
Ruijie#config
Ruijie(config)# mmu usage-warn-limit set 90
```

The following example sets the usage warning threshold for unicast queue 3 and 8 to 80%.

```
Ruijie#config
Ruijie(config)# int te1/1
Ruijie(config-if)# mmu usage-warn-limit unicast 3 8 set 80
```

**Platform Description** N/A

### 3.5 mmu queue-guarantee

Use this command to configure the guaranteed buffer.

**mmu queue-guarantee output** { **unicast** } { *queue-id1* [*queue-id2* [*queue-idN*]] { **set** *value*

Use the **no** form of this command to restore the default setting.

**no mmu queue-guarantee output { unicast }**

| Parameter Description | Parameter        | Description                                                 |
|-----------------------|------------------|-------------------------------------------------------------|
|                       | <b>output</b>    | Performs buffer management on the output queue.             |
|                       | <b>unicast</b>   | Performs buffer management on the output unicast queue.     |
|                       | <i>queue-idN</i> | Queue ID                                                    |
|                       | <i>value</i>     | Sets the number of guaranteed buffer, in the unit of cells. |

**Defaults** The default varies with different products.

**Command Mode** Interface configuration mode

**Default Level** 14

**Usage Guide** This command is executed in different ways on different devices.

**Configuration Examples** The following example configures guaranteed buffer for unicast queue.

```
Ruijie#config
Ruijie(config)# interface tenGigabitEthernet 1/9
Ruijie(config-if)#mmu queue-guarantee ouput unicast 1 3 7 8 set 15
Ruijie(config-if)#exit
Ruijie(config)#exit
Ruijie#
```

**Platform Description** N/A

### 3.6 mmu queue-thredshold

Use this command to configure the shared buffer.

**mmu queue-thredshold output { unicast } { queue-id1 [queue-id2 [queue-idN] ] } set th%**

Use the **no** form of this command to restore the default setting.

**no mmu queue-thredshold output { unicast }**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                  |                                                         |
|------------------|---------------------------------------------------------|
| <b>output</b>    | Performs buffer management on the output queue.         |
| <b>unicast</b>   | Performs buffer management on the output unicast queue. |
| <i>queue-idN</i> | Queue ID                                                |
| <i>th%</i>       | Total shared buffer * threshold = Available buffer      |

**Defaults** The default varies with different products.

**Command Mode** Interface configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration** The following example configures shared buffer for unicast queue.

**Examples**

```
Ruijie#config
Ruijie(config)# interface tenGigabitEthernet 1/9
Ruijie(config-if)#mmu queue-threshold ouput unicast 1 3 7 8 set 80
Ruijie(config-if)#exit
```

**Platform Description** N/A

### 3.7 mmu fc-threshold

Use this command to configure the inbound buffer threshold.

**mmu fc-threshold set** *th%*

Use the **no** form of this command to restore the default setting.

**no mmu fc-threshold**

| Parameter Description | Parameter  | Description                                           |
|-----------------------|------------|-------------------------------------------------------|
|                       | <i>th%</i> | Indicates the percentage of inbound buffer threshold. |

**Defaults** The default varies with different products.

**Command Mode** Interface configuration mode

**Usage Guide** This command is executed in different ways on different devices.  
This command only takes effect when flow control/PFC is enabled.

**Configuration** The following example configures inbound buffer threshold of priority group.

**Examples**

```
Ruijie#config
Ruijie(config)# interface tenGigabitEthernet 0/9
Ruijie(config-if)#mmu fc-threshold set 80
Ruijie(config-if)#exit
```

**Platform**

N/A

**Description**

### 3.8 show queue-buffer interface

Use this command to display buffer usage of interfaces.

**show queue-buffer interface** { *interface-id*}

| Parameter Description | Parameter           | Description |
|-----------------------|---------------------|-------------|
|                       | <i>interface-id</i> | Interface   |

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Examples** The following example displays buffer usage of the specified interface based on output queue.

```
Ruijie(config)#show queue-buffer interface hundredGigabitEthernet 0/1
Interface HundredGigabitEthernet 0/1:
Slice 1:
Type      Queue  Used cells  Available cells  Usage  Usage warn limit  Usage warn count  Peaked
cells
Unicast   1      42288      0                100%  0%                0
42288
Unicast   2      0          42280            0%    0%                0                0
Unicast   3      0          42280            0%    0%                0                0
Unicast   4      0          42280            0%    0%                0                0
Unicast   5      0          42280            0%    0%                0                0
Unicast   6      0          42280            0%    0%                0                0
Unicast   7      0          42280            0%    0%                0                0
Unicast   8      0          42280            0%    0%                0                0

| Field           | Description                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------|
| Slice           | No. of the module on the chip for buffer division                                             |
| Type            | Queue type, including unicast queue and multicast queue                                       |
| Queue           | Queue No., ranging from 1 to 8 by default and can be switched to 0 to 7 through configuration |
| Used cells      | Size of the occupied buffer in a queue, in the unit of cell                                   |
| Available cells | Size of the available buffer in a queue, in the unit of cell                                  |

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| Usage                  | Percentage of the occupied buffer in a queue                           |
| Usage warn limit       | Buffer usage warning threshold of a specific port group or queue       |
| Usage warn count       | Number of times that the occupied buffer exceeds the warning threshold |
| Peaked cells           | Historical peak value of the used buffer                               |
| Slot                   | Slot No. of the line card                                              |
| PortGroup              | Port group No., starting from 1                                        |
| Total cells            | Total buffer on a specified slice                                      |
| Total usage            | Percentage of the occupied buffer on a specified slice                 |
| Static used cells      | Size of the occupied guarantee buffer on a specified slice             |
| Global shared cells    | Total shared buffer on a specified slice                               |
| Available shared cells | Size of the available shared buffer on a specified slice               |

The following example displays the buffer queue information of all interfaces.

```

### 3.9 show queue-counter interface

Use this command to display buffer queue statistics of interfaces.

**show queue-counter interface** *interface-id*

| Parameter Description | Parameter           | Description |
|-----------------------|---------------------|-------------|
|                       | <i>interface-id</i> | Interface   |

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Examples** The following example displays buffer queue statistics of the specified interface based on output queue.

```
Ruijie#show queue-counter interface gigabitEthernet 0/9
Interface HundredGigabitEthernet 4/1:
  Unicast
  Queue    Transmitted Bytes    Dropped Bytes    Frame Loss Rate(%)    Transmit Rate(bps)

# 1 REUP Commands

## 1.1 link state group

Use this command to add the port into the specified link state track group. The **no** form of this command is used to delete a port from the specified link state track group.

**link state group** *num* { **upstream** | **downstream** }

**no link state group**

| Parameter Description | Parameter         | Description                                                                |
|-----------------------|-------------------|----------------------------------------------------------------------------|
|                       | <i>num</i>        | ID of the link state track group.                                          |
|                       | <b>upstream</b>   | Configures the port to be an upstream port in the link state track group.  |
|                       | <b>downstream</b> | Configures the port to be a downstream port in the link state track group. |

**Defaults** The port is not added into any link state track group.

**Command Mode** Interface configuration mode.

**Usage Guide** First create a link state track group and then add a port into the specified link state track group.

**Configuration Examples** The following example shows how to add the port fa0/2 into the link state track group:

```
Ruijie(config)# link state track 1
Ruijie(config)# interface fa 0/2
Ruijie(config-if)# link state group 1 upstream
```

| Related Commands | Command                 | Description                       |
|------------------|-------------------------|-----------------------------------|
|                  | <b>link state track</b> | Enables a link state track group. |

**Platform Description** N/A.

## 1.2 link state track

Use this command to enable the link state track group. The **no** form of this command is used to disable a link state track group

**link state track** [ *num* | **up-delay** *timer* ]

**no link state track** [ *num* ]

| Parameter Description | Parameter             | Description                                                        |
|-----------------------|-----------------------|--------------------------------------------------------------------|
|                       | <i>num</i>            | Interface ID of the link aggregation group.                        |
|                       | <b>up-delay timer</b> | Delay time for link up. By default, there is no delay for link up. |

**Defaults** N/A.

**Command Mode** Global configuration mode.

**Usage Guide** First create a link state track group and then add a port into the specified link state track group.

**Configuration Examples** The following example shows how to create a link state track group:

```
Ruijie(config)# link state track 1
```

The following example shows how to create a link state track group and set the down link to become up after 30s when uplink becomes up:

```
Ruijie(config)# link state track 1 up-delay 30
```

| Related Commands | Command                 | Description                                            |
|------------------|-------------------------|--------------------------------------------------------|
|                  | <b>link state group</b> | Adds the port to the specified link state track group. |

**Platform** N/A.

**Description**

### 1.3 mac-address-table move update max-update-rate

Use this command to configure the maximum number of MAC address update packets sent per second.

**mac-address-table move update max-update-rate** *pkts-per-second*

**no mac-address-table move update max-update-rate**

| Parameter Description | Parameter              | Description                                                                                                                |
|-----------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------|
|                       | <i>pkts-per-second</i> | The maximum number of MAC address update packets sent per second. It ranges from 0 to 32000, and the default value is 150. |

**Defaults** A maximum of 150 MAC address update packets are sent per second.

**Command** Global configuration mode.

**Mode**

**Usage Guide** When a link is switched, REUP sends a certain number of MAC address update packets to an uplink device in every second to recover downlink data transmission of the uplink device.

**Configuration Examples** The following example shows how to configure the maximum number of MAC address update packets sent per second:

```
Ruijie(config)# mac-address-table move update max-update-rate 20
```

**Related Commands**

| Command | Description |
|---------|-------------|
| N/A.    | N/A.        |

**Platform Description** N/A.

## 1.4 mac-address-table move update receive

Use this command to enable REUP to receive the mac-address-table update messages.

**mac-address-table move update receive**

**no mac-address-table move update receive**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A.      | N/A.        |

**Defaults** Disabled.

**Command Mode** Global configuration mode.

**Usage Guide** The dual link backup switchover will lead to the loss of downstream data flow, for the MAC address for the uplink switch has not been updated in time. Therefore, it is necessary to update the MAC address table of the uplink switch, to reduce the loss of L2 data flow. You need to enable the switch of receiving the MAC address update messages on the uplink switch.

**Configuration Examples** Ruijie(config)# mac-address-table move update receive

**Related Commands**

| Command                                      | Description                                                     |
|----------------------------------------------|-----------------------------------------------------------------|
| <b>mac-address-table move update transit</b> | Enables REUP to transmit the mac-address-table update messages. |

**Platform** N/A.

**Description**

## 1.5 mac-address-table move update receive vlan

Use this command to configure the VLANs processing MAC address update packets.

**mac-address-table move update receive vlan** *vlan-range*

**no mac-address-table move update receive vlan** *vlan-range*

| Parameter   | Parameter         | Description                                               |
|-------------|-------------------|-----------------------------------------------------------|
| Description | <i>vlan-range</i> | Range of the VLANs processing MAC address update packets. |

**Defaults** All VLANs process MAC address update packets.

**Command** Global configuration mode.

**Mode**

**Usage Guide** This command can be used to disable some VLANs from processing MAC address update packets. VLANs disabled from processing MAC address update packets can still recover downlink data transmission of the uplink device using MAC address update packets, but the capability to provide convergence on link failure will be degraded.

**Configuration** The following example configures VLANs processing MAC address update packets:

**Examples**

```
Ruijie(config)# no mac-address-table move update receive vlan 20
```

| Related Commands | Command                                      | Description                                         |
|------------------|----------------------------------------------|-----------------------------------------------------|
|                  | <b>mac-address-table move update receive</b> | Enables REUP to receive MAC address update packets. |

**Platform** N/A.

**Description**

## 1.6 mac-address-table move update transit

Use this command to enable REUP to transmit the mac-address-table update messages.

**mac-address-table move update transit**

**no mac-address-table move update transit**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A.      | N/A.        |

**Defaults** Disabled.

**Command Mode** Global configuration mode.

**Usage Guide** In order to reduce the link switchover and the loss of the downstream data flow, it is necessary to enable the switch of receiving the MAC address update messages on the uplink switch.

**Configuration Examples**

```
Ruijie(config)# mac-address-table move update transit
```

**Related Commands**

|---------------------------------------------------|-----------------------------------------------------------------|
| <b>mac-address-table move update transit vlan</b> | Enables REUP to transmit the mac-address-table update messages. |

**Platform** N/A.

**Description**

## 1.7 mac-address-table move update transit vlan

Use this command to enable REUP to transmit the mac-address update messages.

**mac-address-table move update transit vlan** *vid*

**no mac-address-table move update transit vlan**

**Parameter Description**

| Parameter  | Description                                             |
|------------|---------------------------------------------------------|
| <i>vid</i> | ID of the VLAN transmitting MAC address update packets. |

**Defaults** Transmit the MAC-address update messages in the default VLAN on the port.

**Command Mode** Interface configuration mode.

**Usage Guide** When a link is switched, the VLAN enabled to transmit MAC address update packets will send MAC address update packets to its uplink device.

**Configuration Examples** The following example configures VLANs transmitting MAC address update packets:

```
Ruijie(config)# mac-address-table move update transit
```

**Related Commands**

|--|------------------------------------|
|  | mac-address-table update messages. |
|--|------------------------------------|

**Platform** N/A.

**Description**

## 1.8 mac-address-table update group

Use this command to set the mac-address-table update group.

**mac-address-table update group** [ *group-num* ]

**no mac-address-table update group**

| Parameter   | Parameter        | Description                            |
|-------------|------------------|----------------------------------------|
| Description | <i>group-num</i> | The mac-address-table update group ID. |

**Defaults** By default, no mac-address-table update group is configured.

**Command** Interface configuration mode.

**Mode**

**Usage Guide** In order to reduce the flood due to the MAC address update and the influence on the normal data transmission of the switch, Ruijie products add a configuration of MAC address update group. Only if all the interfaces are added to a MAC address update group, the downstream data transmission be restored rapidly.

**Configuration** Ruijie(config-if)# mac-address-table update group 2

**Examples**

| Related Commands | Command                                           | Description                                              |
|------------------|---------------------------------------------------|----------------------------------------------------------|
|                  | <b>show mac-address-table update group detail</b> | Displays the mac-address-table update group information. |

**Platform** N/A.

**Description**

## 1.9 switchport backup interface *interface-id*

Use this command to configure the REUP dual link backup interface.

**switchport backup interface** *interface-id*

**no switchport backup**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |                     |                                  |
|--------------------|---------------------|----------------------------------|
| <b>Description</b> |                     |                                  |
|                    | <i>interface-id</i> | Interface ID of the backup link. |

**Defaults** N/A.

**Command** Interface configuration mode.

**Mode**

**Usage Guide** Enter the primary interface configuration mode, the *interface-id* in the parameter is for the backup interface. When the active link fails, the backup link transmission is restored rapidly

**Configuration Examples** The following example shows how to set the dual link backup, with fa 0/1 and fa 0/2 as primary interface and backup interface:

```
Ruijie(config)# interface fa 0/1
Ruijie(config-if)# switchport backup interface fa 0/2
```

| <b>Related Commands</b> | Command                                 | Description                                                |
|-------------------------|-----------------------------------------|------------------------------------------------------------|
|                         | <b>show interface switchport backup</b> | Displays the dual link backup configuration on the switch. |

**Platform** N/A.

**Description**

## 1.10 switchport backup interface preemption

Use this command to configure the REUP link preemption function.

**switchport backup interface** *interface-id* **preemption mode** { **forced** | **bandwidth** | **off** }

**switchport backup interface** *interface-id* **preemption delay** *delay-time*

**no switchport backup interface** *interface-id* **preemption delay**

| <b>Parameter Description</b> | Parameter           | Description                          |
|------------------------------|---------------------|--------------------------------------|
|                              | <i>interface-id</i> | The interface id of the backup link. |
|                              | <i>delay-time</i>   | The preemption delay time.           |

**Defaults** The preemption function is disabled by default.

The default preemption delay time is 35s.

**Command** Interface configuration mode.

**Mode**

**Usage Guide** The preemption mode includes **forced**, **bandwidth** and **off**. In the **bandwidth** preemption mode, the interface with high bandwidth has priority over other interfaces to transmit the data. In the **forced**

preemption mode, the primary has priority over backup interfaces to transmit the data. No preemption event occurs in the **off** preemption mode. By default, the preemption mode is off.

The preemption delay refers to the delay time of the link switchover after the restoration of the link failure.

**Configuration Examples** The following example shows how to set the dual link backup, with fa 0/1 and fa 0/2 as the primary interface and backup interface, set the bandwidth preemption mode and 40s preemption delay:

```
Ruijie(config)# interface fa 0/1
Ruijie(config-if)# switchport backup interface fa 0/2
preemption mode bandwidth
Ruijie(config-if)# switchport backup interface fa 0/2
preemption delay 40
```

**Related Commands**

| Command                                 | Description                                  |
|-----------------------------------------|----------------------------------------------|
| <b>show interface switchport backup</b> | Displays the dual link backup configuration. |

**Platform Description** N/A.

## 1.11 switchport backup interface prefer

Use this command to configure VLAN load balancing on a link. The **no** form of this command is used to delete the configured VLAN load strategy.

**switchport backup interface** *interface-id* **prefer instance** *instance-range*

**no switchport backup interface** *interface-id* **prefer**

| Parameter Description | Parameter             | Description                                        |
|-----------------------|-----------------------|----------------------------------------------------|
|                       | <i>interface-id</i>   | Interface ID of the backup link.                   |
|                       | <i>instance-range</i> | Instance range of loading on the backup interface. |

**Defaults** No VLAN load on the backup interface.

**Command Mode** Interface configuration mode.

**Usage Guide** MSTP instance mapping can be used to modify the mapping between an instance and a VLAN.

**Configuration Examples** The following example configures VLAN load balancing on dual links.

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if)# switchport backup interface gigabitEthernet 0/2 prefer
instance 1
```

| Related Commands | Command                                 | Description                                                   |
|------------------|-----------------------------------------|---------------------------------------------------------------|
|                  | <b>show interface switchport backup</b> | Displays the configuration of dual-link backup on the switch. |
|                  | <b>spanning-tree mst configuration</b>  | Configures MSTP instances.                                    |

**Platform** N/A.  
**Description**

## 1.12 show interfaces switchport backup

Use this command to display the dual link backup information on the interfaces.

**show interfaces** [ *interface-id* ] **switchport backup** [ *detail* ]

| Parameter Description | Parameter           | Description                                                   |
|-----------------------|---------------------|---------------------------------------------------------------|
|                       | <i>interface-id</i> | The interface id of the dual link backup.                     |
|                       | <b>detail</b>       | Displays the detailed information about the dual link backup. |

**Defaults**

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A.

**Configuration Examples**

```
Ruijie # show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface      Backup Interface      State
-----
Gi0/23                Gi0/24                Active Up/Backup Standby
Interface Pair : Gi0/23, Gi0/24
Preemption Mode : Off
Preemption Delay : 35 seconds
Bandwidth : Gi0/23(1000 Mbits), Gi0/24(1000 Mbits)
```

| Related Commands | Command | Description |
|------------------|---------|-------------|

**Platform** N/A.  
**Description**

## 1.13 show link state group

Use this command to display the information of a link state track group.

**show link state group**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A.

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A.

**Configuration** The following example displays the link state track group:

**Examples**

```
Ruijie # show link state group
Link State Group:1 Status: Enabled, UP
Upstream Interfaces :Gi0/1(Up)
Downstream Interfaces :Gi0/3(Dwn), Gi0/4(Dwn)
Link State Group:2 Status: Disabled, Down
Upstream Interfaces :
Downstream Interfaces :
(Up):Interface up (Dwn):Interface Down (Dis):Interface disabled
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A.    | N/A.        |

**Platform** N/A.

**Description**

## 1.14 show mac-address-table move update

Use this command to display the statistics about the MAC address updates tranceived on the interface.

**show mac-address-table move update**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A.

```
Ruijie#show mac-address-table move update
Mac address table move update status:
Transit:disable
Receive:disable
Max-update-rate:150
Receive vlan:1-4094

Pair: Ag1,Ag2
Members          Status    Transit Count    Transit VLAN    Last Transit

**Platform Description** N/A.

## 2 RLDP Commands

### 2.1 rldp detect-interval

Use this command to configure the interval at which the RLDP sends the detection message on the port. Use the **no** form of this command to restore the default value.

**rldp detect-interval** *interval*

**no rldp detect-interval**

| Parameter Description | Parameter       | Description                                     |
|-----------------------|-----------------|-------------------------------------------------|
|                       | <i>interval</i> | Detection interval in the range 2 to 15 seconds |

**Defaults** 3 seconds.

**Command Mode** Global configuration mode.

**Usage Guide** In the environment where STP is enabled, it is recommended that the product of interval multiplying the maximum number of detections is less than the topology convergence time of STP.

**Configuration Examples** The following example shows how to set the detection interval as 5s:

```
Ruijie(config)# rldp detect-interval 5
```

| Related Commands | Command                | Description                            |
|------------------|------------------------|----------------------------------------|
|                  | <b>rldp detect-max</b> | Sets the maximum number of detections. |

**Platform** N/A.

**Description**

### 2.2 rldp detect-max

Use this command to set the maximum number of sending detection packets on the port. If the neighboring port does not respond when this detection number is exceeded, the link is considered faulty. Use the **no** form of this command to restore it to the default value.

**rldp detect-max** *num*

**no rldp detect-max**

| Parameter Description | Parameter  | Description                                       |
|-----------------------|------------|---------------------------------------------------|
|                       | <i>num</i> | Maximum number of detections in the range 2 to 10 |

- Defaults** 2.
- Command Mode** Global configuration mode.
- Usage Guide** This command is used together with the detection interval to specify the maximum number of detections.

**Configuration** The following example shows how to set the maximum number of detections as 5:

**Examples**

```
Ruijie(config)# rldp detect-max 5
```

| Related Commands | Command | Description                 |
|------------------|---------|-----------------------------|
|                  |         | <b>rldp detect-interval</b> |

**Platform** N/A.

**Description**

## 2.3 rldp enable

Use this command to enable RLDP globally. Use the **no** form of this command to disable the function.

**rldp enable**

**no rldp enable**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | N/A.        |

**Defaults** Disabled.

**Command Mode** Global configuration mode.

**Usage Guide** You can enable RLDP on the interface only when the global RLDP is enabled.

**Configuration** The following example shows how to enable RLDP:

**Examples**

```
Ruijie(config)# rldp enable
```

| Related Commands | Command | Description      |
|------------------|---------|------------------|
|                  |         | <b>rldp port</b> |

**Platform** N/A.

## Description

## 2.4 rldp neighbor-negotiation

Use this command to enable RLDP neighbor negotiation. Use the **no** form or **default** form of this command to restore the default setting.

**rldp neighbor-negotiation**  
**no rldp neighbor-negotiation**  
**default rldp neighbor-negotiation**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A.      | N/A.        |

**Defaults** RLDP neighbor negotiation is disabled by default.

**Command** Global configuration mode.

**Mode**

**Usage Guide** With neighbor negotiation enabled, RLDP unidirectional-/bidirectional-link detection starts only after the neighbor negotiation is successful. (Receiving the Prob message from the neighbor indicates the neighbor negotiation is successful.)

**Configuration** The following example shows how to enable RLDP neighbor negotiation:

**Examples**

```
Ruijie#config
Ruijie(config)#rldp neighbor-negotiation
```

| Related Commands | Command          | Description                            |
|------------------|------------------|----------------------------------------|
|                  | <b>rldp port</b> | Enables the RLDP function on the port. |

**Platform** N/A.

**Description**

## 2.5 rldp port

Use this command to enable RLDP on the port and specify detection type and troubleshooting method. Use the **no** form of this command to disable the function.

**rldp port { unidirection-detect | bidirection-detect | loop-detect } { warning | shutdown-svi | shutdown-port | block }**  
**no rldp port { unidirection-detect | bidirection-detect | loop-detect }**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

| Description                |                                             |
|----------------------------|---------------------------------------------|
| <b>unidirection-detect</b> | Sets unidirectional link detection.         |
| <b>bidirection-detect</b>  | Sets bidirectional link detection.          |
| <b>loop-detect</b>         | Sets loop detection type.                   |
| <b>warning</b>             | Warns the user.                             |
| <b>shutdown-svi</b>        | Shutowns the SVI the port belongs to.       |
| <b>shutdown-port</b>       | Shutowns the port.                          |
| <b>block</b>               | Disables learning and forwarding of a port. |

**Defaults** N/A

**Command** Interface configuration mode.

**Mode**

**Usage Guide** The RLDP detection on the port takes effect only when the global RLDP is enabled.

**Configuration Examples** The following example shows how to enable the RLDP detection and specify the failure treatment as **block**.

```
Ruijie(config)# interface GigabitEthernet 2/0/9
Ruijie(config-if-GigabitEthernet 2/0/9)# rldp port loop-detect block
```

| Related Commands | Command            | Description            |
|------------------|--------------------|------------------------|
|                  | <b>rldp enable</b> | Enables RLDP globally. |

**Platform** N/A.

**Description**

## 2.6 rldp reset

Use this command to make all the ports that have been handled using rldp shutdown or disable to perform RLDP detection again.

**rldp reset**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A.      | N/A.        |

**Defaults** N/A.

**Command** Privileged EXEC mode.

**Mode**

**Usage Guide** This command is used to recover the faulty port. The **errdisable recovery** can be also used for the purpose. For details, refer to the *Configuring Interface* chapter.

**Configuration** The example below demonstrates how to use this command:

**Examples** Ruijie# rldp reset

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  |         | rldp enable |

**Platform** N/A.

**Description**

## 2.7 show rldp

Use this command to display the RLDP information.

**show rldp [ interface *interface-id* ]**

| Parameter Description | Parameter | Description         |
|-----------------------|-----------|---------------------|
|                       |           | <i>interface-id</i> |

**Defaults** N/A.

**Command Mode** Privileged EXEC mode.

**Usage Guide** N/A.

**Configuration Examples** N/A.

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  |         | N/A.        |

**Platform** N/A.

**Description**

## 3 VRRP Commands

### 3.1 show vrrp

Use this command to display the VRRP information.

**show** [ **ipv6** ] **vrrp** [ **brief** | *group* ]

| Parameter          | Parameter    | Description                                      |
|--------------------|--------------|--------------------------------------------------|
| <b>Description</b> | <b>ipv6</b>  | (Optional) Applies to IPv6 VRRP.                 |
|                    | <b>brief</b> | (Optional) Displays the brief of the VRRP group. |
|                    | <i>group</i> | Number of the VRRP group to be displayed         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** If no optional parameter is used, the information of all VRRP groups is displayed.

**Configuration Examples** The following example displays the information of all VRRP groups.

```
Ruijie# show vrrp
GigabitEthernet 0/0 - Group 1
State is Backup
Virtual IP address is 192.168.201.1 configured
Virtual MAC address is 0000.5e00.0101
Advertisement interval is 3 sec
Preemption is enabled
min delay is 0 sec
Priority is 100
Master Router is 192.168.201.213 , priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 10.82 sec
GigabitEthernet 0/0 - Group 2
State is Master
Virtual IP address is 192.168.201.2 configured
Virtual MAC address is 0000.5e00.0102
Advertisement interval is 3 sec
Preemption is enabled
min delay is 0 sec
Priority is 120
Master Router is 192.168.201.217 (local), priority is 120
Master Advertisement interval is 3 sec
```

```

Master Down interval is 10.59 sec
Ruijie#show ipv6 vrrp
GigabitEthernet 0/13 - Group 1
  State is Master
  Virtual IPv6 address is as follows:
    FE80::2
    1::2
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 1 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is FE80::1 (local), priority is 100
  Master Advertisement interval is 1 sec
  Master Down interval is 3.60 sec

```

| Related Commands | Command                                                          | Description                                                              |
|------------------|------------------------------------------------------------------|--------------------------------------------------------------------------|
|                  | <code>vrrp group ip <i>ipaddress</i> [ <b>secondary</b> ]</code> | Enables the VRRP function and set the IP address for the virtual device. |

**Platform** N/A

**Description**

## 3.2 show vrrp interface

Use this command to display the information of the VRRP on the interface.

`show [ ipv6 ] vrrp interface type number [ brief ]`

| Parameter          | Parameter           | Description                                                       |
|--------------------|---------------------|-------------------------------------------------------------------|
| <b>Description</b> | <code>ipv6</code>   | (Optional) Applies to IPv6 VRRP.                                  |
|                    | <code>type</code>   | Interface type                                                    |
|                    | <code>number</code> | Interface number                                                  |
|                    | <code>brief</code>  | (Optional) Displays the brief of the VRRP group on the interface. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the VRRP information on Ethernet interface E1/0.

```
Ruijie# show vrrp interface fastethernet 0/0
```

```

FastEthernet 0/0 - Group 1
State is Backup
Virtual IP address is 192.168.201.1 configured
Virtual MAC address is 0000.5e00.0101
Advertisement interval is 3 sec
Preemption is enabled
min delay is 0 sec
Priority is 100
Master Device is 192.168.201.213 , pritority is 120
Master Advertisement interval is 3 sec
Master Down interval is 9 sec
FastEthernet 0/0 - Group 2
State is Master
Virtual IP address is 192.168.201.2 configured
Virtual MAC address is 0000.5e00.0102
Advertisement interval is 3 sec
Preemption is enabled
min delay is 0 sec
Priority is 120
Master Device is 192.168.201.217 (local), priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 9 sec

```

| Related Commands | Command                                       | Description                                                             |
|------------------|-----------------------------------------------|-------------------------------------------------------------------------|
|                  | <b>vrrp group ip ip address [ secondary ]</b> | Enables the VRRP function and set the IP address for the virtual device |

**Platform** N/A  
**Description**

### 3.3 show vrrp packet statistics

Use this command to display the statistics of the VRRP packet transmission.

**show vrrp packet statistics** [ *interface-type interface-number* ]

| Parameter Description | Parameter               | Description               |
|-----------------------|-------------------------|---------------------------|
|                       | <i>interface-type</i>   | Interface type and number |
|                       | <i>interface-number</i> |                           |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the statistics of VRRP packet transmission on all interfaces.

**Examples**

```
Ruijie# show vrrp packet statistics

Total
  InReceives: 966043 packets, InOctets: 38641824, InErrors: 38826
  OutTransmits: 306079, OutOctets: 7798564
GigabitEthernet 3/0/1
  InReceives: 799665 packets, InOctets: 31986600, InErrors: 19657
  OutTransmits: 272931, OutOctets: 6675320
GigabitEthernet 3/0/2
  InReceives: 0 packets, InOctets: 0, InErrors: 0
  OutTransmits: 681, OutOctets: 16344
```

The following example displays the statistics of VRRP packets on the interface gigabitEthernet 3/0/1.

```
Ruijie#show vrrp packet statistics gigabitEthernet 3/0/1
GigabitEthernet 3/0/1
  InReceives: 799911 packets, InOctets: 31996440, InErrors: 19657
  OutTransmits: 273053, OutOctets: 6677760
```

| Related  | Command | Description |
|----------|---------|-------------|
| Commands | N/A     | N/A         |

**Platform** N/A

**Description**

### 3.4 vrrp accept\_mode

Use this command to enable the packet accepting function on the IPv6 VRRP virtual router.

Use the **no** form of this command to disable this function.

**vrrp ipv6 group accept\_mode**

**no vrrp ipv6 group accept\_mode**

| Parameter   | Parameter | Description       |
|-------------|-----------|-------------------|
| Description | group     | VRRP group number |

**Defaults** The master IPv6 VRRP is not allowed to accept packets whose destination IPv6 address is the IPv6 address of a virtual router. However, the NA and NS packets should be accepted regardless of the configuration of Accept\_Mode. Also, the master IPv6 VRRP virtual router in the owner state will accept and process any packets whose destination IPv6 address is the IPv6 address of a virtual router, regardless of the configuration of Accept\_Mode.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Configuration of the network interface is effective for the master virtual router.

 Only IPv6 VRRP has this configuration mode.

**Configuration** The following example enables the accept mode on the group 1.

**Examples**

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 enable
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 address 2001::2/64
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 FE80::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 2001::1
Ruijie(config-if-GigabitEthernet 0/0)# vrrp ipv6 1 accept_mode
```

**Platform** N/A

**Description**

### 3.5 vrrp authentication

Use this command to enable VRRP authentication.

Use the **no** form of this command to disable this function.

**vrrp group authentication string**

**no vrrp group authentication**

| Parameter          | Parameter     | Description                                                                   |
|--------------------|---------------|-------------------------------------------------------------------------------|
| <b>Description</b> | <i>group</i>  | VRRP group number                                                             |
|                    | <i>string</i> | String for the VRRP group authentication (within 8 bytes, plaintext password) |

**Defaults** This function is disabled by default. Even if the VRRP function is enabled, no authentication password is configured by default.

**Command** Interface configuration mode

**Mode****Usage Guide**

In a VRRP group, the same authentication password should be configured for routers. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3.

Authentication is abolished for VRRPv3 (IPv4 VRRP and IPv6 VRRP) packets. If VRRPv2 is chosen

for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

**Configuration** The following example sets the authentication password for VRRP group 1.

**Examples**

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 authentication x30dn78k
```

**Platform** N/A

**Description**

### 3.6 vrrp bfd (Interface Configuration Mode)

Use this command to enable BFD correlation for the specified IPv4 VRRP group.

Use the **no** form of this command to remove the BFD correlation for the specified IPv4 VRRP group.

**vrrp group bfd ip-address**

**no vrrp group bfd ip-address**

| Parameter   | Parameter         | Description         |
|-------------|-------------------|---------------------|
| Description | <i>group</i>      | VRRP group ID       |
|             | <i>ip-address</i> | Neighbor IP address |

**Defaults** By default, no BFD correlation is configured for the IPv4 VRRP group on the interface.

**Command** Interface configuration mode.

**Mode**

**Usage Guide** After the global BFD correlation for IPv4 VRRP is configured, the BFD correlation configuration for the IPv4 VRRP groups will be removed.

The IP address and BFD session of the interface must be configured before configuring the **vrrp bfd** command.

**Configuration** The following example enables BFD correlation for the VRRP group.

**Examples**

On Switch 1:

```
Ruijie#configure terminal
Ruijie(config)#interface vlan 1
Ruijie(config-if-VLAN 1)#ip address 1.1.1.2 255.255.255.0
Ruijie(config-if-VLAN 1)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-VLAN 1)#vrrp 1 ip 1.1.1.1
Ruijie(config-if-VLAN 1)#vrrp 1 bfd 1.1.1.3
```

On Switch 2:

```
Ruijie#configure terminal
```

```
Ruijie(config)#interface vlan 1
Ruijie(config-if-VLAN 1)#ip address 1.1.1.3 255.255.255.0
Ruijie(config-if-VLAN 1)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-VLAN 1)#vrrp 1 ip 1.1.1.1
Ruijie(config-if-VLAN 1)#vrrp 1 bfd 1.1.1.2
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A  
**Description**

### 3.7 vrrp bfd (Global Configuration Mode)

Use this command to enable the global BFD correlation for the IPv4 VRRP backup group to detect the master router status.

Use the **no** form of this command to remove the BFD correlation for IPv4 VRRP.

**vrrp bfd** *interface-type interface-number ip-address*

**no vrrp bfd**

| Parameter          | Parameter               | Description                         |
|--------------------|-------------------------|-------------------------------------|
| <b>Description</b> | <i>interface-type</i>   | Interface type and interface number |
|                    | <i>interface-number</i> |                                     |
|                    | <i>ip-address</i>       | Neighbor IP address                 |

**Defaults** By default, the global BFD correlation for IPv4 VRRP is disabled.

**Command Mode** Global configuration mode

**Usage Guide** After the global BFD correlation for IPv4 VRRP is configured, the BFD correlation configuration for the IPv4 VRRP groups will be removed.

The global BFD correlation for IPv4 VRRP configured later will override the earlier configuration.

The IP address and BFD session of the interface must be configured before configuring the vrrp bfd command.

The global IPv4 VRRP BFD session applies to the IPv4 VRRP router which consists of two devices only.

**Configuration Examples** The following example enables global BFD correlation for IPv4 VRRP.

```
Ruijie#configure terminal
Ruijie(config)#interface vlan 1
Ruijie(config-if-VLAN 1)#ip address 192.168.201.11 255.255.255.0
Ruijie(config-if-VLAN 1)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config-if-VLAN 1)#exit
```

```
Ruijie(config)# vrrp bfd vlan 1 192.168.201.10
```

**Platform** N/A  
**Description**

### 3.8 vrrp delay

Use this command to set the reload latency of the VRRP group on the interface.

Use the **no** form of this command to restore the default setting.

**vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* }

**no vrrp delay**

| Parameter          | Parameter                           | Description                                                                                                                                                                                 |
|--------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <b>minimum</b> <i>min-seconds</i>   | When the interface is up, VRRP group shall be reloaded after at least <i>min-seconds</i> .                                                                                                  |
|                    | <b>reload</b> <i>reload-seconds</i> | The reload latency of the VRRP group. If the configured <i>min-seconds</i> is greater than <i>reload-seconds</i> , the actual reload latency of the VRRP group will be <i>min-seconds</i> . |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

**Configuration Examples** The following example sets the VRRP reload latency on E0 to 10 seconds. When E0 is up, VRRP group 1 shall be reloaded in 10 seconds.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#vrrp delay minimum 10 reload 10
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
```

**Description**

### 3.9 vrrp description

Use this command to specify a descriptor for the VRRP.

Use the **no** form of this command to restore the default setting.

**vrrp [ ipv6 ] group description text**

**no vrrp [ ipv6 ] group description**

| Parameter Description | Parameter    | Description           |
|-----------------------|--------------|-----------------------|
|                       | <b>ipv6</b>  | Applies to IPv6 VRRP. |
|                       | <i>group</i> | VRRP group number     |
|                       | <i>text</i>  | VRRP group descriptor |

**Defaults** This function is disabled by default. Even if the VRRP function is enabled, no VRRP group descriptor is configured by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command will set the descriptor for the VRRP group to facilitate the identification of the VRRP group.

**Configuration Examples** The following example labels the VRRP group 1 on Ethernet interface E0 as Building A – Marketing and Administration.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 description "Building A -

|                  | <b>vrrp group ip ip-address [ secondary ]</b> | Enables the VRRP function and set the IP address for the virtual device |

**Platform** N/A

## Description

### 3.10 vrrp ip

Use this command to enable VRRP on the interface and specify the related virtual IP address.

Use the **no** form of this command to restore the default setting.

**vrrp group ip** *ipaddress* [ **secondary** ]

**no vrrp group ip** *ipaddress* [ **secondary** ]

| Parameter   | Parameter        | Description                                               |
|-------------|------------------|-----------------------------------------------------------|
| Description | <i>group</i>     | VRRP group number of the virtual device                   |
|             | <i>ipaddress</i> | IP address of the virtual device                          |
|             | <b>secondary</b> | Specifies the secondary IP address of the virtual device. |

**Defaults** This function is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** If the **secondary** parameter is not used, the IP address set here will become the master IP address of the virtual device.

**Configuration Examples** The following example enables the VRRP function on Ethernet interface 0. The VRRP group number is 1, primary IP address of the virtual device is 10.0.1.20 and secondary IP address is 10.0.2.20.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.2.1 255.255.255.0
secondary
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.2.20 secondary
```

| Related  | Command                                          | Description                      |
|----------|--------------------------------------------------|----------------------------------|
| Commands | <b>show vrrp</b> [ <b>brief</b>   <b>group</b> ] | Displays the VRRP configuration. |

**Platform** N/A

**Description**

### 3.11 vrrp ipv6

Use this command to enable IPv6 VRRP on the interface and specify the related virtual IPv6 address.

Use the **no** form of the command to restore the default setting.

**vrrp group ipv6** *ipv6-address*

**no vrrp group ip** *ipv6-address*

| Parameter   | Parameter           | Description                             |
|-------------|---------------------|-----------------------------------------|
| Description | <i>group</i>        | VRRP group number of the virtual device |
|             | <i>ipv6-address</i> | IPv6 address of the virtual device      |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** IPv6 VRRP and IPv4 VRRP share group numbers ranging from 1 to 255. One VRRP group number of an interface is applicable to both IPv4 VRRP and IPv6 VRRP at the same time. The first configured address should be the link's local address, which cannot be deleted until the other virtual addresses are deleted.

**Configuration Examples** The following example enables the IPv6 VRRP function on Ethernet interface FastEthernet 0/0 with VRRP group number 1 and virtual IPv6 address FE80::1 and 2001::1.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 enable
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 address 2001::2/64
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 FE80::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 2001::1
```

| Related Commands | Command                                 | Description                           |
|------------------|-----------------------------------------|---------------------------------------|
|                  | <b>show ipv6 vrrp [ brief   group ]</b> | Displays the IPv6 VRRP configuration. |

**Platform Description** N/A

### 3.12 vrrp preempt

Use this command to set the preemption mode of the VRRP group.

Use the **no** form of this command to restore the default setting.

**vrrp [ ipv6 ] group preempt [ delay seconds ]**

**no vrrp [ ipv6 ] group preempt [ delay ]**

| Parameter   | Parameter    | Description           |
|-------------|--------------|-----------------------|
| Description | <b>ipv6</b>  | Applies to IPv6 VRRP. |
|             | <i>group</i> | VRRP group number     |

|                             |                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------|
| <b>delay</b> <i>seconds</i> | (Optional) Specifies the delay before a device declares itself master. The default value is 0. |
|-----------------------------|------------------------------------------------------------------------------------------------|

**Defaults** This function is disabled by default. Once the VRRP function is enabled, the VRRP group will work in the preemption mode by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** If the VRRP group is working in the preemption mode, once a device finds its priority is higher than the priority of the master, it will become the master device of the VRRP group. If the VRRP group is not working in the preemption mode, even if a device finds its priority is higher than the master's priority, it will not become the master device of the VRRP group. In case the VRRP group is using the Ethernet interface IP address, the setting of the preemption mode does not make sense, because that VRRP group has the highest priority and thus automatically becomes the master device in the VRRP group.

**Configuration Examples** The following example enables IPv4 VRRP on interface GigabitEthernet 0/0. When VRRP group 1 finds its priority (200) is higher than that of the current master device, it will declare its preemption of master after a delay of 15 seconds.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 preempt delay 15
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 priority 200
```

The following example enables IPv4 VRRP on interface GigabitEthernet 0/0. When VRRP group 1 finds its priority (200) is higher than that of the current master device, it will declare its preemption of master after a delay of 15 seconds.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 enable
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 address 2001::2/64
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 FE80::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 2001::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 preempt delay 15
Ruijie(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 priority 200
```

**Related Commands**

| Command                                                    | Description                                                              |
|------------------------------------------------------------|--------------------------------------------------------------------------|
| <b>vrrp group ip</b> <i>ipaddress</i> [ <b>secondary</b> ] | Enables the VRRP function and set the IP address for the virtual device. |
| <b>vrrp group priority</b> <i>level</i>                    | Sets the VRRP group priority.                                            |

**Platform** N/A  
**Description**

### 3.13 vrrp priority

Use this command to specify the priority of the VRRP group.

Use the **no** form of this command to restore the default setting.

**vrrp [ ipv6 ] group priority level**

**no vrrp [ ipv6 ] group priority**

| Parameter          | Parameter    | Description                                    |
|--------------------|--------------|------------------------------------------------|
| <b>Description</b> | <b>ipv6</b>  | Specifies the priority of the IPv6 VRRP group. |
|                    | <i>group</i> | VRRP group number                              |
|                    | <i>level</i> | VRRP group priority                            |

**Defaults** This function is disabled by default. Once the VRRP function is enabled, the default priority of the VRRP group is 100.

**Command** Interface configuration mode  
**Mode**

**Usage Guide** This command is used to manually configure the VRRP router priority.

**Configuration** The following example sets the priority of IPv4 VRRP group 1 as 254.

**Examples**

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 priority 254
```

The following example sets the priority of IPv6 VRRP group 1 as 254.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 enable
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 address 2001::2/64
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 FE80::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 2001::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 priority 254
```

| Related         | Command                                      | Description                              |

|---------------------------------------------|---------------------------------------|
|                                             | address for the virtual device.       |
| <b>vrrp group preempt [ delay seconds ]</b> | Sets the VRRP in the preemption mode. |

**Platform** N/A

**Description**

### 3.14 vrrp timers advertise

Use this command to specify the interval for the master device to send the VRRP advertisement.

Use the **no** form of this command to restore the default setting.

**vrrp [ ipv6 ] group timers advertise { advertise-interval | csec centisecond-interval }**

**no vrrp [ ipv6 ] group timers advertise**

| Parameter          | Parameter                        | Description                                                                                                                                                                                                                                |
|--------------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <b>ipv6</b>                      | Applies to IPv6 VRRP.                                                                                                                                                                                                                      |
|                    | <i>group</i>                     | VRRP group number                                                                                                                                                                                                                          |
|                    | <i>advertise-interval</i>        | Sets the interval time in seconds between sending VRRP advertisement.                                                                                                                                                                      |
|                    | <b>csec centisecond-interval</b> | Sets the interval time in milliseconds between sending advertisement frames from the master VRRP router in the backup group. The range is from 50 to 99. This value is not set by default.<br>This parameter takes effect only for VRRPv3. |

**Defaults** This function is disabled by default. Once the VRRP function is enabled, the default advertisement interval of the master device is one second.

**Command** Interface configuration mode

**Mode**

**Usage Guide** If the current device becomes the master device in the VRRP group, it will notify its VRRP status, priority and other information by sending the VRRP advertisement in the set interval. Based on the RFC specification, the maximum advertisement interval of the IPv4/IPv6 VRRPv3 group is 40 seconds. The advertisement interval can be configured larger than 40 seconds, but the effective advertisement interval is 40 seconds.

**Configuration** The following example sets the IPv4 VRRP advertisement interval as 4 seconds.

**Examples**

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 4
```

The following example sets the IPv6 VRRP advertisement interval as 4 seconds.

```
Ruijie#configure terminal
```

```
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 enable
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 address 2001::2/64
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 FE80::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 2001::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 timers advertise 4
```

The following example sets the IPv4 VRRP advertisement interval as 50 centi-seconds.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise csec 50
```

The following example sets the IPv6 VRRP advertisement interval as 50 centi-seconds.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 enable
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 address 2001::2/64
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 FE80::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 2001::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 timers advertise csec 50
```

#### Related Commands

| Command                                                    | Description                                                              |
|------------------------------------------------------------|--------------------------------------------------------------------------|
| <b>vrrp group ip <i>ipaddress</i> [ <b>secondary</b> ]</b> | Enables the VRRP function and set the IP address for the virtual device. |
| <b>vrrp group timers learn</b>                             | Enables the timer learning function.                                     |

**Platform** N/A  
**Description**

### 3.15 vrrp timers learn

Use this command to enable the timer learning function.

Use the **no** form of this command to restore the default setting.

**vrrp [ *ipv6* ] group timers learn**

**no vrrp [ *ipv6* ] group timers learn**

#### Parameter Description

| Parameter    | Description           |
|--------------|-----------------------|
| <b>ipv6</b>  | Applies to IPv6 VRRP. |
| <b>group</b> | VRRP group number     |

**Defaults** This function is disabled by default. Even if the VRRP function is enabled, the timer learning function

is disabled by default.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Once the timer learning function is enabled, if the current device is a VRRP backup device, it will learn the VRRP advertisement interval from the VRRP advertisement of the master device, with which it calculates the master device's failure interval instead of the VRRP advertisement interval configured locally. This command may synchronize the VRRP advertisement timer with the master device.

**Configuration** The following example enables the timer learning function on the IPv4 VRRP group 1.

**Examples**

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 timers learn
```

The following example to enables the timer learning function on the IPv6 VRRP group 1.

```
vrrp ipv6 1 timers learn
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 enable
Ruijie(config-if-GigabitEthernet 0/0)#ipv6 address 2001::2/64
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 FE80::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 2001::1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 timers learn
```

**Platform** N/A

**Description**

### 3.16 vrrp track

Use these commands to enable the IPv4/IPv6 VRRP track in the interface configuration mode. Use the no form of these commands to restore the default setting.

```

vrrp group track { interface-type interface-number | bfd interface-type interface-number
ipv4-address } [ priority ]
vrrp ipv6 group track interface-type interface-number [ priority ]
no vrrp [ ipv6 ] group track interface-type interface-number

```

Use these commands to enable VRRP IPv4/IPv6 address track. Use the **no** form of these commands to restore the default setting.

```

vrrp group track ipv4-address [ interval interval-value ] [ timeout timeout-value ] [ retry retry-value ]
[ priority ]
vrrp ipv6 group track { ipv6-global-address | ipv6-linklocal-address interface-type interface-number }
[ interval interval-value ] [ timeout timeout-value ] [ retry retry-value ] [ priority ]
no vrrp group track ipv4-address
no vrrp ipv6 group track { ipv6-global-address | ipv6-linklocal-address interface-type interface-
number }

```

Use this command to disable the specified neighbor IP address track via BFD.

```

no vrrp group track bfd interface-type interface-number ipv4-address

```

| Parameter                     | Parameter                                                                | Description                                                                                                                                            |
|-------------------------------|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description                   | <i>group</i>                                                             | VRRP group number                                                                                                                                      |
|                               | <i>interface-type</i><br><i>interface-number</i>                         | Type of monitored interface                                                                                                                            |
|                               | <b>bfd</b> <i>interface-type</i><br><i>interface-number ipv4-address</i> | Enables the specified neighbor IP address track via BFD.                                                                                               |
|                               | <i>priority</i>                                                          | VRRP priority change range when the interface or ip address reachability status changes. If this parameter is not selected, the default value is 10.   |
|                               | <b>ipv6</b>                                                              | Applies to IPv6 VRRP.                                                                                                                                  |
|                               | <i>ipv4-address</i>                                                      | Monitored IPv4 address. With BFD configured, it refers to the neighbor IP address.                                                                     |
|                               | <b>interval</b> <i>interval-value</i>                                    | The interval of time to probe whether the monitored ip address is reachable or not. If this parameter is not selected, the default value is 3 seconds. |
|                               | <b>timeout</b> <i>timeout-value</i>                                      | The timeout time of the unreachable monitored ip address. If this parameter is not selected, the default value is 1 seconds.                           |
|                               | <b>retry</b> <i>retry-value</i>                                          | Track retries. If the value is reached, the link is thought unreachable. If this parameter is not configured, the default value is 3.                  |
|                               | <i>ipv6-global-address</i>                                               | Global unicast IPv6 address                                                                                                                            |
| <i>ipv6-linklocal-address</i> | Local link IPv6 address                                                  |                                                                                                                                                        |

#### Defaults

This function is disabled by default. Even if the VRRP function is enabled, no interface or IP address is specified.

**Command** Interface configuration mode  
**Mode**

**Usage Guide**

- i This command can be used to monitor the outlet links. Note that layer-3 routable logical interfaces can be monitored (such as Routed Port, SVI, Loopback and Tunnel).
- i If a host is monitored, specify the IPv4 address for the IPv4 VRRP router or the IPv6 address for the IPv6 VRRP router.
- i If the host IP address is link-local, an interface must be specified.
- i If a VRRP router owns the IP address of the physical interface, the priority is 255. Keep the priority when the monitored IP address or interface is set.

**Configuration Examples** The following example enables the VRRP group 1 to monitor the routed port Fa1/1. If the Fa1/1 link is disconnected, the priority of the VRRP group decreases by 30. When the Fa1/1 link recovers, the priority of VRRP group 1 is restored.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 priority 254
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 track GigabitEthernet 1/1 30
```

The following example sets the VRRP to track the specified neighbor IP address 192.168.1.3 through BFD:

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface FastEthernet 0/1
Ruijie(config-if)#no switchport //used on the switch.
Ruijie(config-if)#ip address 192.168.1.1 255.255.255.0
Ruijie(config-if)#bfd interval 50 min_rx 50 multiplier 3
Ruijie(config)#interface FastEthernet 0/2
Ruijie(config-if)#no switchport //used on the switch
Ruijie(config-if)#ip address 192.168.201.17 255.255.255.0
Ruijie(config-if)#vrrp 1 priority 120
Ruijie(config-if)#vrrp 1 ip 192.168.201.1
Ruijie(config-if)#vrrp 1 track bfd FastEthernet 0/1 192.168.1.3 30
Ruijie(config-if)#end
```

|----------------------------------------------------|------------------------------------------|
| <code>vrrp group ip ipaddress [ secondary ]</code> | Enables the VRRP function and set the IP |

|                                  |                                 |
|----------------------------------|---------------------------------|
|                                  | address for the virtual device. |
| <b>vrrp group priority level</b> | Sets the VRRP group priority.   |

**Platform** N/A

**Description**

### 3.17 vrrp version

Use this command to configure the version of sending the IPv4 VRRP multicast packets.

For the IPv4 VRRP, there are two versions: VRRPv2 and VRRPv3.

Use the **no** form of this command to restore the default setting.

**vrrp group version { 2 | 3 }**

**no vrrp group version**

| Parameter          | Parameter | Description                                  |
|--------------------|-----------|----------------------------------------------|
| <b>Description</b> | <b>2</b>  | Uses the VRRPv2 version to send the packets. |
|                    | <b>3</b>  | Uses the VRRPv3 version to send the packets. |

**Defaults** The default is VRRPv2.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Considering the compatibility of VRRPv2 and VRRPv3 for the IPv4 VRRP, you can choose the version of VRRP packets based on the actual network environment. VRRPv2 is based on RFC3768 and VRRPv3 is based on RFC 5798.

 This command is applicable to IPv4 VRRP only.

**Configuration Examples** The following example configures the version of sending the IPv4 VRRP packets on the interface gi0/0.

```
Ruijie#configure terminal
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#no switchport //used on the switch.
Ruijie(config-if-GigabitEthernet 0/0)#ip address 10.0.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 10.0.1.20
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 version 3
```

**Related Commands**

| Command                                      | Description                                                              |
|----------------------------------------------|--------------------------------------------------------------------------|
| <b>vrrp group ip ipaddress [ secondary ]</b> | Enables the VRRP function and set the IP address for the virtual device. |
| <b>vrrp group timers advertise interval</b>  | Sets the interval of sending the VRRP advertisement.                     |

**Platform** N/A

**Description**

### 3.18 vrrp detection-vlan

Use this command to enable IPv4 VRRP packets to be sent to only the first or a specified Sub VLAN in a Super VLAN interface.

Use the **no** form of this command to enable IPv4 VRRP packets to be sent to all the Sub VLANs in a Super VLAN interface.

**vrrp detection-vlan** {**first-subvlan** | *subvlan-id*}

**no vrrp detection-vlan**

| Parameter          | Parameter            | Description                                                                      |
|--------------------|----------------------|----------------------------------------------------------------------------------|
| <b>Description</b> | <b>first-subvlan</b> | IPv4 VRRP packets are sent to only the first Sub VLAN in a Super VLAN interface. |
|                    | <i>subvlan-id</i>    | IPv4 VRRP packets are sent to a specified Sub VLAN in a Super VLAN interface.    |

**Defaults** By default, IPv4 VRRP packets are sent to only the first Sub VLAN in a Super VLAN interface.

**Command** Interface configuration mode

**Mode**

**Usage Guide** Use this command to configure the mode in which IPv4 VRRP packets are sent to a Super VLAN interface. There are three modes in which IPv4 VRRP packets are sent to a Super VLAN interface: to only the first Sub VLAN, to a specified Sub VLAN, or all Sub VLANs.

 This command is configured on a VLAN interface and applies only to Super VLAN interfaces.

**Configuration** The following example enables IPv4 VRRP packets to be sent to all Sub VLANs in Super VLAN 3.

**Examples**

```
Ruijie#configure terminal
Ruijie(config)# vlan 3
Ruijie(config-vlan)# supervlan
Ruijie(config-vlan)# subvlan 5-10
Ruijie(config-vlan)#exit
Ruijie(config)#interface vlan 3
Ruijie(config-if)# no vrrp detection-vlan
```

## 4 VRRP Plus Commands

### 4.1 show vrrp balance

Use this command to display the VRRP Plus brief or details.

**show vrrp balance** [ **brief** | *group* ]

| Parameter Description | Parameter    | Description                                |
|-----------------------|--------------|--------------------------------------------|
|                       | <b>brief</b> | (Optional) Displays the VRRP Plus brief.   |
|                       | <i>group</i> | (Optional) Displays the VRRP Plus details. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** If no optional parameter is used, the details of all VRRP Plus group are displayed.

**Configuration Examples** The following example displays the details of all VRRP Plus groups.

```
Ruijie#show vrrp balance
VLAN 1 - Group 1
  State is BVG
  Virtual IP address is 192.168.1.54
  Hello time 1 sec, hold time 3 sec
  Load balancing: host-dependent
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 90 (configured 100), thresholds: lower 1, upper 100
  Track object 1, state: down, decrement weight: 10
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0101
    Owner ID is 00d0.f822.33ab
  Forwarder 2
    MAC address:
      001a.a916.0201
  Owner ID is 00d0.f822.8800
Ruijie#show ipv6 vrrp balance
VLAN 2 - Group 1
  State is BVG
  Virtual IPv6 address is as follows:
    FE80::8
```

```

2000::8
Hello time 2 sec, hold time 6 sec
Load balancing: weighted
Redirect time 300 sec, forwarder time-out 14400 sec
Weighting 100 (configured 100), thresholds: lower 1, upper 100
There are 2 forwarders
Forwarder 1 (local)
  MAC address:
    0000.5e00.0201
  Owner ID is 00d0.f822.33f5
  Preemption disabled (BVG cannot be preempted)
Forwarder 2
  MAC address:
    1414.4b72.7701
  Owner ID is 00d0.f822.33b9
Preemption enabled

```

The following example shows the brief of the VRRP Plus group.

```

Ruijie# show vrrp balance brief
Interface Grp  State      Group Addr      MAC addr
VLAN 1      1   BVG       192.168.1.1    0000.5e00.0101

```

|------------------------------------------------------------------------------|-------------------------------------------------------------------|
| <b>vrrp group balance</b>                                                    | Enables the VRRP Plus function.                                   |
| <b>vrrp group load-balancing { host-dependent   round-robin   weighted }</b> | Sets the load balancing policy of the VRRP Plus.                  |
| <b>show vrrp balance interface type number [ brief ]</b>                     | Displays the VRRP Plus running status of the specified interface. |

**Platform** N/A

**Description**

## 4.2 show vrrp balance interface

Use this command to display the actions of the VRRP Plus group on the specified interface.

**show vrrp balance interface type number [ brief ]**

#### Parameter Description

| Parameter                    | Description                                |
|------------------------------|--------------------------------------------|
| <b>interface type number</b> | Specifies the interface type and number.   |
| <b>brief</b>                 | (Optional) Displays the brief information. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode/Global configuration mode/Interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the actions of the VRRP Plus on FastEthernet 0/0.

```

Ruijie# show vrrp balance interface FastEthernet 0/0
FastEthernet 0/0 - Group 1
  State is BVG
  Virtual IP address is 192.168.1.54
  Hello time 1 sec, hold time 3 sec
  Load balancing: host-dependent
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 90 (configured 100), thresholds: lower 1, upper 100
    Track object 1, state: down, decrement weight: 10
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0101
    Owner ID is 00d0.f822.33ab
  Forwarder 2
    MAC address:
      001a.a916.0201
    Owner ID is 00d0.f822.8800

```

| <b>vrrp group balance</b>                                                    | Enables the VRRP Plus function.                                   |
| <b>vrrp group load-balancing { host-dependent   round-robin   weighted }</b> | Sets the load balancing policy of the VRRP Plus.                  |
| <b>show vrrp balance interface type number [ brief ]</b>                     | Displays the VRRP Plus running status of the specified interface. |

**Platform** N/A

**Description**

### 4.3 vrrp balance

Use this command to enable the VRRP Plus function.

Use the **no** form of this command to disable this function.

**vrrp group balance**

**no vrrp group balance**

| Parameter<br>Description | Parameter | Description  |
|--------------------------|-----------|--------------|
|                          |           | <i>group</i> |

**Defaults** VRRP Plus is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** To enable VRRP Plus, you must configure the VRRP group first.

**Configuration Examples** The following example enables the VRRP Plus function on the Layer 3 interface GigabitEthernet0/0.

```
Ruijie#config
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.1.1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 balance
```

| Related<br>Commands | Command                            | Description                                                       |
|---------------------|------------------------------------|-------------------------------------------------------------------|
|                     | <b>vrrp load-balancing</b>         | Sets the load balancing policy of the VRRP Plus.                  |
|                     | <b>show vrrp balance</b>           | Displays the VRRP Plus running status.                            |
|                     | <b>show vrrp balance interface</b> | Displays the VRRP Plus running status of the specified interface. |

**Platform Description** N/A

## 4.4 vrrp forwarder preempt

Use this command to enable the forwarding preemption on the VRRP Plus backup group.

Use the **no** form of this command to disable this function.

**vrrp *group* forwarder preempt**

**no vrrp *group* forwarder preempt**

| Parameter<br>Description | Parameter | Description  |
|--------------------------|-----------|--------------|
|                          |           | <i>group</i> |

**Defaults** By default, forwarding preemption is enabled.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables the forwarding preemption function of the VRRP Plus backup group on the Layer3 interface GigabitEthernet 0/0.

```
Ruijie#config
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.1.1
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 balance
Ruijie(config-if-GigabitEthernet 0/0)#vrrp 1 forwarder preempt
```

**Related Commands**

|----------------------------------------------------------|-------------------------------------------------------------------|
| <b>vrrp group balance</b>                                | Enables the VRRP Plus function.                                   |
| <b>show vrrp balance [ brief   group ]</b>               | Displays the VRRP Plus running status.                            |
| <b>show vrrp balance interface type number [ brief ]</b> | Displays the VRRP Plus running status of the specified interface. |

**Platform** N/A

**Description**

## 4.5 vrrp load-balancing

Use this command to set the VRRP Plus load balancing policy.

Use the **no** form of this command to restore the default setting.

**Vrrp group load-balancing { host-dependent | round-robin | weighted }**

**no vrrp group load-balancing { host-dependent | round-robin | weighted }**

**Parameter Description**

| Parameter             | Description                                                                                                                                           |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>group</i>          | Specifies the VRRP group ID.                                                                                                                          |
| <b>host-dependent</b> | Sets the host-dependent load balancing policy, so as to use the different virtual MACs to reply the host's ARP request based on different hosts.      |
| <b>round-robin</b>    | Sets the round-robin balancing policy, so as to use the different virtual MACs to reply the host's ARP request in turn, which is the default setting. |
| <b>weighted</b>       | Sets the weight balancing policy, so as to perform the ARP reply based on the device weight of the backup group.                                      |

**Defaults** The default is round-robin.

**Command Mode** Interface configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the load balancing policy of the VRRP Plus group1 on Layer 3 interface GigabitEthernet0/0 as host-dependent.

```
Ruijie# config t
Ruijie(config)# interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 ip 192.168.1.1
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 balance
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 load-balancing host-dependent
```

**Related Commands**

|----------------------------------------------------------|------------------------------------------------------------------|
| <b>vrrp group balance</b>                                | Enables the VRRP Plus function.                                  |
| <b>show vrrp balance [ brief   group ]</b>               | Displays the VRRP Plus running status.                           |
| <b>show vrrp balance interface type number [ brief ]</b> | Displays the VRRP Plus running status o the specified interface. |

**Platform** N/A

**Description**

## 4.6 vrrp timers redirect

Use this command to set the redirection interval and timeout of the proxy virtual MAC address for the VRRP Plus backup group.

Use the **no** form of this command to restore the default value.

**vrrp group timers redirect redirect timeout**

**no vrrp group timers redirect**

**Parameter Description**

| Parameter       | Description                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------|
| <i>group</i>    | VRRP Plus backup group ID, in the range of 1 to 255.                                               |
| <i>redirect</i> | The redirection time, 300 seconds (namely 5 minutes) by default, in the range of 0 to 3,600.       |
| <i>timeout</i>  | The timeout, 14,400 seconds (namely 4 hours) by default, in the range of (redirect+600) to 64,800. |

**Defaults** The default redirection interval is 300 seconds and redirection timeout is 14,400 seconds.

**Command Mode** Interface configuration mode

**Usage Guide** The VRRP Plus function should be enabled before setting the redirection interval and timeout of the

proxy virtual MAC address for the VRRP Plus backup group.

**Configuration Examples** The following example sets the redirection interval and timeout of the proxy virtual MAC address for the VRRP Plus backup group.

```
Ruijie#config
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 ip 192.168.1.1
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 balance
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 timers redirect 300 6000
```

**Related Commands**

| <b>vrrp group balance</b>                                | Enables the VRRP Plus function.                                  |
| <b>show vrrp balance [ brief   group ]</b>               | Displays the VRRP Plus running status.                           |
| <b>show vrrp balance interface type number [ brief ]</b> | Displays the VRRP Plus running status o the specified interface. |

**Platform** N/A

**Description**

## 4.7 vrrp weighting

Use this command to set the weight and threshold of the VRPP Plus backup group.

Use the **no** form of this command to restore the default setting.

**vrrp group weighting maximum [ lower lower ] [ upper upper ]**

**no vrrp group weighting**

**Parameter Description**

| Parameter      | Description                                                     |
|----------------|-----------------------------------------------------------------|
| <i>group</i>   | VRRP Plus backup group ID, in the range of 1 to 255.            |
| <i>maximum</i> | Weight, 100 by default, in the range of 2 to 254.               |
| <i>lower</i>   | Weight lower, 1 by default, in the range of 1 to (maximum-1)    |
| <i>upper</i>   | Weight upper, 100 by default, in the range of lower to maximum. |

**Defaults** VRRP Plus backup group weight: 100

Weight lower: 1

Weight upper: 100

**Command Mode** Interface configuration mode

**Usage Guide** The VRRP Plus function should be enabled before setting the weight and threshold of the VRRP Plus backup group

**Configuration** The following example sets the weight and threshold of the VRRP Plus group1.

**Examples**

```
Ruijie#config t
Ruijie(config)#interface GigabitEthernet 0/0
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 ip 192.168.1.1
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 balance
Ruijie(config-if-GigabitEthernet 0/0)# vrrp 1 weighting 50 lower 30 upper 50
```

**Description**

## 5 BFD Commands

### 5.1 bfd

Use this command to set the BFD session parameters.

Use the **no** form of this command to remove the setting.

**bfd interval** *milliseconds* **min\_rx** *milliseconds* **multiplier** *multiplier-value*

**no bfd interval**

| Parameter Description | Parameter                                 | Description                                                                                                                                        |
|-----------------------|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>interval</b> <i>milliseconds</i>       | Interval of sending the BFD control messages to the BFD session neighbor.<br><i>milliseconds</i> : The range is from 50 to 10,000 ms.              |
|                       | <b>min_rx</b> <i>milliseconds</i>         | Expected interval of receiving the BFD control messages from the BFD session neighbor.<br><i>milliseconds</i> : The range is from 50 to 10,000 ms. |
|                       | <b>multiplier</b> <i>multiplier-value</i> | Count of BFD control message not received from the peer in the configured interval.<br><i>multiplier-value</i> : The range is from 3 to 50.        |

**Defaults** No BFD session parameter is configured by default.

**Command Mode** Interface configuration mode for single-hop sessions, BFD template mode for multi-hop sessions

**Usage Guide** The express forwarding must be enabled before enabling BFD on the routers. BFD session parameters should be consistent on peers, so that associated protocols will take effect at the same time. If not, one-way forwarding will occur. Set the parameters based on interface bandwidth. If **interval** and **min\_rx** are too short, BFD sessions may occupy much bandwidth and influence data transmission. If multi-hop session parameters need to be configured using a template, configure the template first and then configure BFD multi-hop session parameters.

**Configuration Examples** The following example configures the BFD session parameters on routed port FastEthernet 0/2.

```
Ruijie(config)# interface fastEthernet 0/2
Ruijie(config)# no switchport
Ruijie(config-if)# bfd interval 100 min_rx 100 multiplier 3
```

**Description**

## 5.2 bfd bind peer-ip

Use this command to create a BFD session to correlate with an interface.

Use the **no** form of this command to remove this setting.

**bfd bind peer-ip** *ip-address* [ **source-ip** *ip-address* ] **process-pst**

**no bfd bind peer-ip** *ip-address*

| Parameter Description | Parameter                          | Description                                                                                                                                                                         |
|-----------------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <b>peer-ip</b> <i>ip-address</i>   | The peer IP address to be detected, which must be directly connected to the Layer 3 interface.                                                                                      |
|                       | <b>source-ip</b> <i>ip-address</i> | Source IP address for sending the BFD packets, which avoids the packets dropped by the URPF in case that this function is used with other functions such the URPF at the same time. |
|                       | <b>process-pst</b>                 | Correlates BFD for the Layer3 interface.                                                                                                                                            |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** Note that this command must be configured a Layer 3 interface and the peer IP address detected must be the address directly-connected to the interface.

**Configuration Examples** The following example detects the peer 1.1.1.2 through BFD on the routed port to generate the BFD status of the interface.

```
Ruijie(config)# interface gigabitEthernet 0/2
Ruijie(config-if -GigabitEthernet 0/2)#no sw
Ruijie(config-if -GigabitEthernet 0/2)#ip address 1.1.1.1 255.255.255.0
Ruijie(config-if -GigabitEthernet 0/2)#bfd bind peer-ip 1.1.1.2 source-ip
1.1.1.1 process-pst
```

**Description**

## 5.3 bfd cpp

Use this command to enable the BFD protection policy.

Use the **no** form of this command to disable this function.

**bfd cpp**

**no bfd cpp**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command** Global configuration mode

**Mode**

**Usage Guide** BFD protocol is so sensitive that if the device with BFD function enabled suffers from attack (for example, a large amount of Ping packets attack the device), which lead to the BFD session turbulence, the device can be protected by enabling the BFD protection policy. However, if the BFD function and the BFD protection policy are enabled at the same time, the loss of BFD packets on the attacked device occurs when the packets sent from the last-hop device go through this device, influencing the BFD session establishment between the last-hop device and other devices. This function is valid only for the switches.

**Configuration** The following example enables the BFD protection policy.

**Examples** Ruijie(config)# **bfd cpp**

| Related Commands | Command | Description |
|------------------|---------|-------------|

**Description**

## 5.4 bfd echo

Use this command to enable echo mode.

Use the **no** form of this command to disable echo mode.

**bfd echo**

**no bfd echo**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|     |     |
|-----|-----|
| N/A | N/A |
|-----|-----|

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** By default, with BFD session parameter configured, the system enables the echo mode automatically. The minimum sending and receiving interval for the echo packets are the values of the configured **interval** *milliseconds* and **min\_rx** *milliseconds*.  
This command cannot be configured on the AP port.  
Before enabling BFD echo mode, it is necessary to use the **no ip redirects** command to disable the ICMP redirection messages sending on the neighbor device of the BFD session, use the **no ip deny land** to disable the DDOS (Land-based attack prevention) function.  
With both ends of the BFD session enabled, the echo mode takes effect.  
In the process that the forwarding plane of the peer device returns echo packets transmitted by the local end to the local end, the echo packets may be lost due to congestion of the peer device, causing a session detection failure. In this case, configure Quality of Service (QoS) policies to ensure that echo packets are processed preferentially or disable the echo function.  
The echo detection function of BFD does not support multi-hop detection. Ensure that the echo function is disabled when configuring multi-hops.

**Configuration Examples** The following example enables the echo mode on the routed port FastEthernet 0/2:

```
Ruijie(config)# interface fastEthernet 0/2
Ruijie(config)# no switchport
Ruijie(config-if)# bfd echo
```

| <b>Parameter Description</b> | <b>Parameter</b>                                                                                                                                                                                                                                                                                                                                                                                                        | <b>Description</b>                                                                                  |
|                              | <i>milliseconds</i>                                                                                                                                                                                                                                                                                                                                                                                                     | (Optional) Sets the BFD up-dampening time. The range is from 0 to 300,000. The unit is millisecond. |
| <b>Defaults</b>              | The default is 0 millisecond, which means that the notification is sent to the related application once the session state is UP.                                                                                                                                                                                                                                                                                        |                                                                                                     |
| <b>Command Mode</b>          | Interface configuration mode for single-hop sessions, BFD template mode for multi-hop sessions                                                                                                                                                                                                                                                                                                                          |                                                                                                     |
| <b>Usage Guide</b>           | <p>This function needs to be enabled only when the link is instable.</p> <p>If a BFD session does not frequently switch over between Down and Up, the enabling of BFD flapping dampening will delay notifying an associated application of BFD Up.</p> <p>If multi-hop session parameters need to be configured using a template, configure the template first and then configure BFD multi-hop session parameters.</p> |                                                                                                     |

**Configuration** The following example sets the BFD up-dampening time to 60,000 milliseconds.

**Examples** Ruijie(config)# bfd up-dampening 60000

**Related  
Commands**

| Command    | Description                           |
|------------|---------------------------------------|
| <b>bfd</b> | Configures the BFD session parameter. |

**Platform** N/A

**Description**

## 5.7 show bfd neighbors

Use this command to display the BFD session parameters.

**show bfd neighbors** [ vrf *vrf-name* ] [ client { ap | bgp | isis | ospf | ospfv3 | rip | vrrp | static-route | pbr | vrrp-balance | pst } ] [ ipv4 *ip-address* | ipv6 *ip-address* ] [ details ]

**Parameter  
Description**

| Parameter                     | Description                                                                 |
|-------------------------------|-----------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i>    | (Optional) sets the neighbor VRF name.                                      |
| <b>client</b>                 | (Optional) specifies the routing protocol.                                  |
| <b>ap</b>                     | Displays the BFD session configuration for Layer 3 aggregate ports.         |
| <b>bgp</b>                    | Displays the BFD session configuration for BGP.                             |
| <b>isis</b>                   | Displays the BFD session configuration for ISIS.                            |
| <b>ospf</b>                   | Displays the BFD session configuration for OSPF.                            |
| <b>ospfv3</b>                 | Displays the BFD session configuration for OSPFv3.                          |
| <b>rip</b>                    | Displays the BFD session configuration for RIP.                             |
| <b>vrrp</b>                   | Displays the BFD session configuration for VRRP.                            |
| <b>static-route</b>           | Displays the BFD session configuration for the static route.                |
| <b>pbr</b>                    | Displays the BFD session configuration for PBR.                             |
| <b>vrrp-balance</b>           | Displays the BFD session configuration for the VRRP.                        |
| <b>pst</b>                    | Displays the BFD session configuration and the Layer3 interface status.     |
| <b>ipv4</b> <i>ip-address</i> | (Optional) Displays the session information of the specified IPv4 neighbor. |
| <b>ipv6</b> <i>ip-address</i> | (Optional) Displays the session information of the specified IPv6 neighbor. |
| <b>details</b>                | (Optional) Displays the configurations in detail.                           |

**Defaults** N/A

**Command** Privileged EXEC mode

**Mode**

**Usage Guide** In the information displayed by the **show bfd neighbors** command, the OurAddr field means the source address of the session. The "-" is displayed if the source address is not specified, and it occurs in the BFD session for the LSP backward IP correlation.

**Configuration** The following example displays the BFD session configuration.

**Examples**

```
Ruijie# sh bfd neighbors
IPV4 sessions: 1, UP: 1
IPV6 sessions: 0, UP: 0
OurAddr      NeighAddr    LD/RD      RH Holddown(mult) State Int
192.168.24.2 192.168.24.1 8192/8192  Up  0(3)      Up GigabitEthernet 0/1
```

The following example displays the BFD session configuration in detail.

```
Ruijie#sh bfd neighbors
IPV4 sessions: 1, UP: 1
IPV6 sessions: 0, UP: 0
OurAddr      NeighAddr    LD/RD      RH/RS    Holddown(mult) State Int
192.168.24.2 192.168.24.1 8192/8192  Up       0(3 )      Up
GigabitEthernet 0/1
Session state is Up and using echo function with 50 ms interval.
Local Diag:  0,      Demand mode:  0,      Poll bit:  0
MinTxInt: 3000000,      MinRxInt: 3000000,      Multiplier:  3
Received MinRxInt 3000000, Multiplier:  3
Holddown (hits): 9000(0), Hello (hits): 3000(36)
Rx Count: 127, Rx Interval (ms) min/max/avg: 40/999/999
Tx Count: 135, Tx Interval (ms) min/max/avg: 1000/1000/999
Registered protocols: VRRP
Uptime: 0:01:19
Last packet:
Version      :      1          - Diagnostic    : 0
State bit    :      Up        - Demand bit    : 0
Poll bit     :      0          - Final bit     : 0
Multiplier  :      3          - Length        : 24
My Discr     :      8192       - Your Discr    : 8192
Min tx interval : 3000000      - Min rx interval: 3000000
Min Echo interval: 50000
```

The following example displays the BFD session configuration for Layer 3 aggregate ports.

```
Ruijie#show bfd neighbors client ap
IPV4 sessions: 1, UP: 0
IPV6 sessions: 0, UP: 0
OurAddr      NeighAddr    LD/RD      RH/RS    Holddown(mult) State Int
192.168.23.1 192.168.23.2 8192/0     Admin    0(3 )      Down
GigabitEthernet 0/2 (AP 1)
```

## 6 IP Event Dampening Commands

### 6.1 dampening

Use this command to enable the IP event dampening function on the interface. Use the **no** or **default** form of this command to disable this function.

**dampening** [ *half-life-period* [ *reuse-threshold* *suppress-threshold* *max-suppress* [ **restart** [ *restart-penalty* ] ] ] ] ]

**no dampening**

**default dampening**

| Parameter Description | Parameter                 | Description                                                                                                                             |
|-----------------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>half-life-period</i>   | Configures the half-life period of suppression penalty. The range is from 1 to 30. The unit is seconds. The default value is 5 seconds. |
|                       | <i>reuse-threshold</i>    | Configures the penalty threshold to unsuppress the interface. The range is from 1 to 20,000. The default value is 1,000.                |
|                       | <i>suppress-threshold</i> | Configures the penalty threshold to suppress the interface. The range is from 1 to 20,000. The default value is 2,000.                  |
|                       | <i>max-suppress</i>       | Configures the maximum suppress time. The range is from 1 to 255. The default value is 4 times of the <i>half-life-period</i> .         |
|                       | <b>restart-penalty</b>    | Configures the initial penalty value on the interface. The range is from 1 to 20,000. The default value is 2,000.                       |

**Defaults** IP event dampening is disabled by default.

**Command mode** Interface configuration mode.

**Usage Guide** This function will influence the modules of the directly-connected/host route, static route, dynamic route and VRRP. If one interface meets the configuration condition of this command, which is in the suppression status, the above influenced modules consider the status of this interface as DOWN, so as to delete the corresponding route and not transceive the data packets on this interface. Re-configuring the dampening command on the interface that has been configured this command makes all dampening information on this interface cleared. However, the interface flapping times will be remained unless use the clear counters command to clear the statistical information of the interface.

**Configuration** The following example configures the IP event dampening function.

**Examples**

```
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# no switchport
Ruijie(config-if-GigabitEthernet 0/1)# dampening 30 1500 10000 100
```

| Related<br>Commands | Command                         | Description                                         |
|---------------------|---------------------------------|-----------------------------------------------------|
|                     | <b>clear counters</b>           | Clears the interface counters.                      |
|                     | <b>show dampening interface</b> | Displays the statistics of the dampening interface. |
|                     | <b>show interface dampening</b> | Displays details of the dampening interface.        |

**Platform** When a Layer-3 port on a switch is converted to a Layer-2 port (for example, from a routed port to a switch port), the IP Event Dampening configuration on the port will be deleted.

**Description**

## 6.2 show dampening interface

Use this command to show the statistics of the dampening interface.

**show dampening interface**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          | N/A       | N/A         |

**Defaults** N/A

**Command mode** Privileged EXEC mode/ global configuration mode/ interface configuration mode

**Usage Guide** N/A

**Configuration** The following example displays the statistics of the dampening interface.

**Examples**

```
Ruijie# show dampening interface
3 interfaces are configured with dampening.
No interface is being suppressed.
```

| Related<br>Commands | Command                         | Description                                               |
|---------------------|---------------------------------|-----------------------------------------------------------|
|                     | <b>dampening</b>                | Enables the IP event dampening function on the interface. |
|                     | <b>clear counters</b>           | Clears the interface counters.                            |
|                     | <b>show interface dampening</b> | Displays details of IP event dampening configuration.     |

**Platform** N/A

**Description**

## 6.3 show interface dampening

Use this command to display the details of IP event dampening configuration.

**show interface** [ *interface-Id* ] **dampening**

| Parameter Description | Parameter           | Description    |
|-----------------------|---------------------|----------------|
|                       | <i>interface-id</i> | Interface name |

**Defaults** N/A

**Command mode** Privileged EXEC mode/ global configuration mode/ interface configuration mode

**Usage Guide** If the interface-id is specified, only the dampening information of this specified interface is displayed.

**Configuration** The following example shows the details of IP event dampening configuration.

```
Ruijie# show interface dampening Ethernet1/0
Flaps Penalty Supp ReuseTm HalfL ReuseV SuppV MaxSTm MaxP Restart
0 0 FALSE 0 5 1000 2000 20 16000 0
```

| Domain  | Description                                   |
|---------|-----------------------------------------------|
| Flaps   | Interface flapping times.                     |
| Penalty | The current penalty value on the interface.   |
| Supp    | Suppressed or not.                            |
| ReuseTm | Time to unsuppress the interface, in seconds. |
| HalfL   | Half-life period, in seconds.                 |
| ReuseV  | Unsuppressed threshold.                       |
| SuppV   | Start suppression threshold.                  |
| MaxSTm  | Maximum suppression time.                     |
| MaxP    | Maximum penalty value.                        |
| Restart | The initial penalty value on the interface.   |

| Related Commands | Command                         | Description                                     |
|------------------|---------------------------------|-------------------------------------------------|
|                  | <b>dampening</b>                | Enables the IP event dampening function.        |
|                  | <b>clear counters</b>           | Clears the interface counters.                  |
|                  | <b>show dampening interface</b> | Displays statistics of the dampening interface. |

**Platform Description** N/A

## 7 VSU Commands

### 7.1 dad relay enable

Use this command to enable the Dual-Active Detection (DAD) relay function.

Use the **no** form of this command to restore the default setting.

**dad relay enable**

**no dad relay enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is disabled by default.

**Command Mode** Interface configuration mode

**Usage Guide** This command is only supported on the aggregate port (AP).

**Configuration Examples** The following example enables the AP-based DAD relay function.

```
Ruijie(config)#interface aggregateport 1
Ruijie(config-if-AggregatePort 1)#dad relay enable
```

The following example disables the AP-based DAD relay function.

```
Ruijie(config)#interface aggregateport 1
Ruijie(config-if-AggregatePort 1)#no dad relay enable
Ruijie(config-if-AggregatePort 1)#exit
```

| Related Commands | Command                                | Description                                                                         |
|------------------|----------------------------------------|-------------------------------------------------------------------------------------|
|                  | <b>dual-active detection</b>           | Configures DAD.                                                                     |
|                  | <b>dual-active pair interface</b>      | Configures a pair of Bidirectional Forwarding Detection (BFD)-based DAD interfaces. |
|                  | <b>dual-active exclude interface</b>   | Configures an exclude interface of DAD.                                             |
|                  | <b>show switch virtual dual-active</b> | Displays the configuration and status of DAD.                                       |

**Platform** N/A

**Description**

### 7.2 dual-active bfd interface

Use this command to configure a BFD port.

Use the **no** form of this command to remove the setting.

**dual-active bfd interface** *interface-name*

**no dual-active bfd interface** *interface-name*

| Parameter   | Parameter             | Description    |
|-------------|-----------------------|----------------|
| Description | <i>interface-name</i> | Interface name |

**Defaults** N/A

**Command Mode** config-vs-domain configuration mode

**Usage Guide** The BFD port must be a routing port on the peer end.

**Configuration** The following examples configures interface Gi 1/1/1 as a BFD port.

**Examples**

```
Ruijie(config)# interface GigabitEthernet 1/1/1
Ruijie(config-if- GigabitEthernet 1/1/1)# no switchport
Ruijie(config)# interface GigabitEthernet 2/1/1
Ruijie(config-if- GigabitEthernet 2/1/1)# no switchport
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# dual-active bfd interface GigabitEthernet 1/1/1
Ruijie(config-vs-domain)# dual-active bfd interface GigabitEthernet 2/1/1
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform** N/A

**Description**

## 7.3 dual-active detection

Use this command to enable DAD.

Use the **no** form of this command to restore the default setting.

**dual-active detection { bfd | aggregateport }**

**no dual-active detection { bfd | aggregateport }**

| Parameter   | Parameter            | Description   |
|-------------|----------------------|---------------|
| Description | <b>bfd</b>           | BFD-based DAD |
|             | <b>aggregateport</b> | AP-based DAD  |

**Defaults** This function is disabled by default.

**Command Mode** config-vs-domain configuration mode

**Usage Guide** Configure this command only in virtual switch unit (VSU) mode.

**Configuration** The following example enables BFD-based DAD.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# dual-active detection bfd
```

The following example disables BFD-based DAD.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# no dual-active detection bfd
```

The following example enables AP-based DAD.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# dual-active detection aggregateport
```

The following example disables AP-based DAD.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)#no dual-active detection aggregateport
```

**Related  
Commands**

| Command                                | Description                                   |
|----------------------------------------|-----------------------------------------------|
| <b>dual-active pair interface</b>      | Configures a DAD interface.                   |
| <b>dual-active exclude interface</b>   | Configures an exclude interface of DAD.       |
| <b>show switch virtual dual-active</b> | Displays the configuration and status of DAD. |

**Platform** N/A  
**Description**

## 7.4 dual-active exclude interface

Use this command to configure an exclude interface of DAD.

Use the **no** form of this command to remove the exclude interface setting.

**dual-active exclude interface** *interface-name*

**no dual-active exclude interface** *interface-name*

| Parameter          | Parameter             | Description    |
|--------------------|-----------------------|----------------|
| <b>Description</b> | <i>interface-name</i> | Interface name |

**Defaults** N/A

**Command Mode** config-vs-domain configuration mode

**Usage Guide** Configure this command only in VSU mode.  
An exclude interface must be a routing interface instead of a virtual switch link (VSL) interface.  
Multiple exclude interfaces are supported.

**Configuration** The following example configures interface Gi 1/1/3 as an exclude interface of DAD.

```
Ruijie(config)# interface GigabitEthernet 1/0/3
```

```
Ruijie(config-if- GigabitEthernet 1/0/3)# no switchport
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# dual-active exclude interface GigabitEthernet
1/0/3
```

| Related Commands | Command                                | Description                                   |
|------------------|----------------------------------------|-----------------------------------------------|
|                  | <b>dual-active detection</b>           | Configures DAD.                               |
|                  | <b>dual-active pair interface</b>      | Configures a DAD interface.                   |
|                  | <b>show switch virtual dual-active</b> | Displays the configuration and status of DAD. |

**Platform**  
**Description** N/A

## 7.5 dual-active interface

Use this command to configure an AP-based DAD interface.

Use the **no** form of this command to remove the setting.

**dual-active interface** *interface-name*

**no dual-active interface**

| Parameter          | Parameter             | Description                                                                       |
|--------------------|-----------------------|-----------------------------------------------------------------------------------|
| <b>Description</b> | <i>interface-name</i> | Interface type and interface number. An AP-based DAD interface must be specified. |

**Defaults** N/A

**Command Mode** config-vs-domain configuration mode

**Usage Guide** Only one AP-based detection interface can be configured. Create an AP-based interface before setting it to a detection interface. The previous detection interface will be overwritten by the current detection interface.

**Configuration** The following example configures AP 1 as the AP-based detection interface.

**Examples**

```
Ruijie(config)# interface aggregateport 1
Ruijie(config-if-AggregatePort 1)#exit
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# dual-active interface aggregateport 1
```

| Related Commands | Command                                | Description                                   |
|------------------|----------------------------------------|-----------------------------------------------|
|                  | <b>dual-active detection</b>           | Configures BFD-/AP-based DAD.                 |
|                  | <b>show switch virtual dual-active</b> | Displays the configuration and status of DAD. |

**Platform** N/A

## Description

## 7.6 port-member interface

Use this command to add a VSL-AP member interface.

Use the **no** form of this command to delete a VSL-AP member interface.

**port-member interface** *interface-name*

**no port-member interface** *interface-name*

| Parameter   | Parameter             | Description                                                               |
|-------------|-----------------------|---------------------------------------------------------------------------|
| Description | <i>interface-name</i> | Interface name, for example, GigabitEthernet 0/1 and GigabitEthernet 0/3. |

**Defaults** N/A

**Command Mode** config-vsl-port configuration mode

**Usage Guide** Configure this command in VSU mode or in standalone mode.

**Configuration Examples** The following example adds and deletes a VSL-AP member port in standalone mode.

```
Ruijie(config)# vsl-port
Ruijie(config-vsl-port)# port-member interface GigabitEthernet 0/1
Ruijie(config-vsl-port)# no port-member interface GigabitEthernet 0/2
```

The following example adds and deletes a VSL-AP member port in VSU mode.

```
Ruijie(config)# vsl-port
Ruijie(config-vsl-port)# port-member interface GigabitEthernet 1/0/1
Ruijie(config-vsl-port)# no port-member interface GigabitEthernet 1/0/1
```

| Related Commands | Command | Description |

**Platform Description** N/A

## 7.7 led-blink

Use this command to configure LED blink function.

**led-blink** {enable | disable} [**device** *device\_id*]

| Parameter   | Parameter      | Description             |
|-------------|----------------|-------------------------|
| Description | <b>enable</b>  | Enables this function.  |
|             | <b>disable</b> | Disables this function. |

|                  |           |
|------------------|-----------|
| <i>device_id</i> | Device ID |
|------------------|-----------|

**Defaults** This function is disabled by default.

**Command Mode** Privileged EXEC mode

**Usage Guide** In single-device mode, this function can be only enabled and disabled.  
 In VSU mode, a device can be specified. If not specified, all devices in the VSU will be configured.  
 If running for 30 minutes, this function is disabled automatically even without any operation.  
 The configuration cannot be saved. In case of restart or active/standby switch-over, it will be removed.

**Configuration** The following example enables and disables LED blink function.

**Examples**

```
Ruijie#led-blink enable
Ruijie#led-blink disable
```

The following example enables and disables LED blink function on Device 2.

```
Ruijie#led-blink enable device 2
Ruijie#led-blink disable device 2
```

The following example enables and disables LED blink function in VSU.

```
Ruijie#led-blink enable
Ruijie#led-blink disable
```

## 7.8 session

Use this command to perform redirection to a host or a device console.

**session { device *switch\_id* | master }**

**Parameter**

**Description**

| Parameter        | Description                                 |
|------------------|---------------------------------------------|
| <b>device</b>    | Redirects to the member device console.     |
| <i>switch_id</i> | Member device number, varying with products |
| <b>master</b>    | Redirects to the host console.              |

**Defaults**

N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command takes effect in VSU mode.

**Configuration Examples** The following example redirects the serial port console of standby device 2 to the master device console.

```
Ruijie-STANDBY#session master
Ruijie#exit
Ruijie-STANDBY#
```

The following example redirects the master device console to the console of standby device 2 and exits.

```
Ruijie#session device 2
Ruijie-STANDBY#exit
Ruijie#
```

## 7.9 show switch id

Use this command to display the device ID.

**show switch id**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration Examples** The following example displays the device ID in the standalone mode.

```
Ruijie#show switch id
Switch ID is 2
```

The following example displays the device ID in the VSU device.

```
Ruijie#show switch id
Switch ID is 1
```

**Description**

## 7.12 show switch virtual config

Use this command to display the VSU configuration of the device in standalone or VSU mode.

**show switch virtual config [ *switch\_id* ]**

| Parameter   | Parameter        | Description                                             |
|-------------|------------------|---------------------------------------------------------|
| Description | <i>switch_id</i> | Displays the VSU configuration of the specified device. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays the VSU configuration of the device in standalone mode.

**Examples**

```
Ruijie#show switch virtual config
mac: 00d0.f810.3323
```

```
!  
switch virtual domain 1  
!  
switch 1  
switch 1 priority 200  
!  
vsl-port  
port-member interface GigabitEthernet 0/1  
port-member interface GigabitEthernet 0/2  
!  
switch convert mode standalone  
!
```

The following example displays the VSU configuration of the device in VSU mode.

```
Ruijie#show switch virtual config  
switch id: 1 (mac: 00d0.f810.1111)  
!  
switch virtual domain 1  
!  
switch 1  
switch 1 priority 200  
switch 1 description switch1  
!  
vsl-port  
port-member interface GigabitEthernet 0/1  
port-member interface GigabitEthernet 0/2  
!  
Switch convert mode virtual  
!  
switch_id: 2 (mac: 00d0.f810.2222)  
!  
switch virtual domain 1

## 7.13 show switch virtual dual-active

Use this command to display the configuration of DAD.

**show switch virtual dual-active { bfd | aggregateport | summary }**

| Parameter Description | Parameter            | Description                     |
|-----------------------|----------------------|---------------------------------|
|                       | <b>bfd</b>           | Configuration of BFD-based DAD  |
|                       | <b>aggregateport</b> | Configuration of AP-based DAD   |
|                       | <b>summary</b>       | Configuration and status of DAD |

**Defaults**

N/A

**Command Mode**

Privileged EXEC mode

**Usage Guide**

N/A

**Configuration**

The following example displays the configuration and status of DAD.

**Examples**

```
Ruijie# show switch virtual dual-active summary
BFD dual-active detection enabled: Yes
Aggregateport dual-active detection enabled: No
Interfaces excluded from shutdown in recovery mode:
GigabitEthernet 1/0/3
```

```
GigabitEthernet 1/0/4
In dual-active recovery mode: No
```

The following example displays the configuration of BFD-based DAD.

```
Ruijie# show switch virtual dual-active bfd
BFD dual-active detection enabled: Yes
BFD dual-active interface configured:
    GigabitEthernet 1/0/1: UP
    GigabitEthernet 2/0/2: UP
```

The following example displays the status of AP-based DAD.

```
Ruijie# show switch virtual dual-active aggregateport
Aggregateport dual-active detection enabled: Yes
Aggregateport dual-active interface configured:
AggregatePort 1: UP
    GigabitEthernet 1/0/1: UP
    GigabitEthernet 2/0/1: UP
    GigabitEthernet 1/0/2: UP
    GigabitEthernet 2/0/2: UP
DAD relay enable AP list:
    AggregatePort 1
```

**Related  
Commands**

| Command                              | Description                      |
|--------------------------------------|----------------------------------|
| <b>dual-active detection</b>         | Enables DAD.                     |
| <b>dual-active pair interface</b>    | Configures a DAD interface.      |
| <b>dual-active exclude interface</b> | Configures an exclude interface. |

**Platform  
Description**

N/A

## 7.14 show switch virtual link

Use this command to display the status of a virtual switch link (VSL).

**show switch virtual link [ port ]**

**Parameter  
Description**

| Parameter   | Description                        |
|-------------|------------------------------------|
| <b>port</b> | Displays the port status of a VSL. |

**Defaults**

N/A

**Command Mode**

Privileged EXEC mode

**Usage Guide**

N/A

**Configuration** The following example displays VSL link information.

**Examples**

```
Ruijie# show switch virtual link
VSL-AP  State  Peer-VSL      Rx      Tx      Uptime
-----
-----
1/1     UP     2/1           100000  100000  1d,4h,29m
2/1     UP     1/1           100000  100000  1d,4h,29m
```

The following example displays VSL port information.

```
Ruijie# show switch virtual link port

switch 1:
Port                AP  State  Peer-port          Rx  Tx
  Uptime
-----
-----
GigabitEthernet 1/0/1  1  OK    GigabitEthernet 2/0/1  9000 9000
  0d,0h,20m
GigabitEthernet 1/0/2  2  OK    GigabitEthernet 2/0/2  9000 9000
  0d,0h,20m

Switch 2:
Port                AP  State  Peer-port          Rx  Tx
  Uptime
-----
-----
GigabitEthernet 2/0/1  1  OK    GigabitEthernet 1/0/1  9000 9000
  0d,0h,20m
GigabitEthernet 2/0/2  2  OK    GigabitEthernet 1/0/2  9000 9000
  0d,0h,20m
```

**Related**

**Commands**

| Command                         | Description                                         |
|---------------------------------|-----------------------------------------------------|
| <b>show switch virtual</b>      | Displays information about the VSU system.          |
| <b>show switch virtual role</b> | Displays the ID, role, and priority of each device. |

**Platform**

**Description**

N/A

## 7.15 show switch virtual role

Use this command to display the ID, role, and priority of each chassis.

**show switch virtual role**

**Parameter**

| Parameter | Description |

| <b>Usage Guide</b>           | N/A                                                                                                                                                   |           |             |     |     |

**Configuration** The following example displays the topology status.

**Examples**

```
Ruijie# show switch virtual topology
Introduction: '[num]' means switch num, '(num/num)' means vsl-aggregateport
num.

Chain Topology:
[1] (1/2) --- (2/1) [2]

Switch[1]: ACTIVE, MAC: 00d0.f822.33d6, Description: Switch1
Switch[2]: STANDBY, MAC: 1234.5678.9003, Description: Switch2
```

**Field Description**

| Field         | Description         |
|---------------|---------------------|

## 7.17 switch

Use this command to specify the ID of a device in the VSU system.

Use the **no** form of this command to restore the default setting.

**switch** *switch\_id*

**no switch**

**Parameter**

**Description**

| Parameter        | Description                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>switch_id</i> | ID of a device in the VSU system                                                                                   |
|                  |  The range depends on products. |

**Defaults**

The default is 1.

**Command Mode**

config-vs-domain configuration mode

**Usage Guide**

The device ID identifies each virtual device member. In VSU mode, the interface name format changes to "switch/slot/port" from "slot/port", in which "switch" is the device ID.

If either chassis are active or if the role of the just started chassis is uncertain and both have the same priority, the chassis with a smaller ID is elected as the active one.

This command can be only used to modify the device ID in standalone mode. In VSU mode, run the **switch renumber** command to modify the device ID. The modified device ID takes effect only

after you restart the device, regardless of in standalone mode or in VSU mode.

**Configuration** The following example sets the ID of the device whose domain ID is 1 to 2 in the VSU system.

**Examples**

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# switch 2
Ruijie(config-vs-domain)# exit
```

|------------------------------|--------------------------------------------------------------------|
| <b>switch virtual domain</b> | Modifies the domain ID of a device in standalone mode.             |
| <b>switch priority</b>       | Configures the priority of a device in the VSU system.             |
| <b>show switch virtual</b>   | Displays the domain ID as well as the ID and role of each chassis. |

**Platform**

N/A

**Description**

## 7.18 switch convert mode

Use this command to perform conversion between the standalone mode and the VSU mode.

**switch convert mode { virtual | standalone } [ switch\_id ]**

**Parameter**

**Description**

| Parameter         | Description     |
|-------------------|-----------------|
| <b>virtual</b>    | VSU mode        |
| <b>standalone</b> | Standalone mode |
| <i>switch_id</i>  | Device ID       |

**Defaults**

The device is in standalone mode by default.

**Command Mode**

Privileged EXEC mode

**Usage Guide**

After you run the **switch convert mode virtual** command, the software automatically backs up the configuration file in standalone mode, saves it as a **standalone.text** file, and then deletes the **config.text** file. The software also prompts you whether to use the **virtual\_switch.text** file to overwrite the **config.text** file, write the VSU-related configurations to the **config\_vsu\_dat** file, and then restart the device.

After you run the **switch convert mode standalone** command, the active chassis automatically backs up the configuration file in VSU mode, saves it as a **virtual\_switch.text** file, and then deletes the **config.text** file. The active chassis also prompts you whether to use the **standalone.text** file to overwrite the **config.text** file and restart the device.

The **switch convert mode** command can be used in standalone mode or in VSU mode. In standalone mode, this command is used to switch the mode of the current chassis. In VSU mode, this command is used to switch the mode of the device specified by **switch\_id** if **switch\_id** is available and to switch the mode of the active device if **switch\_id** is not available.

You are advised to first switch the mode of the standby device and then the mode of the active

mode.

**Configuration** The following example converts the device mode from the standalone mode into the VSU mode.

**Examples**

```
Ruijie# switch convert mode virtual
```

The following example switches the modes of the standby device (**switch\_id** set to **2**) and the active device (**switch\_id** set to **1**) from the VSU mode to the standalone mode.

```
Ruijie# switch convert mode standalone 2
Ruijie# switch convert mode standalone 1
```

## 7.19 switch crc

Use this command to configure parameters for frame error detection.

Use the **no** form of this command to restore the default setting.

**switch crc errors** *error\_num* **times** *time\_num*

**no switch crc**

**Parameter  
Description**

| Parameter        | Description                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>error_num</i> | Limits the number of error frames increasing from that in the last detection. If the increased number is greater than <i>error_num</i> , it is taken as an error. |
| <i>time_num</i>  | When the error count exceeds the <i>time_num</i> , the device will take actions (prompting a message or disabling the port).                                      |

**Defaults**

The default *error\_num* is 3.

The default *time\_num* is 10.

**Command Mode**

config-vs-domain configuration mode

**Usage Guide**

N/A

**Configuration**

The following example sets the *error\_time* and *time\_num* parameters to 10 and 5 respectively.

**Examples**

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)#
Ruijie(config-vs-domain)#switch crc errors 10 times 5
```

## 7.20 switch description

Use this command to configure the description for a VSU switch.

Use the **no** form of this command to remove the setting.

**switch** *switch\_id* **description** *dev-name*

**no switch** *switch\_id* **description**

| Parameter   | Parameter        | Description                                        |
|-------------|------------------|----------------------------------------------------|
| Description | <i>switch_id</i> | Device ID                                          |
|             | <i>dev_name</i>  | Device description, no greater than 32 characters. |

Defaults

N/A

Command Mode

config-vs-domain configuration mode

Usage Guide

This command is configured on a device in whether standalone or VSU mode and takes effect immediately after configuration,

Configuration

The following example configures the description for a VSU switch.

Examples

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# switch 1 description buildingA
Ruijie(config-vs-domain)# exit
```

|-------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>switch_id</i>     | ID of the running device in VSU mode.<br><br> The range depends on products. For details, see the <i>Configuration Guide</i> . |
|             | <i>new_domain_id</i> | New domain ID, in the range from 1 to 255.                                                                                                                                                                      |

**Defaults** The default *new\_domain\_id* is 100 by default.

**Command Mode** config-vs-domain configuration mode

**Usage Guide** Use this command only in VSU mode. In addition, the setting can take effect only after the device is restarted.

**Configuration Examples** The following example sets the domain ID of device 1 to 10 in VSU mode.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# switch 1 domain 10
```

The following example sets the domain ID of device 2 to 10 in VSU mode.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# switch 2 domain 10
```

The following example sets the domain ID of device 2 to the default value in VSU mode.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# no switch 2 domain
```

|                  | <b>switch virtual domain</b> | Modifies the domain ID in standalone mode.                         |
|                  | <b>show switch virtual</b>   | Displays the domain ID as well as the ID and role of each chassis. |

**Platform Description** N/A

## 7.22 switch priority

Use this command to configure the priority of a device in the VSU system.

Use the **no** form of this command to restore the default setting.

**switch** *switch\_id* **priority** *priority\_num*

**no switch** *switch\_id* **priority**

| Parameter   | Parameter        | Description                                                                                                                                                                      |
|-------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <i>switch_id</i> | ID of a device in the VSU system.<br><br> The range depends on products. For details, see the |

|                     |                                                                |
|---------------------|----------------------------------------------------------------|
|                     | <i>Configuration Guide.</i>                                    |
| <i>priority_num</i> | Priority of a device in the VSU system, ranging from 1 to 255. |

**Defaults** The default *priority\_num* is 100.

**Command Mode** config-vs-domain configuration mode

**Usage Guide** A larger value means a higher priority. The chassis with a higher priority is elected as the active chassis.  
You can use this command in standalone mode or in VSU mode. The modified priority takes effect only after you restart the device.  
In VSU mode, **switch\_id** indicates the ID of the running device. If the ID does not exist, the configuration does not effect.

**Configuration** The following example sets the priority of device 1 to **200**.

**Examples**

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# switch 1 priority 200
Ruijie(config-vs-domain)# exit
```

The following example sets the priority of device 1 to **200** and restores the priority of device 2 to the default value in VSU mode.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# switch 1 priority 200
Ruijie(config-vs-domain)# no switch 2 priority
Ruijie(config-vs-domain)# exit
```

| <i>new_switch_id</i> | ID of the new switch                                                                                                                                              |
|                      |  The range depends on products. For details, see the <i>Configuration Guide.</i> |

**Defaults** N/A

**Command Mode** config-vs-domain configuration mode

**Usage Guide** This command is configured in VSU mode. In addition and takes affect after device restart. The **no** form of this command will restore the switch ID to 1.

**Configuration** The following example modifies the ID of device 1 that is running to 2 in VSU mode.

**Examples**

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# switch 1 renumber 2
```

The following example restores the ID of device 2 that is running to the default value in VSU mode.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# no switch 2
```

Description** N/A

## 7.24 switch virtual aggregateport lff enable

Use this command to enable the locally-preferred forwarding function on the AP in VSU mode.

Use the **no** form of this command to disable this function.

**switch virtual aggregateport lff enable**

**no switch virtual aggregateport lff enable**

| Parameter          | Parameter | Description |
|--------------------|-----------|-------------|
| <b>Description</b> | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** config-vs-domain configuration mode

**Usage Guide** N/A

**Configuration** The following example enables the locally-preferred forwarding function on the AP in VSU mode.

**Examples**

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)# switch virtual aggregateport lff enable
```

**Related  
Commands**

| Command                            | Description                                  |
|------------------------------------|----------------------------------------------|
| <b>show switch virtual balance</b> | Displays the current traffic balancing mode. |

**Platform  
Description** N/A

## 7.25 switch virtual domain

Use this command to modify the domain ID of a device in standalone mode, or enter config-vs-domain configuration mode in VSU mode.

Use the **no** form of this command to restore the default setting.

**switch virtual domain** *domain\_id*

**no switch virtual domain**

**Parameter  
Description**

| Parameter        | Description                                       |
|------------------|---------------------------------------------------|
| <i>domain_id</i> | Domain ID of the VSU, in the range from 1 to 255. |

**Defaults** The default is 100.

**Command Mode** Global configuration mode

**Usage Guide** Only two devices with the same domain ID can form a virtual device. The domain ID must be unique within the local area network (LAN).

**Configuration** The following example sets the domain ID of the VSU to 1 in standalone mode.

**Examples**

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)#
```

**Related  
Commands**

| Command                    | Description                                                        |

| <b>show switch virtual</b> | Displays the domain ID as well as the ID and role of each chassis. |
| <b>switch domain</b>       | Modifies the domain ID in VSU mode.                                |

**Platform  
Description** N/A

## 7.26 switch virtual ecmp lff enable

Use this command to enable the locally-preferred forwarding function on the ECMP interface in VSU mode.

Use the **no** form of this command to disable this function.

**switch virtual ecmp lff enable**

**no switch virtual ecmp lff enable**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** This function is enabled by default.

**Command Mode** config-vs-domain configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example enables the locally-preferred forwarding function on the ECMP interface in VSU mode.

```
Ruijie(config)# switch virtual domain 1
Ruijie(config-vs-domain)#switch virtual ecmp lff enable
```

|                  | <b>show switch virtual balance</b> | Displays the current load balance mode. |

**Platform Description** N/A

## 7.27 vsl-port

Use this command to enter VSL-PORT mode

**vsl-port**

| Parameter   | Parameter | Description |
|-------------|-----------|-------------|
| Description | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is configured on a device in whether standalone mode or VSU mode.

**Configuration** The following example enters VSL-AP configuration mode on a device in standalone mode.

**Examples**

```
Ruijie(config)# vsl-port  
Ruijie(config-vsl-port)#
```

The following example enters VSL-APPORT configuration mode on a device in VSU mode.

```
Ruijie(config)# vsl-port  
Ruijie(config-vsl-port)#
```

## 8 RNS &Track Commands

### 8.1 delay

Use this command to specify a period of time after which the tracked object status will change if the interface status changes.

Use the **no** form of this command to restore the default setting.

**delay** { **up** *seconds* [ **down** *seconds* ] | [ **up** *seconds* ] **down** *seconds* }

**no delay**

| Parameter Description | Parameter                  | Description                                                                         |
|-----------------------|----------------------------|-------------------------------------------------------------------------------------|
|                       | <b>up</b> <i>seconds</i>   | Sets the delay time from down to up in the range from 0 to 180. The unit is second. |
|                       | <b>down</b> <i>seconds</i> | Sets the delay time from up to down in the range from 0 to 180. The unit is second. |

**Defaults** There is no delay by default.

**Command Mode** Track configuration mode

**Usage Guide** The continual oscillation of the tracked object status may cause the client of this tracked object changing also. This command can be used to delay advertising the change of the tracked object status. For example, the status of a tracked object changes from up to down, if the delay down 180 is configured, the down status will be advertised after 180 seconds. If the tracked object status changes to the up again in this period, it won't be advertised. For the client of the tracked object, the status of the tracked object is always up.

**Configuration Examples** The following example sets the delay time to 30 seconds when the tracked object changes to up from down.

```
Ruijie(config)# track 5 rns 10
Ruijie(config-track)# delay up 30
Ruijie(config-track)# end
```

**Platform Description** N/A

## 8.2 dns

Use this command to set an IP RNS object to send the DNS packets and to enter the IP RNS DNS mode.

**dns** {*destination-hostname* **name-server** *a.b.c.d* [ **source-ipaddr** *ip-address* ] [**out-interface** *type num* [ **next-hop** *A.B.C.D* ] ] | **oob** *destination-hostname* **name-server** *a.b.c.d* [ **source-ipaddr** *ip-address* ] **via** *type num* **next-hop** *A.B.C.D*}

| Parameter Description | Parameter                            | Description                                                                                  |
|-----------------------|--------------------------------------|----------------------------------------------------------------------------------------------|
|                       | <i>destination-hostname</i>          | Sets the destination IP address or the destination host domain name.                         |
|                       | <b>oob</b>                           | Enables management port detection.                                                           |
|                       | <i>a.b.c.d</i>                       | Sets the IP address for the DNS server.                                                      |
|                       | <i>ip-address</i>                    | Indicates the source IP address of RNS packets.                                              |
|                       | <b>out-interface</b> <i>type num</i> | Specifies the egress interface (non-management port) for RNS packets.                        |
|                       | <b>via</b> <i>type num</i>           | Specifies the management port as the egress interface (non-management port) for RNS packets. |
|                       | <i>A.B.C.D</i>                       | Specifies the next-hop IP address for RNS packets.                                           |

**Defaults** N/A

**Command Mode** IP RNS configuration mode

**Usage Guide** Use this command to set an IP RNS object to send the DNS packets and to enter the IP RNS DNS mode. If you want to change the probe type, you should delete the probe first by using the **no ip rns** command and then perform new configuration.

**Configuration Examples** The following example sets the IP RMS object to send the DNS packets.

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# dns www.ruijie.com.cn name-server 61.154.22.41
Ruijie(config-ip-rns-dns)# exit
Ruijie(config)# ip rns schedule 1 start-time now
```

| Related Commands | Command | Description |
|------------------|---------|-------------|
|                  | N/A     | N/A         |

**Platform Description** N/A

## 8.3 frequency

Use this command to set the interval of sending the packets, which must be no smaller than the timeout time.

Use the **no** form of this command to restore the default setting.

**frequency** *milliseconds*

**no frequency**

| Parameter Description | Parameter           | Description                                                                                                |
|-----------------------|---------------------|------------------------------------------------------------------------------------------------------------|
|                       | <i>milliseconds</i> | Sets the interval of sending the packets, in the range from 10 to 604,800,000 in the unit of milliseconds. |

**Defaults** The default is 60 seconds.

**Command** IP RNS ICMP echo configuration mode

**Mode** IP RNS DNS configuration mode

IP RNS TCP configuration mode

**Usage Guide** Use this command to set the interval of sending the ICMP echo or DNS packets, which must accord with the following formula to ensure accuracy:

**frequency** *milliseconds* > **timeout** *milliseconds* >= **threshold** *milliseconds*

**Configuration** The following example configures an ICMP echo probe whose destination address is 192.168.21.1.

**Examples** The frequency, timeout time and threshold are set to 30,000, 8,000 and 6,000 milliseconds respectively.

```
Ruijie(config-ip-rns)#icmp-echo 192.168.21.1
Ruijie(config-ip-rns-icmp-echo)#frequency 30000
Ruijie(config-ip-rns-icmp-echo)#timeout 8000
Ruijie(config-ip-rns-icmp-echo)#threshold 6000
```

|------------------|----------------|--------------------------------------------------|
|                  | <b>timeout</b> | Defines the timeout time of sending the packets. |

**Platform** N/A

**Description**

## 8.4 icmp-echo

Use this command to configure an ICMP echo RNS probe.

**icmp-echo** { *destination-ip-address* | *destination-hostname* [ **name-server** *ip-address* ] }

```
[ source-ipaddr ip-address ] [out-interface type num [ next-hop A.B.C.D ] ] | oob
{ destination-ip-address | destination-hostname [ name-server ip-address ] } [ source-ipaddr
ip-address ] via type num next-hop A.B.C.D
```

| Parameter Description | Parameter                              | Description                                                                                                      |
|-----------------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------|
|                       | <i>destination-hostname</i>            | Sets the destination IP address for the ICMP echo packets.                                                       |
|                       | <b>oob</b>                             | Enables management port detection.                                                                               |
|                       | <i>destination-hostname</i>            | Sets the destination host name within 127 characters. The exceeding characters are truncated automatically.      |
|                       | <b>name-server</b> <i>ip-address</i>   | Sets the domain name server. The default domain name server is configured via the <b>ip name-server</b> command. |
|                       | <b>source-ipaddr</b> <i>ip-address</i> | Sets the source IP address for the ICMP echo packets.                                                            |
|                       | <b>out-interface</b> <i>type num</i>   | Sets the egress port(non-management) for the probe packet.                                                       |
|                       | <b>via</b> <i>type num</i>             | Specifies the management port as the egress interface (non-management port) for probe packets.                   |
|                       | <b>next-hop</b> <i>A.B.C.D</i>         | Sets the next hop IP address.                                                                                    |

**Defaults** N/A

**Command Mode** IP RNS configuration mode

**Usage Guide** This command is used to enable the IP RNS object to send ICMP echo packets containing the specified destination IP address. The default payload size of an ICMP echo packet is 36 bytes. The **request-data-size** command is used to modify the packet size.

You can modify the probe parameter after specifying the type of the IP RNS probe (such as ICMP echo probe). If you want to change the probe type, you should delete the probe first by using the **no ip rns** command and then perform new configuration.

**Configuration Examples** The following example enables the IP RNS object to send the ICMP echo packets containing the destination IP address 10.1.1.1.

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# exit
Ruijie(config)# ip rns schedule 1 start-time now life forever
```

## 8.5 ip rns

Use this command to define an IP RNS operation object and to enter the IP RNS configuration mode.

Use the **no** form of this command to delete an IP RNS operation object.

```
ip rns operation-number [{dns destination-hostname name-server ip-address | icmp-echo
destination-ip-address | tcp-connect destination-ip-address port-number} [frequency seconds]
[timeout milliseconds] [threshold milliseconds]] ]
```

```
no ip rns operation-number
```

| Parameter Description | Parameter                                                                      | Description                                                                                                                                                                                                                                                                                |

For details, see the <b>threshold</b> command.                                                                                                                                                                                |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** Currently, the RNS supports only IPv4-related tests, but not IPv6-related tests. At most 500 tests can be configured, depending on the performance of devices. The test function is only a value-added function. When a large number of tests are configured and consume a lot of system resources, the test function may be temporary disabled to ensure normal operation of core services, such as route forwarding.

Detailed configuration (executing mandatory items of **ip rns** *operation-number*): Run this command and enter the IP-RNS configuration mode. In this mode, you can define various test types. If the test type is not configured, the RNS test is not created. After configuring an RNS test, you must run the **ip rns schedule** command to configure its schedule parameters; otherwise, the test cannot be conducted.

After configuring the type of an RNS test, you can run the **ip rns** command to enter the mode of the

test type. To modify the type of an RNS instance, you need to first delete the RNS instance by running the **no ip rns** command in global configuration mode.

**Configuration** The following example defines the IP RNS object 1.

**Examples**

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# threshold 10000
Ruijie(config-ip-rns-icmp-echo)# timeout 20000
Ruijie(config-ip-rns-icmp-echo)# frequency 30000
Ruijie(config-ip-rns-icmp-echo)# exit
Ruijie(config)# ip rns schedule 1 start-time now life forever
```

| <b>never</b>                                                               | Never triggers operation.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>xofy</b> [ x-value y-value ]                                            | X probes among the latest Y ones exceed the threshold range. The valid X range is from 1 to 16 and the default is 5. The valid Y range is from 1 to 16 and the default is 5.                                                                                                                                                                                                                                                                        |
| <b>threshold-value</b><br><i>upper-threshold</i><br><i>lower-threshold</i> | Configures upper and lower thresholds.<br>When <i>monitored-element</i> is <b>rtt</b> , this parameter indicates time, in the range from 0 to 60,000 milliseconds. See <b>Usage Guide</b> for the default setting.<br>When react type is timeout, you don't need to configure this parameter.                                                                                                                                                       |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** One IP RNS object can be configured with multiple thresholds monitoring, each for one element. Monitored elements that are supported vary with different probe types.

| monitored-element | icmp-echo | dns | tcp-connect |
|-------------------|-----------|-----|-------------|
| timeout           | ✓         | ✓   | ✓           |
| rtt               | ✓         | ✓   | ✓           |

The default thresholds for monitored elements are listed as follows:

| Monitored Element | Upper Threshold | Lower Threshold |
|-------------------|-----------------|-----------------|
| timeout           | -               | -               |
| rtt               | 5000 ms         | 0 ms            |

**Configuration** The following example configures RNS1 and its threshold monitoring.

```
Examples Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 192.168.23.1
```

```
Ruijie(config-ip-rns-icmp-echo)# exit
Ruijie(config)# ip rns schedule 1 start-time now life forever
Ruijie(config)# ip rns reaction-configuration 1 react timeout threshold-type
immediate action-type triggerOnly
```

**Related

**Description**

## 8.7 ip rns reaction-trigger

Use this command to enable the IP RNS probe which exceeds the monitoring threshold to trigger another IP RNS probe which is in the pending state.

Use the **no** form of this command to restore the default setting.

**ip rns reaction-trigger** *operation-number target-operation*

**no ip rns reaction-trigger** *operation-number target-operation*

**Parameter  
Description**

| Parameter               | Description                                             |
|-------------------------|---------------------------------------------------------|
| <i>operation-number</i> | The source operation number, in the range from 1 to 500 |
| <i>target-operation</i> | The target operation number, in the range from 1 to 500 |

**Defaults**

N/A

**Command  
Mode**

Global configuration mode

**Usage Guide**

The trigger function is applied in network fault diagnosis scenario

**Configuration**

The following example enables IP RNS1 to trigger IP RNS 2.

**Examples**

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo www.google.com
Ruijie(config-ip-rns-icmp-echo)# exit
Ruijie(config)# ip rns schedule 1 start-time now life forever
Ruijie(config)# ip rns reaction-configuration 1 react timeout threshold-type
immediate action-type trigger
Ruijie(config)# ip rns 2
Ruijie(config-ip-rns)# dns www.baidu.com name-server 8.8.8.8
Ruijie(config-ip-rns-dns)# exit
Ruijie(config)# ip rns reaction-trigger 1 2
```

**Description**

## 8.8 ip rns reset

Use this command to clear all IP RNS configuration.

**ip rns reset**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to clear all IP RNS configuration. This command is used only in extreme cases (for example, RNS probe configuration is wrong).

**Configuration Examples** The following example clears all IP RNS configuration.

```
Ruijie(config)# ip rns reset
```

**Description**

## 8.9 ip rns restart

Use this command to restart the IP RNS probe.

**ip rns restart operation-number**

| Parameter Description | Parameter               | Description                                                          |
|-----------------------|-------------------------|----------------------------------------------------------------------|
|                       | <i>operation-number</i> | Sets the IP RNS operation object number, in the range from 1 to 500. |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to restart the IP RNS probe whose schedule is in the pending state. This command is invalid for the IP RNS probe not configured with the scheduling policy.

**Configuration** The following example restarts IP RNS 1.

**Examples** Ruijie(config)# ip rns restart 1

## 8.10 ip rns schedule

Use this command to configure the scheduling strategy, start time and survival time for the IP RNS probe. Use the **no** form of this command to restore the default setting.

**ip rns schedule** operation-number [ **life** { **forever** | *seconds* } ] [ **start-time** { *hh:mm* [ *:ss* ] [ *month day* | *day month* ] } | **pending** | **now** | **after** *hh:mm:ss* } ] [ **recurring** ]

**no ip rns schedule** operation-number

| Parameter Description | Parameter                    | Description                                                                                                                 |
|-----------------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
|                       | <i>operation-number</i>      | RNS operation index, in the range from 1 to 500                                                                             |
|                       | <b>life forever</b>          | The RNS operation is valid forever.                                                                                         |
|                       | <b>life</b> <i>seconds</i>   | The RNS survival time, measured in seconds                                                                                  |
|                       | <i>hh:mm</i> [ <i>:ss</i> ]  | Defines the time when the operation starts,                                                                                 |
|                       | <i>month</i>                 | The month when the operation starts, in the range from January (Jan.) to December (Dec.). The default is the current month. |
|                       | <i>day</i>                   | The day when the operation starts, in the range from 1 to 31. The default is the current day.                               |
|                       | <b>pending</b>               | The start time is pending.                                                                                                  |
|                       | <b>now</b>                   | The operation starts right now.                                                                                             |
|                       | <b>after</b> <i>hh:mm:ss</i> | The operation starts after hh hours, mm minutes and ss seconds.                                                             |
|                       | <b>recurring</b>             | The operation starts automatically as scheduled every day.                                                                  |

**Defaults** The IP RNS probe is in the pending state by default. In other words, the probe is not performed unless it is triggered by another RNS probe.

**Command** Global configuration mode  
**Mode**

**Usage Guide** The **ip rns schedule** command is used to configure the IP RNS probe with scheduling policy. Once the scheduling policy is configured, the RNS probe cannot be modified. You can modify the RNS probe after deleting the schedule with the **no ip rns schedule** command.  
 Life {seconds} refers to the survival time of the IP RNS probe. The probe will end after the survival time.

**Configuration** The following example configures the RNS probe with scheduling policy.

**Examples**

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# exit
Ruijie(config)# ip rns schedule 1 start-time now life forever
```

Once the scheduling policy is configured, the RNS probe cannot be modified. The RNS probe can be modified after the schedule is deleted.

```
Ruijie(config)# ip rns 1
Entry already running and cannot be modified
    (only can delete (no) and start over)
    (check to see if the probe has finished exiting)
Ruijie(config)# no ip rns schedule 1
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns-icmp-echo)# exit
```

**Platform** N/A  
**Description**

## 8.11 object

Use this command to add a tracked object to the object track list.

Use the **no** form of this command to delete a traced object.

**object** *object-number* [ **not** ]

**no object** *object-number*

**Parameter Description**

| Parameter            | Description                                       |
|----------------------|---------------------------------------------------|
| <i>object-number</i> | Tracked object number, in the range from 1 to 700 |

**Defaults** No tracked object is configured by default.

**Command** Track configuration mode  
**Mode**

**Usage Guide** This command is used to add a tracked object to the object track list. The number of tracked objects is only restricted by the track list capacity.

**object** *object-number*: The tracked object must be in the up state for the track list to be in the up state.

**object** *object-number* not: track: The tracked object must be in the up state for the track list to be in the up state,

- This command is configured only in track configuration mode for the track list.
- The object cannot track itself.
- The objects cannot track each other. For example, if A tracks B, B cannot track A. Otherwise, both A and B are in oscillation.

**Configuration Examples** The following example adds tracked object 4 to the object track list. When object 1 is in the up state, 2 down, 3 up, object 4 is in the up state.

```
Ruijie(config)# track 4 list boolean and
Ruijie(config-track)# object 1
Ruijie(config-track)# object 2 not
Ruijie(config-track)# object 3
Ruijie(config-track)# end
```

## 8.12 request-data-size

Use the following example to set the protocol payload size of IP RNS probe packet.

Use the **no** form of this command to restore the default setting.

**request-data-size** *bytes*

**no request-data-size**

**Parameter Description**

| Parameter    | Description                                                                                  |
|--------------|----------------------------------------------------------------------------------------------|
| <i>bytes</i> | The number of payload bytes. The minimum/maximum number of bytes varies with the probe type. |

**Defaults** The default is the minimum payload byte, which varies with the probe type.

**Command Mode** IP RNS ICMP echo configuration mode

**Usage Guide** This command is used to fill bytes in the probe packet to probe for the bigger packet.

| Probe Type | Range        | Default |
|------------|--------------|---------|
| icmp-echo  | [ 36, 1472 ] | 36      |

**Configuration** The following example sets the protocol payload size of the IP RNS probe packet to 50.

**Examples**

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# request-data-size 50
Ruijie(config-ip-rns-icmp-echo)# exit
```

## 8.13 show ip rns collection-statistics

Use this command to display statistics about the RNS probe.

**show ip rns collection-statistics** [ *operation-number* ]

**Parameter Description**

| Parameter               | Description                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------|
| <i>operation-number</i> | Sets the IP RNS operation object number, in the range from 1 to 500.<br>The default is all IP RNS operation objects. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display statistics about an IP RNS probe.

**Configuration** The following example displays statistics about the all RNS probes.

**Examples**

```
Ruijie#show ip rns collection-statistics 1
Entry number: 1
Start Time Index: *2014-03-20 19:53:51
Number of successful operations: 919
```

```

Number of operations over threshold: 0
Number of failed operations due to a Disconnect: 0
Number of failed operations due to a Timeout: 2
Number of failed operations due to a Busy: 0
Number of failed operations due to a No Connection: 0
Number of failed operations due to an Internal Error: 2
Number of failed operations due to a Sequence Error: 0
Number of failed operations due to a Verify Error: 0
RTT Values:
RTTAvg: 18      RTTMin: 16      RTTMax: 37
NumOfRTT: 919  RTTSum: 16654    RTTSum2: 302786

```

## 8.14 show ip rns configuration

Use this command to display the RNS instance configuration.

**show ip rns configuration** [ *operation-number* ]

| Parameter Description | Parameter               | Description                                               |
|-----------------------|-------------------------|-----------------------------------------------------------|
|                       | <i>operation-number</i> | Sets the RNS instance number, in the range from 1 to 500. |

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display the RNS instance configuration. The configuration varies with different packet types.

**Configuration** The following example displays the RNS 1 configuration.

### Examples

```
Ruijie# show ip rns configuration 1
Entry number: 1
Tag: ruijie555
Type of operation to perform: icmp-echo
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 10000
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): 3500
Next Scheduled Start Time:Start Time already passed
Target address/Source address: 2.2.2.3/0.0.0.0
Request size (ARR data portion): 36
```

| Field                              | Description                     |
|------------------------------------|---------------------------------|
| Entry number                       | IP RNS operation index          |
| Tag                                | Instance tag.                   |
| Type of operation to perform       | Operation type.                 |
| Operation timeout (milliseconds)   | Operation timeout.              |
| Operation frequency (milliseconds) | Operation frequency.            |
| Threshold (milliseconds)           | Threshold.                      |
| Recurring (Starting Everyday)      | The operation starts every day. |
| Life (seconds)                     | Life time                       |
| Next Scheduled Start Time          | Next scheduled start time.      |
| Target address/Source address      | Target address/Source address   |
| Request size (ARR data portion)    | Request packet size.            |

**Description**

## 8.15 show ip rns operational-state

Use this command to display operational state.

**show ip rns operational-state** [ *operation-number* ]

| Parameter Description | Parameter               | Description                                                                                                    |
|-----------------------|-------------------------|----------------------------------------------------------------------------------------------------------------|
|                       | <i>operation-number</i> | Sets the IP RNS operation object number, in the range from 1 to 500. The default is all RNS operation objects. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display the state information about an RNS probe.

**Configuration** The following example displays the state information about all RNS probes.

### Examples

```
Ruijie# show ip rns operational-state
Entry number: 1
Modification time: *2014-01-10 10:26:14
Current seconds left in Life: Forever
Operational state of entry: Active
Number of Octets Used by this Entry: 2272
Number of operations attempted: 232
Number of operations skipped: 0
Connection loss occurred: FALSE
Timeout occurred: FALSE
Over thresholds occurred: FALSE
Latest RTT (milliseconds): 4
Latest operation start time: 2014-01-10 10:26:55
Latest operation return code: OK
```

| Field                               | Description                                                                                 |
|-------------------------------------|---------------------------------------------------------------------------------------------|
| Entry number                        | IP RNS operation index                                                                      |
| Modification time                   | Probe result recounting time (every time schedule is enabled, the result is counted again). |
| Number of Octets Used by this Entry | Number of octets contained in the probe packet.                                             |
| Number of operations attempted      | Number of attempted operation.                                                              |

|                              |                                                      |
|------------------------------|------------------------------------------------------|
| Number of operations skipped | Number of failed operation.                          |
| Current seconds left in Life | Probes for the left life.                            |
| Operational state of entry   | Probes for the operational state (Active/Disactive). |
| Connection loss occurred     | Connection loss occurred.                            |
| Timeout occurred             | Send request timeout occurred.                       |
| Over thresholds occurred     | Threshold violation occurred.                        |
| Latest RTT (milliseconds)    | Latest RTT.                                          |
| Latest operation start time  | Latest operation start time.                         |
| Latest operation return code | Latest operation return code.                        |

**Platform** N/A  
**Description**

## 8.16 show ip rns reaction-configuration

Use this command to display the proactive threshold monitoring information of an IP RNS probe.

**show ip rns reaction-trigger** [ *operation-number* ]

**Parameter Description**

| Parameter               | Description                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------|
| <i>operation-number</i> | The number of IP RNS operation objects, in the range from 1 to 500. The default is all RNS operation objects. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display the proactive threshold monitoring information of an IP RNS probe.

**Configuration Examples** The following example displays the proactive threshold monitoring information of all IP RNS probes.

```
Ruijie#show ip rns reaction-configuration
Entry number: 1
Reaction: rtt
Threshold Type: Never
Rising (milliseconds): 5000
Falling (milliseconds): 3000
Threshold Count: 5
```

```

Threshold Count2: 5
Action Type: trigger
Reaction: timeout
Threshold Type: Never
Threshold Count: 5
Threshold Count2: 5
Action Type: trigger
    
```

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Entry number           | IP RNS operation index                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Reaction               | Monitored object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Threshold Type         | The available parameters are listed as follows:<br><b>never</b> : Never triggers operation.<br><b>consecutive</b> : Triggers operation when the value of monitored element exceeds the threshold range for <i>occurrences</i> consecutive times.<br><b>average</b> : Triggers operation when the average value of <b>number-of-measurements consecutive times</b> exceeds the threshold range.<br><b>immediate</b> : Triggers operation immediately when the value of monitored element exceeds the threshold range.<br><b>xofy</b> : X probes among the latest Y ones exceed the threshold range. |
| Rising (milliseconds)  | Upper threshold                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Falling (milliseconds) | Lower threshold                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Threshold Count        | The parameter refers to the x value when the threshold-type is <b>xofy</b> or the average count when the threshold-type is <b>average</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Threshold Count2       | The parameter refers to the y value when the threshold-type is <b>xofy</b> or the consecutive count when the threshold-type is <b>consecutive</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Action Type            | Action type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## 8.17 show ip rns reaction-trigger

Use this command to display the reaction trigger information for all RNS objects.

**show ip rns reaction-trigger** [ *operation-number* ]

| Parameter Description | Parameter               | Description                                                                                                     |
|-----------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------|
|                       | <i>operation-number</i> | The number of IP RNS operation object, in the range from 1 to 500.<br>The default is all RNS operation objects. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** This command is used to display the reaction trigger information for all RNS objects.

**Configuration** The following example displays the reaction trigger information for all RNS objects.

### Examples

```
Ruijie#show ip rns reaction-trigger
Entry number: 1
Target rns index: 2
Status of Entry (SNMP RowStatus): active
Operational State: pending
```

| Field                            | Description            |
|----------------------------------|------------------------|
| Entry number                     | RNS index              |
| Target rns index                 | Target RNS index       |
| Status of Entry (SNMP RowStatus) | Status of RNS entry    |
| Operational State                | Reaction-trigger state |

| Related Commands | Command | Description |

## 8.18 show ip rns statistics

Use this command to display the RNS object statistics.

**show ip rns statistics** [ *operation-number* ]

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|                         |                                                                     |
|-------------------------|---------------------------------------------------------------------|
| <i>operation-number</i> | Sets the IP RNS operation object number, in the range from 1 to 500 |
|-------------------------|---------------------------------------------------------------------|

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** The statistics vary with different packet types.

**Configuration** The following example displays the RNS object statistics.

**Examples**

```
Ruijie#show ip rns statistics 1
Round trip time(RTT) Index 1
Operation time to live: Forever
Latest RTT: 1 ms
Latest operation start time: 2014-01-20 10:21:38
Latest operation return code: OK
Number of successes: 386
Number of failures: 12
```

## 8.19 show track

Use this command to display statistics of the tracked object.

**show track** [ *track-number* ]

**Parameter Description**

| Parameter           | Description                                                 |
|---------------------|-------------------------------------------------------------|
| <i>track-number</i> | Sets the tracked object number, in the range from 1 to 700. |

**Defaults** N/A

**Command Mode** Privileged EXEC mode

**Usage Guide** N/A

**Configuration** The following example displays statistics of all tracked objects.

**Examples**

```
Ruijie#show track
Track 1
  Reliable Network Service 5
  The state is Up
    1 change, current state last: 120 secs
  Delay up 30 secs, down 50 secs
Track 3
  Interface FastEthernet 1/0
  The state is Down, delayed Up (5 secs remaining)
    3 change, current state last: 300 secs
  Delay up 60 secs, down 60 secs
Track 4
  List boolean and
  Object 1
  Object 2 not
  The state is Up
    1 change, current state last: 100 secs
  Delay up 0 secs, down 0 secs
```

| Field                                        | Description                                                         |
|----------------------------------------------|---------------------------------------------------------------------|
| Track x                                      | Tracked object ID                                                   |
| Reliable Network Service x                   | Tracked RNS object                                                  |
| The state is x                               | Tracked object state                                                |
| x change                                     | Tracked object change count                                         |
| current state last: x secs                   | The time for which the current state lasts                          |
| Delay up x secs, down x secs                 | The delay state of the tracked object                               |
| Interface x x                                | Tracked interface                                                   |
| The state is x, delayed y (c secs remaining) | The tracked object state is x, and will turn to y in c seconds.     |
| List boolean and                             | The Boolean expression enables calculation by using "and" operator. |
| Object x                                     | Object x is in the up state.                                        |
| Object x not                                 | Object x is in the down state.                                      |

## 8.20 tag

Use this command to set the tag for IP RNS probe.

Use the **no** form of this command to restore the default setting.

**tag** *text*

**no tag**

| Parameter Description | Parameter   | Description                                                                        |
|-----------------------|-------------|------------------------------------------------------------------------------------|
|                       | <i>text</i> | Sets the tag for IP RNS probe, which is composed of up to 79 printable characters. |

**Defaults** N/A

**Command** IP RNS DNS configuration mode

**Mode** IP RNS ICMP echo configuration mode

**Usage Guide** Tag is used to identify the probe. When the tag exceeds 79 characters, the surplus characters are truncated.

**Configuration** The following example sets the tag for IP RNS probe to telecom gateway.

### Examples

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# tag telecom_gateway
Ruijie(config-ip-rns-icmp-echo)# exit
```

**Description**

## 8.21 tcp-connect

Use this command to configure TCP connectivity probe.

**tcp-connect** { *destination-ip-address* | *destination-hostname* [ **name-server** *ip-address* ] }  
*port-number*

| Parameter Description | Parameter                     | Description             |
|-----------------------|-------------------------------|-------------------------|
|                       | <i>destination-ip-address</i> | Destination IP address  |
|                       | <i>destination-hostname</i>   | Destination domain name |

|                                      |                              |
|--------------------------------------|------------------------------|
| <b>name-server</b> <i>ip-address</i> | IP address of the DNS server |
| <i>port-number</i>                   | TCP port number              |

**Defaults** N/A

**Command Mode** IP RNS configuration mode

**Usage Guide** TCP connectivity probe detects the connection with the TCP server.  
If no peer TCP server exist, enable the IP RNS server function on peer Ruijie devices.

**Configuration** The following example configures TCP connectivity probe.

**Examples**

```
Ruijie(config)# ip rns 1
Ruijie(config)# tcp-connect www.ruijie.net name-server 8.8.8.8 999
Ruijie(config-ip-rns-tcp-connect)# exit
Ruijie(config)# ip rns schedule 1 start-time now life forever
```

## 8.22 threshold

Use this command to configure the upper threshold value for IP RNS probe.

Use the **no** form of this command to restore the default setting.

**threshold** *milliseconds*

**no threshold**

**Parameter Description**

| Parameter           | Description                                                                                |
|---------------------|--------------------------------------------------------------------------------------------|
| <i>milliseconds</i> | Sets the upper threshold value, in the range from 0 to 60,000 in the unit of milliseconds. |

**Defaults** The default is 5,000 milliseconds.

**Command Mode** IP RNS DNS configuration mode  
**Mode** IP RNS ICMP echo configuration mode  
IP RNS TCP configuration mode

**Usage Guide** The threshold value must be no greater than the timeout value. See **Usage Guide** of the **frequency** command for the relationship among timeout, frequency and threshold.

**Configuration** The following example sets the upper threshold value for IP RNS probe to 8,000 milliseconds.

**Examples**

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# threshold 8000
Ruijie(config-ip-rns-icmp-echo)# exit
```

**Platform** N/A

**Description**

## 8.23 timeout

Use this command to set the timeout time of an IP RNS probe.

Use the **no** form of this command to restore the default setting.

**timeout** *milliseconds*

**no timeout**

**Parameter  
Description**

| Parameter           | Description                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>milliseconds</i> | Sets the timeout time, in the range from 10 to 604,800,000 in the unit of milliseconds. The default is 5,000 milliseconds. |

**Defaults**

The default timeout of an IP RNS probe varies with the detection type, which can be displayed by using **show ip rns configuration** command.

**Command** IP RNS ICMP echo configuration mode

**Mode** IP RNS DNS configuration mode

IP RNS TCP configuration mode

**Usage Guide**

The timeout value must be no smaller than the threshold value. See **Usage Guide** of the **frequency** command for the relationship among timeout, frequency and threshold.

**Configuration** The following example sets the timeout time of an IP RNS probe to 10,000 milliseconds.

**Examples**

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# timeout 10000
Ruijie(config-ip-rns-icmp-echo)# exit
```

**Related  
Commands**

| Command | Description |
|---------|-------------|
|---------|-------------|

|                                      |                                           |
|--------------------------------------|-------------------------------------------|
| <b>frequency</b> <i>milliseconds</i> | Sets the interval of sending the packets. |
|--------------------------------------|-------------------------------------------|

**Platform** N/A

**Description**

## 8.24 tos

Use this command to set the Type of Service (ToS) field in the IPv4 header of an IP RNS probe packet.

Use the **no** form of this command to restore the default setting.

**tos** *number*

**no tos**

**Parameter Description**

| Parameter     | Description                                                                                  |
|---------------|----------------------------------------------------------------------------------------------|
| <i>number</i> | Sets the ToS field in the IPv4 header of an IP RNS probe packet, in the range from 0 to 255. |

**Defaults** The default is 0.

**Command** IP RNS DNS configuration mode

**Mode** IP RNS ICMP echo configuration mode

IP RNS TCP configuration mode

**Usage Guide** ToS is an 8-bit field of an IPv4 packet. ToS can be used to set probe packet priority. Different ToS corresponds to different priority.

**Configuration Examples** The following example sets the ToS field in the IPv4 header of an IP RNS probe packet to 128.

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 10.1.1.1
Ruijie(config-ip-rns-icmp-echo)# tos 128
Ruijie(config-ip-rns-icmp-echo)# exit
```

**Description**

## 8.25 track interface line-protocol

Use this command to configure a tracked object to track the interface status and enter the track mode.

Use the **no** form of this command to delete a tracked object.

**track** *object-number* **interface** *interface-type* *interface-number* **line-protocol**

**no track** *object-number*

| Parameter Description | Parameter                                        | Description                                               |
|-----------------------|--------------------------------------------------|-----------------------------------------------------------|
|                       | <i>object-number</i>                             | Sets the tracked object number, in the range of 1 to 700. |
|                       | <i>interface-type</i><br><i>interface-number</i> | Sets the interface type and the interface number.         |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure a tracked object to track the link state of the interface. If the link state of the interface is up, the state of the corresponding tracked object is up too.

**Configuration Examples** The following example configures the object "track 3" to track the link state of ethernet 0/1.

```
Ruijie(config)# track 3 interface ethernet 0/1 line-protocol
```

| Related Commands | Command           | Description                                                                 |
|------------------|-------------------|-----------------------------------------------------------------------------|
|                  | <b>track rns</b>  | Configures a tracked object to track the operating status of an rns object. |
|                  | <b>show track</b> | Displays the tracked object related information.                            |

**Platform** N/A

**Description**

## 8.26 track list

Use this command to configure a tracked list object and specify the state of the tracked list based on a Boolean calculation.

Use the **no** form of this command to restore the default setting.

**track** *object-number* **list boolean { and | or }**

**no track** *object-number*

| Parameter Description | Parameter            | Description                                                        |
|-----------------------|----------------------|--------------------------------------------------------------------|
|                       | <i>object-number</i> | Sets the number of the tracked object, in the range from 1 to 700. |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** This command is used to configure a tracked list object and specify the state of the tracked list based on a Boolean calculation

- **track *object-number* list boolean and:** Configure a tracked list with a Boolean expression using “AND” operator.
- **track *object-number* list boolean or:** Configure a tracked list with a Boolean expression using “OR” operator.

**Configuration Examples** The following example configures tracked list object “4” and specifies the state of the tracked list based on a Boolean calculation using operator “AND”.

```
Ruijie(config)# track 4 list boolean and
```

**Related Commands**

| Command | Description |

| N/A     | N/A         |

**Platform Description** N/A

## 8.27 track rns

Use this command to configure a tracked object to track the operating status of an RNS object and enter the track mode.

Use the **no** form of this command is used to delete a tracked object.

**track *object-number* rns *entry-number***

**no track *object-number***

**Parameter Description**

| Parameter            | Description                                                 |
|----------------------|-------------------------------------------------------------|
| <i>object-number</i> | Sets the tracked object number, in the range from 1 to 700. |
| <i>entry-number</i>  | Sets the RNS object number, in the range from 1 to 500.     |

**Defaults** N/A

**Command Mode** Global configuration mode

**Usage Guide** The RNS object status is determined by whether the response packets are received. If so, the RNS object status is up and the status of the corresponding tracked object that tracks this RNS is also up.

**Configuration** The following example configures the object “track 5” to track the RNS instance “rns 7”.

**Examples** `Ruijie(config)# track 5 rns 7`

**Related Commands**

| Command                                   | Description                                                  |
|-------------------------------------------|--------------------------------------------------------------|
| <b>track interface line-protocol</b>      | Tracks the status of one interface and enter the track mode. |
| <b>show track</b> [ <i>track-number</i> ] | Displays the tracked object related information.             |

**Platform** N/A

**Description**

## 8.28 track rns-list

Use this command to configure a tracked object to track the detection result of an RNS list instance.

Use the **no** form of this command to delete a tracked object.

**track** *object-number* **rns-list** *men-list* { **and** | **or** }

**no track** *object-number*

**Parameter Description**

| Parameter            | Description                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>object-number</i> | Indicates the number of the tracked object. The value ranges from 1 to 700.                                                                                                                                                                                                                               |
| <i>men-list</i>      | Indicates the RNS list to be tracked. The value can be an RNS detection instance or a range of RNS detection instances. The instance range begins with a smaller RNS ID, ends with a larger RNS ID and is separated with an en dash (–), for example, 10–20. The value of an RNS ID ranges from 1 to 500. |

**Defaults** N/A

**Command Mode** Global configuration mode

**Default Level** 1

**Usage Guide** This command is used to configure a tracked object and specify the status of an RNS list based on a Boolean calculation.

- **track** *object-number* **rns-list** *men-list* **and**: Configures a tracked object to track the status of a tracked list with a Boolean expression using the "AND" operator.
- **track** *object-number* **rns-list** *men-list* **or**: Configures a tracked object to track the status of an RNS list with a Boolean expression using the "OR" operator.

**Configuration Examples** The following example configures tracked object numbered 5 to track RNS instances numbered 1, 2–5, and 8.

```
Ruijie(config)# track 5 rns-list 1,2-5,8 and
```

|                             |                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Verification</b>         | Run the <b>show track</b> command to display statistics of the tracked object.                                                                                                                                                                                                                                                                                                             |
| <b>Prompts</b>              | <p>1. If resources on the device are insufficient when a tracked object is configured, an error will be displayed.</p> <pre>Failed to create track obj, no resource.</pre> <p>2. If the <b>no track</b> command is executed to delete a specified tracked object but this object does not exist on the device, an error will be displayed.</p> <pre>the track object does not exist.</pre> |
| <b>Common Errors</b>        | 1. A tracked object is configured to track an RNS list but the relevant RNS instance is not configured.                                                                                                                                                                                                                                                                                    |
| <b>Platform Description</b> | N/A                                                                                                                                                                                                                                                                                                                                                                                        |

## 8.29 vrf

Use this command to set the VRF where the IP RNS probe resides.

Use the **no** form of this command to restore the default setting.

**vrf** *vrf-name*

**no vrf**

| Parameter Description | Parameter       | Description        |
|-----------------------|-----------------|--------------------|
|                       | <i>vrf-name</i> | Sets the VRF name. |

**Defaults** N/A

**Command** IP RNS ICMP echo configuration mode

**Mode** IP RNS DNS configuration mode

IP RNS TCP configuration mode

**Usage Guide** N/A

**Configuration Examples** The following example sets the VRF where the IP RNS probe resides to VPN1.

```
Ruijie(config)# ip rns 1
Ruijie(config-ip-rns)# icmp-echo 192.168.23.1
Ruijie(config-ip-rns-icmp-echo)# vrf VPN1
Ruijie(config-ip-rns-icmp-echo)# exit
Ruijie(config)# ip rns schedule 1 start-time now life forever
```

# 1 SNMP Commands

## 1.1 clear snmp locked-ip

Use this command to clear the source IP addresses which are locked after continuous SNMP authentication failures.

**clear snmp locked-ip** [ **ipv4** *ipv4-address* | **ipv6** *ipv6-address* ]

| Parameter Description | Parameter                       | Description                      |
|-----------------------|---------------------------------|----------------------------------|
|                       | <b>ipv4</b> <i>ipv4-address</i> | Clears a specified IPv4 address. |
|                       | <b>ipv6</b> <i>ipv6-address</i> | Clears a specified IPv6 address. |

**Defaults** N/A

**Command mode** Privileged EXEC mode.

**Usage Guide** Use this command to clear the source IP addresses which are locked after continuous SNMP authentication failures. You can clear the whole source IP address table or a specific source IP address.

After the source IP addresses locked are cleared, the SNMP packets with these source IP addresses could be authenticated again.

**Configuration Examples** The following example clears the whole source IP address table locked after continuous SNMP authentication failures.

```
Ruijie#clear snmp locked-ip
```

**Platform Description** N/A

## 1.2 no snmp-server

Use this command to disable the SNMP agent function.

**no snmp-server**

| Parameter | Parameter | Description |
|-----------|-----------|-------------|
|-----------|-----------|-------------|

|                    |     |     |
|--------------------|-----|-----|
| <b>Description</b> |     |     |
|                    | N/A | N/A |

**Defaults** SNMP agent is enabled by default.

**Command mode** Global configuration mode.

**Usage Guide** This command disables the SNMP agent services of all versions supported on the device.

**Configuration** The following example disables the SNMP agent.

**Examples** Ruijie(config)# **no snmp-server**

**Description**

## 1.3 show snmp

Use this command to display the SNMP configuration.

**show snmp [ mib | user | view | group | host | locked-ip | process-mib-time ]**

| <b>Parameter Description</b> | Parameter               | Description                                                                            |
|------------------------------|-------------------------|----------------------------------------------------------------------------------------|
|                              | <b>mib</b>              | Displays the SNMP MIBs supported.                                                      |
|                              | <b>user</b>             | Displays the SNMP user information.                                                    |
|                              | <b>view</b>             | Displays the SNMP view information.                                                    |
|                              | <b>group</b>            | Displays the SNMP user group information.                                              |
|                              | <b>host</b>             | Displays the explicit host configuration.                                              |
|                              | <b>locked-ip</b>        | Displays the source IP addresses locked after continuous SNMP authentication failures. |
|                              | <b>process-mib-time</b> | Displays the MIB node requiring the longest processing time.                           |

**Defaults** N/A

**Command mode** Privileged EXEC mode.

**Usage Guide** N/A

**Configuration** The example below displays the SNMP configuration:

```

Examples Ruijie# show snmp
Chassis: 60FF60
0 SNMP packets input
    0 Bad SNMP version errors
    0 Unknown community name
    0 Illegal operation for community name supplied
    0 Encoding errors
    0 Number of requested variables
    0 Number of altered variables
    0 Get-request PDUs
    0 Get-next PDUs
    0 Set-request PDUs
0 SNMP packets output
    0 Too big errors (Maximum packet size 1472)
    0 No such name errors
    0 Bad values errors
    0 General errors
    0 Response PDUs
    0 Trap PDUs
SNMP global trap: disabled
SNMP logging: disabled
SNMP agent: enabled
    
```

**Related Commands**

| Command                       | Description                                |

| <b>snmp-server chassis-id</b> | Specifies the SNMP system sequence number. |

**Platform** N/A  
**Description**

### 1.4 snmp trap link-status

Use this command to enable the interface to send link traps. Use the **no** form of this command to disable the interface to send link traps.

- snmp trap link-status**
- no snmp trap link-status**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** Sending link traps on the interface is enabled by default. If the interface link status changes, SNMP link traps will be sent.

**Command mode** Interface configuration mode

**Usage Guide** This command can be configured on the Ethernet interface, aggregate ports and SVI interfaces.

**Configuration** The following example disables the interface to send link traps.

**Examples**

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# no snmp trap link-status
```

The following example enables the interface to send link traps.

```
Ruijie(config)# interface gigabitEthernet 1/1
Ruijie(config-if-GigabitEthernet 1/1)# snmp trap link-status
```

**Platform Description** N/A

## 1.5 snmp-server authentication attempt

Use this command to configure the maximum number of continuous SNMP authentication failures, and specified the action policy for the authentication failure. Use the **no** form of this command to remove the limit of continuous SNMP authentication failures and the related action policies.

**snmp-server authentication attempt *times* exceed { lock | lock-time *minutes* | unlock }**

**no snmp-server authentication attempt *times* exceed { lock | lock-time *minutes* | unlock }**

**Parameter Description**

| Parameter                       | Description                                                                                                                                                    |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>times</i>                    | The maximum number of continuous SNMP authentication failures. The range is from 1 to 10.                                                                      |
| <b>exceed</b>                   | Indicates the action policy in the case that the maximum number of continuous SNMP authentication failures is exceeded.                                        |
| <b>lock</b>                     | Indicates that the source IP address is permanently locked to be authenticated and can be unlocked only by the administrator's manual configuration.           |
| <b>lock-time <i>minutes</i></b> | Indicates that the source IP address is locked for a period of time. The <i>minutes</i> indicates the lock time, ranging from 1 to 65,535. The unit is minute. |
| <b>unlock</b>                   | Indicates that no action policy is configured for the authentication failed user, that is, the SNMP authentication for this user is allowed.                   |

- Defaults** SNMP attack prevention is disabled by default.
- Command mode** Global configuration mode
- Usage Guide** The IP address of the SNMP authentication failed user is added to the blacklist. When the maximum number of continuous SNMP authentication failures is exceeded, the system will perform the related authentication limit actions according the configured policy.:
1. For the permanently locked IP addresses: The source IP addresses can be authenticated only after the administrator unlock them manually.
  2. For the IP addresses locked for a period time: The source IP addresses can be authenticated only after the lock time expires or the administrator unlock them manually.
  3. For the unlocked IP addresses: The source IP address can pass the authentication as long as the correct community (for SNMPv1 and SNMPv2) or username (for SNMPv3) is used.

**Configuration Examples** The following example configures the maximum number of continuous SNMP authentication failures to 4, and sets the IP address lock time to 30 seconds.

```
Ruijie(config)# snmp-server authentication attempt 4 exceed lock-time 30
```

| Related Commands | Command | Description |

## 1.6 snmp-server chassis-id

Use this command to specify the SNMP chassis ID. Use the **no** form of this command to restore the default chassis ID.

**snmp-server chassis-id text**

**no snmp-server chassis-id**

| Parameter Description | Parameter   | Description |
|-----------------------|-------------|-------------|
|                       | <i>text</i> |             |

**Defaults** The default is 60FF60.

**Command mode** Global configuration mode.

**Usage Guide** The SNMP chassis ID is generally the serial number of the device to facilitate identification. The SNMP chassis ID can be displayed through the **show snmp** command.

**Configuration** The following example specifies the SNMP chassis ID as 123456:

**Examples** Ruijie(config)# **snmp-server chassis-id** 123456

| Related Commands | Command | Description      |

**Description**

## 1.7 snmp-server community

Use this command to specify the SNMP community access string. Use the **no** form of this command to remove the SNMP community access string.

**snmp-server community** [ 0 | 7 ] *string* [ **view** *view-name* ] [ [ **ro** | **rw** ] [ **host** *ipaddr* ] [ **ipv6** *ipv6-aclname* ] [ *aclnum* ] [ *aclname* ]  
**no snmp-server community** [ 0 | 7 ] *string*

| Parameter Description | Parameter           | Description                                                                                                               |
|-----------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------|
|                       |                     | 0                                                                                                                         |
|                       | 7                   | Indicates that the community string is in ciphertext.                                                                     |
|                       | <i>string</i>       | Community string, which is the communication password between the NMS and the SNMP agent                                  |
|                       | <i>view-name</i>    | View name                                                                                                                 |
|                       | <b>ro</b>           | Indicates that the NMS can only read the variables of the MIB.                                                            |
|                       | <b>rw</b>           | Indicates that the NMS can read and write the variables of the MIB.                                                       |
|                       | <i>aclnum</i>       | Access list number (1 to 199, and 1300 to 2699), which specifies the IPV4 addresses that are permitted to access the MIB. |
|                       | <i>aclname</i>      | Access list name, which specifies the IPV4 addresses that are permitted to access the MIB.                                |
|                       | <i>ipv6-aclname</i> | IPv6 access list name, which specifies the IPv6 addresses that are permitted to access the MIB.                           |
|                       | <i>ipaddr</i>       | Specifies the IP address of the NMS to access the MIB.                                                                    |

**Defaults** All communities are read only by default.

**Command mode** Global configuration mode.

**Usage Guide** This command is an essential command to enable the SNMP agent function, such as specifying the community attribute and IP addresses of NMS to access the MIB.

To disable the SNMP agent function, use the **no snmp-server** command.

**Configuration Examples** The following example defines a SNMP community access string named public, which can be read-only.

```
Ruijie(config)# snmp-server community public ro
```

| Related Commands | Command | Description        |
|------------------|---------|--------------------|
|                  |         | <b>access-list</b> |

**Platform Description** N/A

## 1.8 snmp-server contact

Use this command to specify the system contact string. Use the **no** form of this command to remove the system contact string.

**snmp-server contact text**

**no snmp-server contact**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | <i>text</i> |

**Defaults** No system contact string is set by default.

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example specifies the SNMP system contract i-net800@i-net.com.cn:

```
Ruijie(config)# snmp-server contact i-net800@i-net.com.cn
```

| Related Commands | Command                 | Description                       |
|------------------|-------------------------|-----------------------------------|
|                  | <b>show snmp-server</b> | Displays the SNMP configuration.  |
|                  | <b>no snmp-server</b>   | Disables the SNMP agent function. |

**Platform Description** N/A

## 1.9 snmp-server enable secret-dictionary-check

Use this command to enable the secret dictionary check for the **community** and **user** fields. Use the **no** form of this command to disable the secret dictionary check.

**snmp-server enable secret-dictionary-check**

**no snmp-server enable secret-dictionary-check**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** Secret dictionary check for the **community** and **user** fields is disabled by default.

**Command mode** Global configuration mode.

**Usage Guide** This command must be used together with the **password policy** command.

**Configuration** The following example enables the secret dictionary check for the **community** field.

### Examples

```
Ruijie(config)# password policy min-size 6
Ruijie(config)# snmp-server enable secret-dictionary-check
Ruijie(config)#snmp-server community abc12
% The community(abc12) is a weak community!
```

| Related Commands | Command                 | Description                                            |
|------------------|-------------------------|--------------------------------------------------------|
|                  | <b>snmp-server host</b> | Specifies the SNMP host to send the SNMP trap message. |

**Platform** N/A  
**Description**

## 1.10 snmp-server enable traps

Use this command to enable the SNMP agent to send the SNMP trap message to NMS. Use the **no** form of this command to disable the SNMP agent to send the SNMP trap message to NMS.

**snmp-server enable traps [ notification-type ]**

**no snmp-server enable traps**

| Parameter Description | Parameter                | Description                                                     |
|-----------------------|--------------------------|-----------------------------------------------------------------|
|                       | <i>notification-type</i> | Specifies the type of trap messages.<br>snmp: SNMP trap message |

|  |                                                                                                                                                                                                                                                             |
|--|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | bgp: BGP trap message.<br>bridge: Bridge trap message.<br>isis: ISIS trap message.<br>mac-notification: MAC trap message.<br>ospf: OSPF trap message.<br>urpf: uRPF trap message.<br>vrrp: VRRP trap message.<br>web-auth: Web authentication trap message. |
|--|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Defaults** Sending trap message to the NMS is disabled by default.

**Command mode** Global configuration mode.

**Usage Guide** This command must be used together with the **snmp-server host** command to send the trap message. Specifying no trap type indicates all trap messages are sent.

**Configuration** The following example enables the SNMP agent to send the SNMP trap message.

**Examples**

```
Ruijie(config)# snmp-server enable traps snmp
Ruijie(config)# snmp-server host 192.168.12.219 public snmp
```

## 1.12 snmp-server group

Use this command to configure a new SNMP group. Use the **no** form of this command to remove a specified SNMP group.

```
snmp-server group groupname { v1 | v2c | v3 { auth | noauth | priv } } [ read readview ] [ write writeview ] [ access { [ ipv6 ipv6_aclname | aclnum | aclname } ]
no snmp-server group groupname { v1 | v2c | v3 { auth | noauth | priv } }
```

**Parameter  
Description**

| Parameter                          | Description                                                                                                             |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>v1</b>   <b>v2c</b>   <b>v3</b> | Specifies the SNMP version                                                                                              |
| <b>auth</b>                        | Specifies authentication of a packet without encrypting it. This applies to SNMPv3 only.                                |
| <b>noauth</b>                      | Specifies no authentication a packet. This applies to SNMPv3 only.                                                      |
| <b>priv</b>                        | Specifies authentication of a packet with encryption. This applies to SNMPv3 only.                                      |
| <i>readview</i>                    | Specifies a read-only view for the SNMP group. This view enables you to view only the contents of the agent.            |
| <i>writeview</i>                   | Specifies a write view for the SNMP group. This view enables you to enter data and configure the contents of the agent. |
| <i>aclnum</i>                      | Access list number, which specifies the IPV4 addresses that are permitted to access the MIB.                            |
| <i>aclname</i>                     | Name of the access list, which specifies the IPV4 addresses that are permitted to access the MIB.                       |
| <i>ipv6_aclname</i>                | Name of the IPv6 access list, which specifies the IPv6 addresses that are permitted to access the MIB.                  |

**Defaults** No SNMP groups are configured by default.

**Command** Global configuration mode.  
**mode**

**Usage Guide** N/A

**Configuration** The following example configures a new SNMP group.

**Examples**

```
Ruijie(config)# snmp-server group mib2user v3 priv read mib2
```

## 1.13 snmp-server host

Use this command to specify the SNMP host (NMS) to send the trap message. Use the **no** form of this command to remove the specified SNMP host.

**snmp-server host** [ **oob** ] { *host-addr* | **ipv6** *ipv6-addr* } [ **vrf** *vrfname* ] [ **traps** | **informs** ] [ **version** { **1** | **2c** | **3** [ **auth** | **noauth** | **priv** ] ] *community-string* [ **udp-port** *port-num* ] [ **via** *mgmt-name* ] [ *notification-type* ]

**no snmp-server host** [ **oob** ] { *host-addr* | **ipv6** *ipv6-addr* } [ **vrf** *vrfname* ] [ **traps** | **informs** ] [ **version** { **1** | **2c** | **3** { **auth** | **noauth** | **priv** } ] *community-string* [ **udp-port** *port-num* ] [ **via** *mgmt-name* ]

**Parameter  
Description**

| Parameter                                 | Description                                                                                                                                                                                           |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>oob</b>                                | Indicates the out of band communication, that is, the trap messages are sent to the alarm server through the MGMT port. This option is available only when the device is equipped with the MGMT port. |
| <i>host-addr</i>                          | SNMP host address                                                                                                                                                                                     |
| <i>ipv6-addr</i>                          | SNMP host address(ipv6)                                                                                                                                                                               |
| <i>vrfname</i>                            | Set the name of vrf forwarding table                                                                                                                                                                  |
| <b>trap</b>   <b>informs</b>              | Enables the host to send the SNMP notification as traps or informs.                                                                                                                                   |
| <b>version</b>                            | SNMP version: V1, V2C or V3                                                                                                                                                                           |
| <b>auth</b>   <b>noauth</b>   <b>priv</b> | Security level of SNMPv3 users                                                                                                                                                                        |
| <i>community-string</i>                   | Community string or username (SNMPv3 version)                                                                                                                                                         |
| <i>port-num</i>                           | Port of the SNMP host                                                                                                                                                                                 |
| <b>via</b> <i>mgmt-name</i>               | Specifies the MGMT port.                                                                                                                                                                              |
| <i>notification-type</i>                  | The type of the SNMP trap message, such as <b>snmp</b> .<br>If no type of the SNMP trap message is specified, all types of the SNMP trap message will be included.                                    |

**Defaults** No SNMP host is specified by default.

**Command mode** Global configuration mode.

**Usage Guide** This command must be used together with the **snmp-server enable traps** command to send the SNMP trap messages to NMS.

Multiple SNMP hosts can be configured to receive the SNMP trap messages. One host can use different combinations of the types of the SNMP trap message, but the last configuration for the same host will overwrite the previous configurations. In other words, to send different SNMP trap messages to the same host, different combination of SNMP trap messages can be configured.

The **via** parameter can take effect only when the **oob** parameter is configured.

The **vrf** parameter cannot be used together with the **oob** parameter.

**Configuration** The following example specifies an SNMP host to receive the SNMP event trap:

**Examples** Ruijie(config)# **snmp-server host 192.168.12.219 public snmp**

**Related Commands**

| Command                         | Description                                           |
|---------------------------------|-------------------------------------------------------|
| <b>snmp-server enable traps</b> | Enables the SNMP agent to send the SNMP trap message. |

**Platform** N/A

**Description**

## 1.14 snmp-server inform

Use this command to configure the resend times for inform requests and the inform request timeout. Use the **no** form of this command to restore the default settings.

**snmp-server inform [ retries *retry-time* | timeout *time* ]**

**no snmp-server inform**

**Parameter Description**

| Parameter        | Description                                                            |
|------------------|------------------------------------------------------------------------|
| <i>retry-num</i> | Specifies the resend times for inform requests, ranging from 0 to 255. |
| <i>time</i>      | Specifies the inform request timeout, ranging from 0 to 21,474,836.    |

**Defaults** The default *retry-num* is 3, and the default **timeout** *time* is 15 seconds.

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example configures the resend times of inform requests to 5.

**Examples**

```
Ruijie(config)# snmp-server inform retries 5
```

The following example configures the inform request timeout to 20 seconds.

```
Ruijie(config)# snmp-server inform timeout 20
```

**Description**

## 1.15 snmp-server location

Use this command to set the system location string. Use the **no** form of this command to remove the system location string.

**snmp-server location** *text*

**no snmp-server location**

**Parameter  
Description**

| Parameter   | Description                                            |
|-------------|--------------------------------------------------------|
| <i>text</i> | String that describes the system location information. |

**Defaults** No system location string is set by default.

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets the system location information:

**Examples**

```
Ruijie(config)# snmp-server location start-technology-city 4F of A Buliding
```

**Related  
Commands**

| Command                    | Description                          |
|----------------------------|--------------------------------------|
| <b>snmp-server contact</b> | Sets the system contact information. |

**Platform** N/A

**Description**

## 1.16 snmp-server logging

Use this command to enable the system to log the GET, GET-NETX and SET operations of NMS.

Use the **no** form of this command to disable the SNMP logging function.

**snmp-server logging { get-operation | set-operation }**

**no snmp-server logging { get-operation | set-operation }**

| Parameter Description | Parameter            | Description                                           |
|-----------------------|----------------------|-------------------------------------------------------|
|                       | <b>get-operation</b> | Logging function for the GET and GET-NEXT operations. |
|                       | <b>set-operation</b> | Logging function for the SET operation.               |

**Defaults** The SNMP logging function is disabled by default.

**Command mode** Global configuration mode.

**Usage Guide** This command is used to enable the logging function for the GET, GET-NETX and SET operations of NMS.

With the **get-operation** enabled, the SNMP agent logs the IP address of NMS, operation type and operation node OID during the GET and GET-NEXT operations.

With the **set-operation** enabled, the SNMP agent logs the IP address of NMS, operation type and operation node OID and related values during the SET operation.

A larger number of logs may affect the device performance. Under normal condition, it is recommended to disable the SNMP logging function.

**Configuration Examples** The following example enables the logging function for the GET and SET operations:

```
Ruijie(config)#snmp-server logging get-operation
Ruijie(config)#snmp-server logging set-operation
```

The operation logs are displayed as below:

```
Ruijie#*Feb 7 15:31:16: %SNMP-6-GET_OPER: NMS source-ip(13.12.11.7)
operation(GET) object(id=1.3.6.1.2.1.1.5.0)
```

```
Ruijie#*Feb 7 15:32:16:%SNMP-6-GETN_OPER: NMS source-ip(13.12.11.7)
operation(GET-NEXT) object(id=1.3.6.1.2.1.1.5.0)
```

```
Ruijie#*Feb 7 15:33:23: %SNMP-6-SET_OPER: NMS source-ip(13.12.11.7)
operation(SET) object(id=1.3.6.1.2.1.1.5.0, value=ruijie)
```

The following example disables the logging function for the GET and SET operations:

```
Ruijie(config)#no snmp-server logging get-operation
Ruijie(config)#no snmp-server logging set-operation
```

## 1.17 snmp-server net-id

Use this command to configure the network element coding information of the device. Use the **no** form of this command to remove the network element coding information.

**snmp-server net-id** *text*

**no snmp-server net-id**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       |           | <i>text</i> |

**Defaults** No network element coding information is configured by default.

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example configures the network element coding text to FZ\_CDMA\_MSC1.

**Examples**

```
Ruijie(config)# snmp-server net-id FZ_CDMA_MSC1
```

## 1.18 snmp-server packetsize

Use this command to specify the largest size of the SNMP packet. Use the **no** form of this command to restore the default value.

**snmp-server packetsize** *byte-count*

**no snmp-server packetsize**

**Parameter  
Description**

| Parameter         | Description                                        |
|-------------------|----------------------------------------------------|
| <i>byte-count</i> | Packet size. The range is from 484 to 17,876 bytes |

**Defaults** The default is 1,472 bytes.

**Command mode** Global configuration mode.

**Usage Guide** The following example specifies the largest size of SNMP packet as 1,492 bytes:

```
Ruijie(config)# snmp-server packetsize 1492
```

**Configuration Examples** N/A

**Related  
Commands**

| Command                         | Description                                                        |
|---------------------------------|--------------------------------------------------------------------|
| <b>snmp-server queue-length</b> | Specifies the length of the message queue for each SNMP trap host. |

**Platform  
Description** N/A

## 1.19 snmp-server queue-length

Use this command to specify the length of the message queue for each SNMP trap host. Use the **no** form of this command to restore the default value.

**snmp-server queue-length** *length*

**no snmp-server queue-length**

**Parameter  
Description**

| Parameter     | Description                                |
|---------------|--------------------------------------------|
| <i>length</i> | Queue length. The range is from 1 to 1000. |

**Defaults** The default is 10.

**Command mode** Global configuration mode.

**Usage Guide** Use this command to adjust the length of message queue for each SNMP trap host for the purposes of controlling the speed of sending the SNMP trap messages.

**Configuration** The following example specifies the length of message queue as 100.

**Examples**

```
Ruijie(config)# snmp-server queue-length 100
```

**Related  
Commands**

| Command                             | Description                                    |
|-------------------------------------|------------------------------------------------|
| <code>snmp-server packetsize</code> | Specifies the largest size of the SNMP packet. |

**Platform** N/A

**Description**

## 1.20 snmp-server system-shutdown

Use this command to enable the SNMP message reload function. Use the **no** form of this command to disable the SNMP message reload function.

**snmp-server system-shutdown**

**no snmp-server system-shutdown**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** The SNMP message reload function is disabled by default.

**Command  
mode** Global configuration mode.

**Usage Guide** Use this command to enable the SNMP message reload function which may enable the system to send the device reload traps to the NMS before the device is reloaded or rebooted.

**Configuration** The following example enables the SNMP message reload function:

**Examples**

```
Ruijie(config)# snmp-server system-shutdown
```

**Description**

## 1.21 snmp-server trap-format private

Use this command to configure the SNMP traps with private fields. Use the **no** form of this command to restore the default trap format.

**snmp-server trap-format private**  
**no snmp-server trap-format private**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

The private field is not carried in the SNMP trap by default.

**Command  
mode**

Global configuration mode.

**Usage Guide**

Use this command to configure the SNMP trap format with the private field. Currently, the supported data in the private field is alarm occurrence time. For the specific data type and range of each field, refer to RUIJIE-TRAP-FORMAT-MIB.mib file.

This command does not work if the traps are sent with SNMPv1.

**Configuration**

The following example configures the SNMP trap format with the private field.

**Examples**

```
Ruijie(config)# snmp-server trap-format private
```

**Description**

## 1.22 snmp-server trap-source

Use this command to specify the source interface of the SNMP trap message. Use the **no** form of this command to restore the default value.

**snmp-server trap-source interface**  
**no snmp-server trap-source**

**Parameter  
Description**

| Parameter        | Description                                               |
|------------------|-----------------------------------------------------------|
| <i>interface</i> | Specifies the source interface of the SNMP trap messages. |

**Defaults**

By default, the IP address of the interface from which the SNMP packet is sent is just the source address.

**Command**

Global configuration mode.

**mode**

**Usage Guide** For easy management and identification, you can use this command to fix a local IP address as the SNMP source address.

**Configuration Examples** The following example specifies the IP address of Ethernet interface 0/1 as the source address of the SNMP trap message:

```
Ruijie(config)# snmp-server trap-source fastethernet 0/1
```

**Related Commands**

| Command                         | Description                                                    |
|---------------------------------|----------------------------------------------------------------|
| <b>snmp-server enable traps</b> | Enables t the SNMP agent to send the SNMP trap message to NMS. |
| <b>snmp-server host</b>         | Specifies the NMS host to send the SNMP trap message.          |

**Platform** N/A

**Description**

## 1.23 snmp-server trap-timeout

Use this command to define the retransmission timeout time of the SNMP trap message. Use the **no** form of this command to restore the default value.

**snmp-server trap-timeout** *seconds*

**no snmp-server trap-timeout**

**Parameter Description**

| Parameter      | Description                                                                              |
|----------------|------------------------------------------------------------------------------------------|
| <i>seconds</i> | Timeout ( in seconds) of retransmit the SNMP trap message. The range is from 1 to 1,000. |

**Defaults** The default is 30 seconds.

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example specifies the timeout period as 60 seconds.

```
Ruijie(config)# snmp-server trap-timeout 60
```

**Related Commands**

| Command                         | Description                                   |
|---------------------------------|-----------------------------------------------|
| <b>snmp-server queue-length</b> | Specifies the length of message queue for the |

|                                |                                                        |
|--------------------------------|--------------------------------------------------------|
|                                | SNMP trap host.                                        |
| <b>snmp-server host</b>        | Specifies the NMS host to send the SNMP trap message.  |
| <b>snmp-server trap-source</b> | Specifies the source address of the SNMP trap message. |

**Platform** N/A

**Description**

## 1.24 snmp-server udp-port

Use this command to specify a port to receive SNMP packets. Use the **no** form of this command to restore the default setting.

**snmp-server udp port** *port-number*

**no snmp-server udp port**

**Parameter  
Description**

| Parameter          | Description                                   |
|--------------------|-----------------------------------------------|
| <i>port-number</i> | Specifies a port to receive the SNMP packets. |

**Defaults** The default is 161.

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example specifies port 15000 to receive the SNMP packets.

```
Ruijie(config)# snmp-server udp-port 15000
```

**Related  
Commands**

## Description

## 1.25 snmp-server user

Use this command to configure a new user to an SNMP group. Use the **no** form of this command to remove a user from an SNMP group.

```
snmp-server user username groupname { v1 | v2c | v3 [ encrypted ] [ auth { md5 | sha }
auth-password ] [ priv des56 priv-password ] } [ access { [ ipv6 ipv6_aclname ] [ aclnum |
aclname } ] ]
```

```
no snmp-server user username groupname { v1 | v2c | v3 }
```

Parameter  
Description

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>username</i>                    | Name of the user on the host that connects to the agent.                                                                                                                                                                                                                                                                                                             |
| <i>groupname</i>                   | Name of the group to which the user belongs.                                                                                                                                                                                                                                                                                                                         |
| <b>v1</b>   <b>v2c</b>   <b>v3</b> | Specifies the SNMP version. But only SNMPv3 supports the following security parameters.                                                                                                                                                                                                                                                                              |
| <b>encrypted</b>                   | Specifies whether the password appears in cipher text. In cipher text format, you need to enter continuous hexadecimal numeric characters. Note that the authentication password of MD5 has a length of 16 bytes, while that of SHA has a length of 20 bytes. Two characters make a byte. The encrypted key can be used only by the local SNMP engine on the switch. |
| <b>auth</b>                        | Specifies which authentication level should be used.                                                                                                                                                                                                                                                                                                                 |
| <i>auth-password</i>               | Password string (no more than 32 characters) used by the authentication protocol. The system will change the password to the corresponding authentication key.                                                                                                                                                                                                       |
| <b>priv</b>                        | Encryption mode. <i>des56</i> refers to 56-bit DES encryption protocol. <i>priv-password</i> : password string (no more than 32 characters) used for encryption. The system will change the password to the corresponding encryption key.                                                                                                                            |
| <b>md5</b>                         | Enables the MD5 authentication protocol. While the <b>sha</b> enables the SHA authentication protocol.                                                                                                                                                                                                                                                               |
| <i>aclnumber</i>                   | Access list number, which specifies the IPV4 addresses that are permitted to access the MIB.                                                                                                                                                                                                                                                                         |
| <i>aclname</i>                     | Name of the access list, which specifies the IPV4 addresses that are permitted to access the MIB.                                                                                                                                                                                                                                                                    |
| <i>ipv6_aclname</i>                | Name of the IPv6 access list, which specifies the IPv6 addresses that are permitted to access the MIB.                                                                                                                                                                                                                                                               |

## Defaults

N/A

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example configures an SNMPv3 user with MD5 authentication and DES encryption:

**Examples**

```
Ruijie(config)# snmp-server user user-2 mib2user v3 auth md5 authpassstr priv
des56 despassstr
```

**Related Commands**

| Command               | Description                           |
|-----------------------|---------------------------------------|
| <b>show snmp user</b> | Displays the SNMP user configuration. |

**Platform** N/A

**Description**

## 1.26 snmp-server view

Use this command to configure an SNMP view. Use the **no** form of this command to remove an SNMP view.

**snmp-server view** *view-name* *oid-tree* { **include** | **exclude** }

**no snmp-server view** *view-name* [ *oid-tree* ]

**Parameter Description**

| Parameter        | Description                                             |
|------------------|---------------------------------------------------------|
| <i>view-name</i> | View name                                               |
| <i>oid-tree</i>  | Specifies the MIB object to associate with the view.    |
| <b>include</b>   | Includes the sub trees of the MIB object in the view.   |
| <b>exclude</b>   | Excludes the sub trees of the MIB object from the view. |

**Defaults** By default, a view is set to access all MIB objects.

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example sets a view that includes all MIB-2 sub-trees (oid is 1.3.6.1).

**Examples**

```
Ruijie(config)# snmp-server view mib2 1.3.6.1 include
```

## 2 RMON Commands

### 2.1 rmon alarm

Use this command to monitor a MIB variable. Use the **no** form of this command to remove the alarm entry.

**rmon alarm** *number variable interval* {**absolute** | **delta** } **rising-threshold** *value* [*event-number*]  
**falling-threshold** *value* [*event-number*] [**owner** *ownername*]

**no rmon alarm** *number*

#### Parameter description

| Parameter                                | Description                                                                                                                                                                                                      |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>number</i>                            | Alarm number. The value ranges from 1-65,535.                                                                                                                                                                    |
| <i>variable</i>                          | Alarm variable. The value is a character string consisting of 1 to 255 characters in OID dotted format (the format is entry.integer.instance or a leaf node named .instance, for example. 1.3.6.1.2.1.2.1.10.1). |
| <i>interval</i>                          | Sampling interval. The value ranges from 1 to 2,147,483,647 in the unit of second.                                                                                                                               |
| <b>absolute</b>                          | Absolute sampling. In this mode, when the sampling time arrives, the system directly invokes the variable value.                                                                                                 |
| <b>delta</b>                             | Delta sampling. In this mode, when the sampling time arrives, the system invokes the delta value of the variable within the sampling interval.                                                                   |
| <b>rising-threshold</b><br><i>value</i>  | Rising threshold and the corresponding event number when the threshold is reached. The threshold ranges from -2,147,483,648 to +2,147,483,647.                                                                   |
| <i>event-number</i>                      | The event number ranges from 1 to 65,535.                                                                                                                                                                        |
| <b>falling-threshold</b><br><i>value</i> | Falling threshold and the corresponding event number when the threshold is reached. The threshold ranges from -2,147,483,648 to +2,147,483,647.                                                                  |
| <b>owner</b><br><i>ownername</i>         | Owner of an entry. The value is a character string consisting of 1 to 63 characters that are case sensitive.                                                                                                     |

**Default** N/A.

**Command mode** Global configuration mode.

#### Usage guidelines

The RGOS allows you to modify the configured history information of the Ethernet network, including variable, absolute/delta, owner, rising-threshold/falling-threshold, and the corresponding events. However, the modification does not take effect immediately until the system triggers the monitoring event at the next time.

#### Examples

The example below monitors the MIB variable instance ifInNUcastPkts.6.

```
Ruijie(config)# rmon alarm 10 1.3.6.1.2.1.2.2.1.12.6 30 delta
```

```
rising-threshold 20 1 falling-threshold 10 1 owner zhangsan
```

**Related commands**

| Command                                                                                                                                                  | Description               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| <b>rmon event</b> <i>number</i> [ <b>log</b> ] [ <b>trap</b> <i>community</i> ]<br><b>description</b> <i>string</i> [ <b>owner</b> <i>owner-string</i> ] | Adds an event definition. |

## 2.2 rmon collection history

Use this command to enable history statistics on the Ethernet interface. Use the **no** form of this command to remove the history entry.

**rmon collection history** *index* [**owner** *ownername*] [**buckets** *bucket-number*] [**interval** *seconds*]

**no rmon collection history** *index*

**Parameter description**

| Parameter                              | Description                                                                                                                               |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <i>index</i>                           | Index of a history entry. The value ranges from 1 to 65,535.                                                                              |
| <b>owner</b><br><i>ownername</i>       | Owner of an entry. The value is a character string consisting of 1 to 63 characters that are case sensitive.                              |
| <b>buckets</b><br><i>bucket-number</i> | Capacity of a history entry (that is, the maximum number of history entries). The value ranges from 1 to 65,535. The default value is 10. |
| <b>interval</b><br><i>seconds</i>      | Statistics period. The unit is second. The value ranges from 1 to 3,600. The default value is 1,800 seconds.                              |

**Default** N/A.

**Command mode** Interface configuration mode.

**Usage guidelines** The configured history control entry parameters cannot be modified. And the history entry can be removed from the interface where the entry configured.

The example below enables log statistics on interface GigabitEthernet 0/1.

**Examples**

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-GigabitEthernet0/1)#rmon collection history 1 owner UserA
buckets 5 interval 60
```

**Related commands**

| Command                                                                         | Description                                         |
|---------------------------------------------------------------------------------|-----------------------------------------------------|
| <b>rmon collection stats</b> <i>index</i><br>[ <b>owner</b> <i>owner-name</i> ] | Adds a statistical entry on the Ethernet interface. |

## 2.3 rmon collection stats

Use this command to monitor an Ethernet interface. Use the **no** form of this command to remove the configuration.

**rmon collection stats** *index* [**owner** *owner-string*]

**no rmon collection stats** *index*

| Parameter description | Parameter                     | Description                                                                                                                            |
|-----------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>index</i>                  | Index of the statistic table. The value ranges from 1 to 65,535.                                                                       |
|                       | <b>owner</b> <i>ownername</i> | Owner of an entry. The value is a character string consisting of 1 to 63 characters that are case sensitive and do not contain spaces. |

**Default** N/A.

**Command mode** Interface configuration mode.

**Usage guidelines** N/A.

The example below enables monitoring the statistics of interface GigabitEthernet 0/1.

### Examples

```
Ruijie# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#interface gigabitEthernet 0/1
Ruijie(config-GigabitEthernet0/1)# rmon collection stats 1 owner UserA
```

### Related commands

| Command                                                                                                                                                      | Description                   |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| <b>rmon collection history</b> <i>index</i> [ <b>owner</b> <i>owner-name</i> ]<br>[ <b>buckets</b> <i>bucket-number</i> ] [ <b>interval</b> <i>seconds</i> ] | Adds a history control entry. |

## 2.4 rmon event

Use this command to define an event. Use the **no** form of this command to remove the event entry.

**rmon event** *number* [**log**] [**trap** *community*] [*description-string*] [**description** *description-string*] [**owner** *owner-name*]

**no rmon event** *number*

| Parameter description | Parameter                    | Description                                                                                                    |
|-----------------------|------------------------------|----------------------------------------------------------------------------------------------------------------|
|                       | <i>number</i>                | Event number. The value ranges from 1 to 65,535.                                                               |
|                       | <b>log</b>                   | (Optional) Log event. When a log event is triggered, the system records a log.                                 |
|                       | <b>trap</b> <i>community</i> | (Optional) Trap event. When a trap event is triggered, the system sends trap with the group named "community". |

|                                                 |                                                                                                                         |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>description</b><br><i>description-string</i> | (Optional) Description of the event. The value is a character string consisting of 1 to 127 characters.                 |
| <b>owner</b><br><i>owner-name</i>               | (Optional) Owner of an entry. The value is a character string consisting of 1 to 63 characters that are case sensitive. |

**Default** N/A.

**Command mode** Global configuration mode.

**Usage guidelines** N/A.

**Examples**

The example below defines the event actions: log event and send trap message.

```
Ruijie#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Ruijie(config)#rmon event 1 log trap public description "ifInNUcastPkts
is abnormal" owner UserA
```

|                         | Command                                                                                                                                                              | Description          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| <b>Related commands</b> | <b>rmon alarm</b> <i>number variable interval {absolute   delta } rising-threshold value [event-number] falling-threshold value [event-number] [owner ownername]</i> | Adds an alarm entry. |

## 2.5 show rmon

**Default** Use this command to display the RMON configuration.  
**show rmo**

**Default** N/A.

**Command mode** Privileged EXEC mode.

**Usage guidelines** N/A.

**Examples**

The example below displays the RMON configuration.

```
Ruijie#show rmon
ether statistic table:
    index = 1
    interface = GigabitEthernet 0/1
    owner = admin
    status = 0
    dropEvents = 61
    octets = 170647461
```

```
pkts = 580375
broadcastPkts = 2135
multiPkts = 3615
crcAlignErrors = 0
underSizePkts = 0
overSizePkts = 0
fragments = 0
jabbers = 0
collisions = 0
packets64Octets = 3254668
packets65To127Octets = 1833370
packets128To255Octets = 2098146
packets256To511Octets = 126716
packets512To1023Octets = 363621
packets1024To1518Octets = 1077865
```

rmon history control table:

```
index = 1
interface = GigabitEthernet 0/1
bucketsRequested = 5
bucketsGranted = 5
interval = 60
owner = UserA
stats = 1
```

rmon history table:

```
index = 1
sampleIndex = 2485
intervalStart = 7d:22h:56m:38s
dropEvents = 0
octets = 5840
pkts = 27
broadcastPkts = 0
multiPkts = 0
crcAlignErrors = 0
underSizePkts = 0
overSizePkts = 0
fragments = 0
jabbers = 0
collisions = 0
utilization = 0
```

rmon alarm table:

```
index: 1
interval: 60
```

```

oid = 1.3.6.1.2.1.2.2.1.12.6
sampleType: 2
alarmValue: 0
startupAlarm: 3
risingThreshold: 20
fallingThreshold: 10
risingEventIndex: 1
fallingEventIndex: 1
owner: UserA
status: 1

rmon event table:
    index = 1
    description = ifInNUcastPkts is abnormal
    type = 4
    community = public
    lastTimeSent = 0d:0h:0m:0s
    owner =UserA
    status = 1

rmon log table:
    eventIndex = 1
    index = 1
    logTime = 6 d:19 h:21 m:48 s
    logDescription = ifInNUcastPkts is abnormal
    
```

**Related commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

## 2.6 show rmon alarm

**Default** Use this command to display the RMON alarm table.

**show rmon alarm**

**Default** N/A.

**Command mode** Privileged EXEC mode.

**Usage guidelines** N/A.

The example below displays the RMON alarm table.

**Examples**

```

Ruijie#show rmon alarm
rmon alarm table:
    
```

```

index: 1
interval: 60
oid = 1.3.6.1.2.1.2.2.1.12.6
sampleType: 2
alarmValue: 0
startupAlarm: 3
risingThreshold: 20
fallingThreshold: 10
risingEventIndex: 1
fallingEventIndex: 1
owner: UserA
status: 1
    
```

**Related commands**

| Command                                                                                                                                                                                                                                              | Description          |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| <b>rmon alarm</b> <i>number variable</i><br><i>interval {absolute   delta }</i><br><b>rising-threshold</b> <i>value</i><br><i>[event-number]</i> <b>falling-threshold</b> <i>value</i><br><i>[event-number]</i> [ <b>owner</b><br><i>ownername</i> ] | Adds an alarm entry. |

## 2.7 show rmon event

Use this command to display the event configuration.

**show rmon event**

**Default** N/A.

**Command mode** Privileged EXEC mode.

**Usage guidelines** N/A.

The example below displays the event configuration.

**Examples**

```

Ruijie#show rmon event
rmon event table:
    index = 1
    description = ifInNUcastPkts is abnormal
    type = 4
    community = public
    lastTimeSent = 0d:0h:0m:0s
    owner =UserA
    status = 1
    
```

```
rmon log table:
    eventIndex = 1
    index = 1
    logTime = 6d:19h:21m:48s
    logDescription = ifInNUcastPkts is abnormal
```

**Related commands**

| Command                                                                                                                                                            | Description          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| <b>rmon event</b> <i>number</i> [ <b>log</b> ] [ <b>trap</b> <i>community</i> ] [ <b>description</b> <i>description-string</i> ] [ <b>owner</b> <i>ownername</i> ] | Adds an event entry. |

## 2.8 show rmon history

Use this command to display the history information.

**show rmon history**

**Default** N/A.

**Command mode** Privileged EXEC mode.

**Usage guidelines** N/A.

The example below displays the history information.

```
Ruijie#show rmon history
rmon history control table:
    index = 1
    interface = GigabitEthernet 0/1
    bucketsRequested = 5
    bucketsGranted = 5
    interval = 60
    owner = UserA
    stats = 1

rmon history table:
    index = 1
    sampleIndex = 2485
    intervalStart = 7d:22h:56m:38s
    dropEvents = 0
    octets = 5840
    pkts = 27
    broadcastPkts = 0
    multiPkts = 0
    crcAlignErrors = 0
    underSizePkts = 0
```

**Examples**

```

overSizePkts = 0
fragments = 0
jabbers = 0
collisions = 0
utilization = 0
    
```

**Related commands**

| Command                                                                                                                                                   | Description                   |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| <b>rmon collection history</b> <i>index</i><br>[owner <i>ownername</i> ] [ <b>buckets</b><br><i>bucket-number</i> ] [ <b>interval</b><br><i>seconds</i> ] | Adds a history control entry. |

## 2.9 show rmon statistics

Use this command to display the RMON statistics.

**show rmon statistics**

**Default**

N/A.

**Command mode**

Privileged EXEC mode.

**Usage guidelines**

The example below displays the RMON statistics.

**Examples**

```

Ruijie#show rmon statistics
ether statistic table:
    index = 1
    interface = GigabitEthernet 0/1
    owner = admin
    status = 0
    dropEvents = 61
    octets = 170647461
    pkts = 580375
    broadcastPkts = 2135
    multiPkts = 3615
    crcAlignErrors = 0
    underSizePkts = 0
    overSizePkts = 0
    fragments = 0
    jabbers = 0
    collisions = 0
    packets64Octets = 3254668
    packets65To127Octets = 1833370
    
```

```
packets128To255Octets = 2098146
packets256To511Octets = 126716
packets512To1023Octets = 363621
packets1024To1518Octets = 1077865
```

**Related  
commands**

| Command                                                                        | Description               |
|--------------------------------------------------------------------------------|---------------------------|
| <b>rmon collection stats</b> <i>index</i> [ <b>owner</b> <i>owner-string</i> ] | Adds a statistical entry. |

## 3 NTP Commands

### 3.1 no ntp

Use this command to disable Network Time Protocol (NTP), and clear all NTP configuration.

**no ntp**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** NTP is disabled by default.

**Command mode** Global configuration mode.

**Usage Guide** By default, NTP is disabled. However, once the NTP server or the NTP primary clock is configured, the NTP service will be enabled.

**Configuration Examples** The following example disables NTP.

```
Ruijie(config)#no ntp
```

| Related Commands | Command    | Description              |
|------------------|------------|--------------------------|
|                  | ntp server | Specifies an NTP server. |

**Platform Description** N/A

### 3.2 ntp access-group

Use this command to configure an access group to control NTP access. Use the **no** form of this command to remove the peer access group.

**ntp access-group** { **peer** | **serve** | **serve-only** | **query-only** } *access-list-number* | *access-list-name*  
**no ntp access-group** { **peer** | **serve** | **serve-only** | **query-only** } *access-list-number* | *access-list-name*

| Parameter Description | Parameter | Description                                                                                                                           |
|-----------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------|
|                       | peer      | Allows the device to receive time requests and NTP control queries to synchronize itself to the servers specified in the access list. |

|                           |                                                                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>serve</b>              | Allows the device to receive time requests and NTP control queries from the servers specified in the access list but not to synchronize itself to the specified servers. |
| <b>serve-only</b>         | Allows the device to receive only time requests from the servers specified in the access list.                                                                           |
| <b>query-only</b>         | Allows the device to receive only NTP control queries from servers specified in the access list.                                                                         |
| <i>access-list-number</i> | Access control list number, ranging from 1 to 99 and 1300 to 1999.                                                                                                       |
| <i>access-list-name</i>   | Access control list name.                                                                                                                                                |

**Defaults** No access rule to control NTP access is configured by default, namely, NTP access is granted to all devices.

**Command mode** Global configuration mode.

**Usage Guide** Use this command to configure an access group to control NTP access, providing a minimal security measures (more secure way is to use the NTP authentication mechanism).

The NTP service enables the access group options to be scanned in the following order, from least restrictive to most restrictive: **peer**, **serve**, **serve-only**, **query-only**.

If you do not configure any access groups, NTP access is granted to all devices. However, once you configure the access rule, NTP access is granted only to the devices specified in the access list.

 NTP control query is not supported in the current system. Although it matches with the order in accordance with the above rules, the related requests about the control and query are not supported.

**Configuration Examples** The following example shows how to allow the device to only receive time requests from the device of 192.168.1.1.

```
Ruijie(config)# access-list 1 permit 192.168.1.1
Ruijie(config)# ntp access-group serve-only 1
```

**Related Commands**

| Command               | Description                        |
|-----------------------|------------------------------------|
| <b>ip access-list</b> | Creates an IP access control list. |

**Platform** N/A  
**Description**

### 3.3 ntp authenticate

Use this command to enable NTP authentication. Use the **no** form of this command to disable NTP

authentication.

**ntp authenticate**

**no ntp authenticate**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** Disabled.

**Command mode** Global configuration mode.

**Usage Guide** If NTP authentication is disabled, the synchronization communication is not encrypted. To enable encrypted communication on the server, enable the NTP authentication and configure other keys globally.

NTP authentication is implemented through the trusted key specified by the **ntp authentication-key** and **ntp trusted-key** commands.

**Configuration Examples** After an authentication key is configured and specified as the global trusted key, enable NTP authentication.

```
Ruijie(config)#ntp authentication-key 6 md5 woooooop
Ruijie(config)#ntp trusted-key 6
Ruijie(config)#ntp authenticate
```

| Related Commands | Command                       | Description                         |
|------------------|-------------------------------|-------------------------------------|
|                  | <b>ntp authentication-key</b> | Sets the global authentication key. |
|                  | <b>ntp trusted-key</b>        | Configures the global trusted key.  |

**Platform Description** N/A

### 3.4 ntp authentication-key

Use this command to configure an NTP authentication key. Use the **no** form of this command to remove the NTP authentication key.

**ntp authentication-key** *key-id* **md5** *key-string* [*enc-type*]

**no ntp authentication-key** *key-id*

| Parameter Description | Parameter         | Description                           |
|-----------------------|-------------------|---------------------------------------|
|                       | <i>key-id</i>     | Key ID, ranging from 1 to 4294967295. |
|                       | <i>key-string</i> | Key string                            |

|                 |                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | An encrypted key supports up to 64 bytes of length, while a non-encrypted key supports up to 31 bytes.                                                               |
| <i>enc-type</i> | (Optional) Whether this key is encrypted, where, 0 indicates the key is not encrypted, 7 indicates the key is encrypted simply. The key is not encrypted by default. |

**Defaults** NTP authentication key is not configured by default.

**Command mode** Global configuration mode.

**Usage Guide** Use this command to configure an NTP authentication key and enables the **md5** algorithm for authentication. Each key presents a unique key ID, which can be configured as a trusted key using the **ntp trusted-key** command..

You can configure up to 1024 NTP authentication keys. However, each server can support only one key.

**Configuration** The following example configures an NTP authentication key.

**Examples**

```
Ruijie(config)#ntp authentication-key 6 md5 woooooop
```

**Related Commands**

| Command                 | Description                    |
|-------------------------|--------------------------------|
| <b>ntp authenticate</b> | Enables NTP authentication.    |
| <b>ntp trusted-key</b>  | Configures an NTP trusted key. |
| <b>ntp server</b>       | Specifies an NTP server.       |

**Platform** N/A

**Description**

### 3.5 ntp disable

Use this command to disable the device to receive NTP packets on the specified interface.

**ntp disable**

**Parameter Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** All NTP packets can be received by default.

**Command mode** Interface configuration mode.

**Usage Guide** The NTP message received on any interface can be provided to the client to carry out the clock

adjustment. The function can be set to shield the NTP message received from the corresponding interface.

By default, the device receives NTP packets on all interfaces, and adjust clock for the client. You can use this command to disable the device to receive NTP packets on the specified interface.

 This command is configured only the interface that can receive and send IP packets.

**Configuration** The following example disables the device to receive the NTP packets.

**Examples** Ruijie(config-if)# no ntp disable

**Related  
Commands**

| Command | Description |
|---------|-------------|
| N/A     | N/A         |

**Platform  
Description** N/A

### 3.6 ntp interval

Use this command to set the interval for time synchronization between the NTP client and the NTP server. Use the **no** form of this command to restore the default time synchronization interval.

**ntp interval** *seconds*

**no ntp interval**

**Parameter  
Description**

| Parameter      | Description                                                                               |
|----------------|-------------------------------------------------------------------------------------------|
| <i>seconds</i> | Sets the time synchronization interval in seconds. The value ranges from 10 to 2,592,000. |

**Defaults** The default value is 64.

**Command  
Mode** Global configuration mode

**Default Level** 14

**Usage Guide**

 The configuration does not take effect immediately. For immediate validation, enable NTP and then set the interval. If the NTP client has never synchronized the time successfully, it rapidly synchronizes the time at an interval of 5s. Then, it synchronizes time at the preset interval after the first successful time synchronization.

**Configuration** The following example configures the NTP time synchronization interval to 3,600 seconds.

**Examples** Ruijie(config)# ntp interval 3600

## 3.7 ntp master

Use this command to configure the device to act as an authoritative NTP server, synchronizing time to other devices. Use the **no** form of this command to remove the device as an authoritative NTP server.

**ntp master** [ *stratum* ]

**no ntp master**

| Parameter Description | Parameter      | Description                                                 |
|-----------------------|----------------|-------------------------------------------------------------|
|                       | <i>stratum</i> | Stratum level. The range is from 1 to 15. The default is 8. |

**Defaults** N/A

**Command mode** Global configuration mode.

**Usage Guide** In general, the local device synchronizes time from the external time source directly or indirectly. However, if the time synchronization fails due to network connection trouble, you can use this command to configure the local device to act as an authoritative NTP server to synchronize time to other devices. Once configured, the device will not perform time synchronization with the time source which is of a higher stratum.

 Configuring the device to act as an authoritative NTP server (in particular, specify a lower stratum level), may be likely to overwrite the effective time. If multiple devices in the same network are configured with this command, the time synchronization may be instable due to the time difference between the devices.

 Before configuring this command, you need to manually correct the system clock to avoid too much bias if the device has never performed time synchronization with the external clock source.

**Configuration Examples** The following example configures the device to act as an authoritative NTP server, and sets the stratum level to 12:

```
Ruijie(config)# ntp master 12
```

| Related Commands | Command | Description |

**Platform Description** N/A

### 3.8 ntp server

Use this command to specify a NTP server for the NTP client. Use the **no** form of this command to delete the specified NTP server.

```
ntp server [ oob | vrf vrf-name ] { ip-addr | domain | ip domain | ipv6 domain } [ version version ]
[ source if-name ] [ key keyid ] [ prefer ] [ via mgmt-name ]
no ntp server ip-addr
```

#### Parameter Description

| Parameter                  | Description                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>oob</b>                 | (Optional) Accesses the NTP server from the MGMT interface. By default, this option is disabled.                                               |
| <b>vrf</b> <i>vrf-name</i> | Specifies the virtual routing and forwarding (VRF) name. By default, this parameter is disabled.                                               |
| <i>ip-addr</i>             | Sets the IP address of the NTP server. The address can be in IPv4 or IPv6 format.                                                              |
| <i>domain</i>              | Sets the domain name of the NTP server, supporting IPv4 and IPv6.                                                                              |
| <i>version</i>             | (Optional) Specifies the NTP version (1-3). The default is NTPv3.                                                                              |
| <i>if-name</i>             | (Optional) Specifies the source interface from which the NTP message is sent (L3 interface).                                                   |
| <i>keyid</i>               | (Optional) Specifies the encryption key adopted when communication with the corresponding server. The key ID range is from 1 to 4,294,967,295. |
| <b>prefer</b>              | (Optional) Specifies the given NTP server as the preferred one.                                                                                |
| <i>mgmt-name</i>           | (Optional) Specifies the egress MGMT interface for the packets in oob mode.                                                                    |

**Defaults** No NTP server is configured by default.

**Command mode** Global configuration mode.

**Usage Guide** At present, RGOS system only supports clients other than servers. Up to 20 servers can be synchronized.

To carry out the encrypted communication with the server, set the global encryption key and global trusted key firstly, and then specify the corresponding key as the trusted key of the server to launch the encrypted communication of the server. It requires the server presents identical global encryption key and global trust key to complete the encrypted communication with the server.

In the same condition (for instance, precision), the prefer clock is used for synchronization.

 The source interface of NTP packets must be configured with the IP address and can be communicated with the peer.

**Configuration** The following example configures an NTP server.

**Examples** For IPv4: `Ruijie(config)# ntp server 192.168.210.222`  
 For IPv6: `Ruijie(config)# ntp server 10::2`

**Related  
Commands**

| Command             | Description   |
|---------------------|---------------|
| <code>no ntp</code> | Disables NTP. |

**Platform** N/A  
**Description**

### 3.9 ntp trusted-key

Use this command to set a global trusted key. Use the **no** form of this command to remove the global trusted key.

**ntp trusted-key** *key-id*  
**no ntp trusted-key** *key-id*

**Parameter  
Description**

| Parameter     | Description                                          |
|---------------|------------------------------------------------------|
| <i>key-id</i> | Global trusted key ID, ranging from 1 to 4294967295. |

**Defaults** N/A

**Command  
mode** Global configuration mode.

**Usage Guide** The NTP communication parties must use the same trusted key. The key is identified by ID and is not transmitted to improve security.

**Configuration** The following example configures an authentication key and sets it as a trusted key.

**Examples** `Ruijie(config)#ntp authentication-key 6 md5 woooooop`  
`Ruijie(config)#ntp trusted-key 6`  
`Ruijie(config)#ntp server 192.168.210.222 key 6`

|-------------------------------------|---------------------------------------|
| <code>ntp authenticate</code>       | Enables NTP authentication.           |
| <code>ntp authentication-key</code> | Configures an NTP authentication key. |
| <code>ntp server</code>             | Configures an NTP server.             |

**Platform** N/A  
**Description**

### 3.10 ntp update-calendar

Use this command to enable the NTP client to periodically update the device clock with the time synchronized from the external source clock. Use the **no** form of this command to remove this function.

**ntp update-calendar**

**no ntp update-calendar**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** By default, update the calendar periodically is not configured.

**Command mode** Global configuration mode.

**Usage Guide** By default, the NTP update-calendar is not configured. After configuration, the NTP client updates the calendar at the same time when the time synchronization of external time source is successful. It is recommended to enable this function for keeping the accurate calendar.

**Configuration** The following example configures the NTP update calendar periodically.

**Examples** Ruijie(config)# ntp update-calendar

| Related<br>Commands | Command | Description |

### 3.11 show ntp server

Use this command to display the NTP server configuration.

**show ntp server**

| Parameter<br>Description | Parameter | Description |
|--------------------------|-----------|-------------|
|                          |           | N/A         |

**Defaults** N/A

**Command** Privileged EXEC mode, global configuration mode, interface configuration mode, VLAN configuration

**mode** mode

**Usage Guide** N/A

**Configuration** The following example displays the NTP server.

**Examples**

```
Ruijie# show ntp server
ntp-server          source      keyid      prefer  version
-----
-----
10::2              None       None       FALSE   3
192.168.210.222   None       None       FALSE   3
```

## 3.12 show ntp status

Use this command to display the NTP configuration.

**show ntp status**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** N/A

**Command mode** Privileged EXEC mode, global configuration mode, interface configuration mode, VLAN configuration mode

**Usage Guide** Use this command to display the NTP configuration. No configuration is displayed before the synchronization server is configured for the first time.

**Configuration** The following example displays the NTP configuration.

**Examples**

```
Ruijie# show ntp status
Clock is synchronized, stratum 8, reference is 127.127.1.1
nominal freq is 250.0000 Hz, actual freq is 250.0000 Hz, precision is 2**24
reference time is D4BD819B.433892EE (01:27:55.000 UTC )
clock offset is 0.00000 sec, root delay is 0.00000 sec
root dispersion is 0.00002 msec, peer dispersion is 0.00002 msec
```

## 4 SNTP Commands

### 4.1 show sntp

Use this command to display the SNTP configuration.

**show sntp**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults**

**Command  
mode**

Privileged EXEC mode, global configuration mode, interface configuration mode.

**Usage Guide**

N/A

**Configuration**

The following example displays the SNTP configuration.

**Examples**

```
Ruijie# show sntp
SNTP state      : Enable
SNTP server     : 192.168.4.12
SNTP sync interval : 60
Time zone      : +8
```

**Related  
Commands**

| Command            | Description   |
|--------------------|---------------|
| <b>sntp enable</b> | Enables SNTP. |

**Platform**

N/A

**Description**

### 4.2 sntp enable

Use this command to enable the SNTP function. Use the **no** form of this command to restore the default value.

**sntp enable**

**no sntp enable**

**Parameter  
Description**

| Parameter | Description |
|-----------|-------------|
| N/A       | N/A         |

**Defaults** SNTP is disabled by default.

**Command mode** Global configuration mode.

**Usage Guide** N/A

**Configuration** The following example enables SNTP.

**Examples**

```
Ruijie(config)# sntp enable
```

**Related Commands**

| Command          | Description                      |
|------------------|----------------------------------|
| <b>show sntp</b> | Displays the SNTP configuration. |

**Platform Description** N/A

### 4.3 sntp interval

Use this command to set the interval for the SNTP client to synchronize its clock with the NTP/SNTP server. Use the **no** form of this command to restore the default synchronization interval.

**sntp interval** *seconds*

**no sntp interval**

**Parameter Description**

| Parameter      | Description                                                                       |
|----------------|-----------------------------------------------------------------------------------|
| <i>seconds</i> | Synchronization interval. The unit is second, and the range is from 60 to 65,535. |

**Defaults** The default synchronization interval is 1,800 seconds.

**Command mode** Global configuration mode.

**Usage Guide** To make the synchronization interval configuration effective, run the **sntp enable** command.

**Configuration** The following example configures the synchronization interval to 3,600 seconds.

**Examples**

```
Ruijie(config)# sntp interval 3600
```

**Related Commands**

| Command            | Description                      |
|--------------------|----------------------------------|
| <b>sntp enable</b> | Enables SNTP.                    |
| <b>show sntp</b>   | Displays the SNTP configuration. |

**Platform** N/A  
**Description**

## 4.4 sntp server

Use this command to specify an SNTP server. Use the **no** form of this command to remove the SNTP server.

**sntp server** [ **oob** ] { *ip-address* | *domain* } [ **via** *mgmt-name* ] [ **source** *source-ip-address* ]  
**no sntp server**

| Parameter Description | Parameter                | Description                                                                 |
|-----------------------|--------------------------|-----------------------------------------------------------------------------|
|                       | <i>ip-address</i>        | IP address of the SNTP server.                                              |
|                       | <b>oob</b>               | (Optional) Accesses the SNTP server from the MGMT interface.                |
|                       | <i>domain</i>            | Specifies the domain name of the SNTP server.                               |
|                       | <i>source-ip-address</i> | (Optional) Indicates the specified source IP address.                       |
|                       | <i>mgmt-name</i>         | (Optional) Specifies the egress MGMT interface for the packets in oob mode. |

**Defaults** No SNTP server is configured by default.

**Command mode** Global configuration mode.

**Usage Guide** As SNTP is fully compatible with NTP, the SNTP server can be used as an NTP server in Internet.

**Configuration** The following example specifies an SNTP server in Internet.

**Examples** Ruijie(config)# sntp server 192.168.4.12

| Related Commands | Command            | Description                      |

## 5 SPAN-RSPAN Commands

### 5.1 mac-loopback

Use this command to enable MAC loopback. Use the **no** form of this command to disable MAC loopback.

**mac-loopback**

**no mac-loopback**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** MAC loopback is disabled by default.

**Command mode** Interface configuration mode.

**Usage Guide** The MAC loopback feature must be enabled on the interfaces for purposes of local one-to-many mirroring. (Please enable the MAC loopback feature on the down interface, and do not add other configurations to the interface.)

**Configuration Examples** The following example configures a remote VLAN.

```
Ruijie(config)#vlan 100
Ruijie(config-vlan)#remote-span
Ruijie(config-vlan)#exit
```

The following example configures a session and specifies the mirrored port.

```
Ruijie(config)#monitor session 1 remote-source
Ruijie(config)#monitor session 1 source interface gigabitEthernet 4/1 both
```

The following example configures the mirroring port, and enables MAC loopback on the port.

```
Ruijie(config)#monitor session 1 destination remote vlan 100 interface
gigabitEthernet 4/2 switch
Ruijie(config)#interface gigabitEthernet 4/2
Ruijie(config-if-GigabitEthernet 4/2)#switchport access vlan 100
Ruijie(config-if-GigabitEthernet 4/2)#mac-loopback
```

The following example adds interfaces GigabitEthernet 4/3-4 to the remote VLAN.

```
Ruijie(config)#interface range gigabitEthernet 4/3-4
Ruijie(config-if-range)#switchport access vlan 100
```

| Related Commands | Command | Description |

**Platform** N/A  
**Description**

## 5.2 monitor session

Use this command to configure the SPAN session and specify the source port (monitored port).

**monitor session** *session-num* **source interface** *interface-id* [ **both** | **rx** | **tx** ]

Use this command to configure the SPAN session mirroring only the traffic permitted by the access list

**monitor session** *session-num* **source interface** *interface-id* **rx acl** *acl-name*

Use this command to configure the SPAN session and specify the destination port (monitoring port).

**monitor session** *session-num* **destination interface** *interface-id* [**switch** ]

Use this command to configure the SPAN session monitoring the CPU packets.

**monitor session** *session-num* **source interface** *interface-id* **tx cpu**

Use this command to configure the remote SPAN session ID on the source device..

**monitor session** *session-num* **remote-source**

Use this command to configure the remote SPAN session ID on the destination device.

**monitor session** *session-num* **remote-destination**

Use this command to configure the remote SPAN session and specify the remote SPAN destination VLAN.

**monitor session** *session-num* **destination remote vlan** *remote-vlan-id* **interface** *interface-id*  
 [ **switch** ]

Use this command to configure the SPAN session and specify the source VLAN to monitor. Note that the source VLAN should not be a remote VLAN.

**monitor session** *session-num* **source vlan** *vlan-id* [ **rx** ]

Use this command to limit the SPAN source traffic to specific VLANs.

**monitor session** *session-num* **filter vlan** *vlan-id-list*

Use this command to remove the specified SPAN session, or remove the source port or destination port of the specified SPAN session.

**no monitor session** *session-num* [ **source interface** *interface-id* | **destination interface**

*interface-id* ]

Use this command to remove the specified remote SPAN session, or remove the destination port of the remote SPAN session.

**no monitor session** *session-num* [ **destination remote vlan** *remote-vlan-id* **interface** *interface-id* ]

Use this command to remove the specified remote SPAN session, or remove the destination port of the remote SPAN session.

**default monitor session** *session-num* [ **destination remote vlan** *remote-vlan-id* **interface** *interface-id* ]

Use this command to remove the specified SPAN session, or remove the source port or destination port of the SPAN session.

**default monitor session** *session-num* { **source interface** *interface-id* | **destination interface** *interface-id* }

**Parameter  
Description**

| Parameter                  | Description                                                                           |
|----------------------------|---------------------------------------------------------------------------------------|
| <i>session_number</i>      | SPAN session number                                                                   |
| <i>interface-id</i>        | Interface name                                                                        |
| <b>acl</b> <i>acl-name</i> | Access list name                                                                      |
| <i>remote-vlan-id</i>      | Remote VLAN ID                                                                        |
| <i>vlan-id</i>             | VLAN ID (remote VLAN excluded)                                                        |
| <i>vlan-id-list</i>        | VLAN list (remote VLAN excluded)                                                      |
| <b>rx</b>                  | Monitors the only received traffic.                                                   |
| <b>tx</b>                  | Monitors the only transmitted traffic.                                                |
| <b>both</b>                | Monitors both received and transmitted traffic. This is the default.                  |
| <b>switch</b>              | Enables switching on the destination port. Switching function is disabled by default. |
| <b>cpu</b>                 | Monitors the CPU packets. This is disabled by default.                                |

**Defaults** Port monitoring is disabled by default.

**Command mode** Global configuration mode.

**Usage Guide** Use this command to configure SPAN or remote SPAN, and specify the source port or destination port.

If the **both**, **rx** or **tx** is not specified for the source port, the **both** parameter is the default.

Configuring an access list for the source port indicates that only the traffic permitted by the access list is monitored.

The **switch** feature is disabled on the destination port.

CPU packet monitoring, which is enabled through the **cpu** parameter, is disabled by default.

**Configuration** The following example configures the source port and destination port of the SPAN session.

**Examples**

```
Ruijie(config)# monitor session 1 source interface gigabitEthernet 0/1
Ruijie(config)# monitor session 1 destination interface gigabitEthernet 0/2
```

The following example configures the SPAN session mirroring only the traffic permitted by the access list.

```
Ruijie(config)# monitor session 3 source interface gigabitEthernet 0/3 rx acl
90
```

The following example configures a remote SPAN session.

```
Ruijie(config)# monitor session 10 remote-source
```

The following example configures the destination port of the remote SPAN session.

```
Ruijie(config)# monitor session 4 destination remote vlan 10 interface
gigabitEthernet 0/5
```

The following example configures the source VLAN of the SPAN session.

```
Ruijie(config)# monitor session 1 source vlan 1
```

The following example removes the SPAN session.

```
Ruijie(config)# no monitor session 1
```

The following example removes the source port and destination port of the SPAN session.

```
Ruijie(config)# no monitor session 1 source interface gigabitEthernet 0/18
Ruijie(config)# no monitor session 1 destination interface gigabitEthernet
0/18
```

The following example configures the SPAN session monitoring only the traffic sent from CPU.

```
Ruijie(config)# monitor session 3 source interface gigabitEthernet 0/3 tx cpu
```

The following example configures the SPAN session monitoring traffic, including the traffic sent from CPU.

```
Ruijie(config)# monitor session 3 source interface gigabitEthernet 0/3 tx cpu
Ruijie(config)# monitor session 3 source interface gigabitEthernet 0/3 tx
```

## 5.3 remote-span

Use this command to configure a remote SPAN VLAN in VLAN configuration mode. Use the **no** form of this command to disable the remote SPAN VLAN.

**remote-span**

**no remote-span**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|                       | N/A       | N/A         |

**Defaults** Remote SPAN VLAN is disabled by default.

**Command mode** VLAN configuration mode.

**Usage Guide** N/A

**Configuration Examples** The following example configures a remote SPAN VLAN.

```
Ruijie(config)# vlan 100
Ruijie(config-vlan)# remote-span
```

| Related Commands | Command          | Description                  |
|------------------|------------------|------------------------------|
|                  | <b>show vlan</b> | Displays VLAN configuration. |

**Platform Description** N/A

## 5.4 show monitor

Use this command to display the SPAN configurations.

**show monitor** [ **session** *session\_number* ]

| Parameter Description | Parameter             | Description                          |
|-----------------------|-----------------------|--------------------------------------|
|                       | <i>session_number</i> | Displays the specified SPAN session. |

**Defaults** N/A

**Command mode** Privileged EXEC mode, global configuration mode and interface configuration mode

**Usage Guide** N/A

**Configuration** This following example displays all SPAN sessions.

**Examples**

```
Ruijie(config)# show monitor
sess-num: 2
span-type: LOCAL_SPAN
src-intf:
TenGigabitEthernet 0/5      frame-type Both
dest-intf:
TenGigabitEthernet 0/6
sess-num: 1
span-type: LOCAL_SPAN
src-intf:
TenGigabitEthernet 0/3      frame-type Both
dest-intf:
```

The following example displays SPAN session 1.

```
Ruijie(config)# show monitor session 1
sess-num: 1
span-type: LOCAL_SPAN
src-intf:
TenGigabitEthernet 0/3      frame-type Both
dest-intf:
TenGigabitEthernet 0/4
```

## 6 sFlow Commands

### 6.1 sflow agent

Use this command to configure the address of the sFlow Agent.

```
sflow agent { address { ip-address | ipv6 ipv6-address } } | { interface { interface-name | ipv6 interface-name } }
```

Use this command to delete the address of the sFlow Agent.

```
no sflow agent { address | interface }
```

Use this command to restore the default setting.

```
default sflow agent { address | interface }
```

#### Parameter Description

| Parameter                         | Description                                   |
|-----------------------------------|-----------------------------------------------|
| <b>address</b>                    | Configures the IP address of the sFlow Agent. |
| <i>ip-address</i>                 | sFlow Agent IPv4 address.                     |
| <b>ipv6</b> <i>ipv6-address</i>   | sFlow Agent IPv6 address.                     |
| <b>interface</b>                  | Configures the interface of the sFlow Agent.  |
| <i>interface-name</i>             | Interface of IPv4 address.                    |
| <b>ipv6</b> <i>interface-name</i> | Interface of IPv6 address.                    |

#### Defaults

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** This command is used to configure the Agent IP address field in the output sFlow datagram. The datagram not configured with this field cannot be output. The sFlow Agent address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Agent address, a message indicating configuration failure is displayed. It is recommended that the IP address of the sFlow Agent device be configured as the sFlow Agent address.

**Configuration Examples** The following example configures 192.168.2.1 as the sFlow Agent address.

```
Examples Ruijie(config)# sflow agent address 192.168.2.1
```

**Verification** Use the show sflow command to display the sFlow configuration.

**Prompt** Prompt an error message when the address is invalid.

**Messages**      `invalid host address.`

**Common Errors**      N/A

**Platforms**      N/A

## 6.2 sflow collector *collector-id* destination

Use this command to configure the address of the sFlow Collector.

```
sflow collector collector-id destination { ip-address | ipv6 ipv6_address } udp-port [ vrf vrf-name ] |
[ description collector-name ]
```

Use this command to delete the address of the sFlow Collector.

```
no sflow collector collector-id destination { ip-address | ipv6 ipv6_address } udp-port [ vrf vrf-name ]
[ description collector-name ]
```

Use this command to delete the address of the sFlow Collector.

```
default sflow collector collector-id destination { ip-address | ipv6 ipv6_address } udp-port [ vrf
vrf-name ] | [ description collector-name ]
```

### Parameter Description

| Parameter                                | Description                                         |
|------------------------------------------|-----------------------------------------------------|
| <i>collector-id</i>                      | sFlow Collector ID. The range is from 1 to 2.       |
| <i>ip-address</i>                        | sFlow Collector IPv4 address                        |
| <b>ipv6</b> <i>ipv6-address</i>          | sFlow Collector IPv6 address                        |
| <i>udp-port</i>                          | sFlow Collector listening port number               |
| <b>vrf</b> <i>vrf-name</i>               | VRF instance name. It is not configured by default. |
| <b>description</b> <i>collector-name</i> | Description of the sFlow Collector.                 |

### Defaults

**Command**      Global configuration mode

**Mode**

**Default Level**      14

**Usage Guide**      This command is used to configure the sFlow Collector address. The sFlow Collector address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Collector address, a message indicating configuration failure is displayed. The sFlow Collector monitors the sFlow datagram on the specified port. When the vrf parameter is configured, the corresponding VRF instance must exist. When you remove the a VRF instance, the sFlow Collector address will be removed if this VRF instance is also configured for an sFlow Collector address.

**Configuration** The following example configures 192.168.1.100 as the address of sFlow Collector 1, 6343 as the port number and vpn 1 as the VRF instance.

**Examples**

```
Ruijie(config)# sflow collector 1 destination 192.168.2.100 6343 vrf vpn1
```

**Verification** Use the **show sflow** command to display the sFlow Collector.

**Prompt** Prompt an error message when the address is invalid.

**Messages**

```
invalid host address.
```

```
No VPN exists.
```

```
vpn is not exist
```

**Common Errors** N/A

**Platforms** N/A

### 6.3 sflow collector *collector-id* max-datagram-size

Use this command to configure the maximum length of the output sFlow datagram.

**sflow collector *collector-id* max-datagram-size *datagram-size***

Use this command to restore the default maximum length of the output sFlow datagram.

**no sflow collector *collector-id* max-datagram-size**

Use this command to restore the default maximum length of the output sFlow datagram.

**default sflow collector *collector-id* max-datagram-size**

**Parameter Description**

| Parameter                                        | Description                                                                      |
|--------------------------------------------------|----------------------------------------------------------------------------------|
| <i>collector-id</i>                              | sFlow Collector ID. The range is from 1 to 2.                                    |
| <b>max-datagram-size</b><br><i>datagram-size</i> | The maximum length of the output sFlow datagram. The range is from 200 to 9,000. |

**Defaults** The default maximum length of the output sFlow datagram is 1,400.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration** The following example configures 1,000 as the maximum length of the output sFlow datagram for sFlow

|                        |                                                                                               |
|------------------------|-----------------------------------------------------------------------------------------------|
| <b>Examples</b>        | Collector.<br><pre>Ruijie(config)# sflow collector 1 max-datagram-size 1000</pre>             |
| <b>Verification</b>    | Use the <b>show sflow</b> command to display the maximum length of the output sFlow datagram. |
| <b>Prompt Messages</b> | N/A                                                                                           |
| <b>Common Errors</b>   | N/A                                                                                           |
| <b>Platforms</b>       | N/A                                                                                           |

## 6.4 sflow counter collector

Use this command to enable the sFlow Agent to send counter samples to the sFlow Collector.

**sflow counter collector** *collector-id*

Use this command to disable the sFlow Agent to send counter samples to the sFlow Collector.

**no sflow counter collector**

Use this command to disable the sFlow Agent to send counter samples to the sFlow Collector.

**default sflow counter collector**

| Parameter Description | Parameter           | Description                                   |
|-----------------------|---------------------|-----------------------------------------------|
|                       | <i>collector-id</i> | sFlow Collector ID. The range is from 1 to 2. |

### Defaults

|                               |                                                                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Command Mode</b>           | Interface configuration mode                                                                                                                                                                                |
| <b>Default Level</b>          | 14                                                                                                                                                                                                          |
| <b>Usage Guide</b>            | This command can be used for physical ports, SVI ports and sub routed ports and aggregate ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector. |
| <b>Configuration Examples</b> | The following example enables interface TenGigabitEthernet 0/5 to send counter samples to sFlow Collector 2.<br><pre>Ruijie(config-if-TenGigabitEthernet 0/5)# sflow counter collector 2</pre>              |
| <b>Verification</b>           | Use the <b>show sflow</b> command to display the sFlow counter sampling configuration.                                                                                                                      |

## 6.5 sflow counter interval

Use this command to configure the sFlow counter sampling interval.

**sflow counter interval** *seconds*

Use this command to restore the default sFlow counter sampling interval.

**no sflow counter interval**

Use this command to restore the default sFlow counter sampling interval.

**default sflow counter interval**

| Parameter Description | Parameter      | Description                                                                                |
|-----------------------|----------------|--------------------------------------------------------------------------------------------|
|                       | <i>seconds</i> | sFlow counter sampling interval. The range is form 3 to 2,147,483,647. The unit is second. |

**Defaults** The default sFlow counter sampling interval is 30 seconds.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** This command is used to configure the global sFlow counter sampling interval, and sFlow Counter sampling of all interfaces uses this sampling interval.

**Configuration Examples** The following example configures the sFlow counter sampling interval to 60 seconds.

```
Ruijie(config)# sflow counter interval 60
```

**Verification** Use the **show sflow** command to display the sFlow counter sampling interval.

**Prompt Messages** N/A

**Common** N/A

**Errors****Platforms** N/A**6.6 sflow enable**

Use this command to enable flow sampling and counter sampling on the interface.

**sflow enable [ ingress | egress ]**

Use this command to disable flow sampling and counter sampling on the interface.

**no sflow enable**

Use this command to disable flow sampling and counter sampling on the interface.

**default sflow enable**

| Parameter Description | Parameter      | Description                                  |
|-----------------------|----------------|----------------------------------------------|
|                       | <b>ingress</b> | Enables sFlow sampling in ingress direction. |
|                       | <b>egress</b>  | Enables sFlow sampling in egress direction.  |

**Defaults** The sFlow sampling function on an interface is disabled by default.

**Command Mode** Interface configuration mode

**Default Level** 14

**Usage Guide** If the direction parameter is not specified, sampling on both directions are enabled. The SVI ports and sub routed ports support only the **ingress** parameter. The ACL should be configured and applied on the interface before the flow sampling based on ACL matching is enabled.

**Configuration Examples** The following example enables the sFlow sampling on interface TenGigabitEthernet 0/5.

```
Ruijie(config-if-TenGigabitEthernet 0/5)# sflow enable
```

**Verification** Use the **show sflow** command to display the status of the sFlow sampling function.

**Prompt Messages** N/A

**Common Errors** N/A

**Platforms** N/A

## 6.7 sflow flow collector

Use this command to enable the sFlow Agent to send flow samples to the sFlow Collector.

**sflow flow collector** *collector-id*

Use this command to disable the sFlow Agent to send flow samples to the sFlow Collector.

**no sflow flow collector**

Use this command to disable the sFlow Agent to send flow samples to the sFlow Collector.

**default sflow flow collector**

| Parameter Description | Parameter           | Description                                   |
|-----------------------|---------------------|-----------------------------------------------|
|                       | <i>collector-id</i> | sFlow Collector ID. The range is from 1 to 2. |

### Defaults

**Command Mode** Interface configuration mode

**Default Level** 14

**Usage Guide** This command can be used for physical ports, SVI ports, sub routed ports and aggregate ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.

**Configuration Examples** The following example enables interface TenGigabitEthernet 0/5 to send flow samples to sFlow Collector 2.

```
Ruijie(config-if-TenGigabitEthernet 0/5)# sflow flow collector 2
```

**Verification** Use the **show sflow** command to display the sFlow flow sampling configuration.

**Prompt Messages** N/A

**Common Errors** N/A

**Platforms** N/A

## 6.8 sflow flow max-header

Use this command to configure the maximum length of the packet header copied during flow sampling.

**sflow flow max-header** *length*

Use this command to restore the default maximum length of the packet header copied during flow sampling.

**no sflow flow max-header**

Use this command to restore the default maximum length of the packet header copied during flow sampling.

**default sflow flow max-header**

| <b>Parameter Description</b>  | Parameter                                                                                                                                                          | Description                                                                                      |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
|                               | <i>length</i>                                                                                                                                                      | Maximum length of the packet header to be copied. The range is from 18 to 256. The unit is byte. |
| <b>Defaults</b>               | The default length is 64 bytes.                                                                                                                                    |                                                                                                  |
| <b>Command Mode</b>           | Global configuration mode                                                                                                                                          |                                                                                                  |
| <b>Default Level</b>          | 14                                                                                                                                                                 |                                                                                                  |
| <b>Usage Guide</b>            | Configure the maximum number of bytes of the packet content copied from the header of the original packet. The copied content is recorded in the generated sample. |                                                                                                  |
| <b>Configuration Examples</b> | The following example sets the maximum length of the packet header copied during sFlow flow sampling to 128 bytes.                                                 |                                                                                                  |
|                               | <pre>Ruijie(config)# sflow flow max-header 128</pre>                                                                                                               |                                                                                                  |
| <b>Verification</b>           | Use the <b>show sflow</b> command to display the maximum length of the packet header copied during sFlow flow sampling.                                            |                                                                                                  |
| <b>Prompt Messages</b>        | N/A                                                                                                                                                                |                                                                                                  |

## 6.9 sflow sampling-rate

Use this command to configure the sampling rate of sFlow flow sampling.

**sflow sampling-rate** *rate*

Use this command to restore the default the sampling rate of sFlow flow sampling.

**no sflow sampling-rate**

Use this command to restore the default sampling rate of sFlow flow sampling.

**default sflow sampling-rate**

| Parameter Description | Parameter   | Description                                                                                                                                                 |
|-----------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <i>rate</i> | Sampling rate of sFlow sampling. One packet is sampled from every <i>n</i> packets ( <i>n</i> equals the value of rate). The range is from 4,096 to 65,535. |

**Defaults** The default sFlow flow sampling rate is 8,192.

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** This command is used to configure the global sampling rate of sFlow flow sampling, and sFlow flow sampling of all interfaces uses this sampling rate.

**Configuration** The following example sets the sFlow flow sampling rate to 4,096.

**Examples**

```
Ruijie(config)# sflow sampling-rate 4096
```

**Verification** Use the **show sflow** command to display the sFlow flow sampling rate.

**Prompt Messages** N/A

**Common Errors** N/A

**Platforms** N/A

## 6.10 sflow source

Use this command to configure the source address of the output packets.

**sflow source { address { *ip-address* | ipv6 *ipv6-address* } } | { interface { *interface-name* | ipv6 *interface-name* } }**

Use this command to remove the source address of the output packets.

**no sflow source { address | interface }**

Use this command to restore the default source address of the output packets.

**default sflow source { address | interface }**

| Parameter Description | Parameter                         | Description                                              |
|-----------------------|-----------------------------------|----------------------------------------------------------|
|                       | <b>address</b>                    | Configures the source IP address of sFlow output packets |
|                       | <i>ip-address</i>                 | sFlow Source IPv4 address                                |
|                       | <b>ipv6</b> <i>ipv6-address</i>   | sFlow Source IPv6 address                                |
|                       | <b>interface</b>                  | Configures the source interface of sFlow output packets  |
|                       | <i>interface-name</i>             | sFlow Source interface (configured with an IPv4 address) |
|                       | <b>ipv6</b> <i>interface-name</i> | sFlow Source interface (configured with an IPv6 address) |

**Defaults** The default sFlow Source address is the local device IP address which is used to ping the destination IP

**Command Mode** Global configuration mode

**Default Level** 14

**Usage Guide** This command is used to configure the source IP address of the output packets. If a source interface is specified, the primary address of the interface will be the source IP address of the outputs packets. If the source interface is not specified or the IP address of the source interface is unreachable, for example, the interface is shutdown, the default source address will be used.

**Configuration Examples** The following example configures the source address of the sFlow output packets as 192.168.2.1.

```
Ruijie(config)# sflow source address 192.168.2.1
```

**Verification** Use the **show sflow** command to display the status of the sFlow sampling function.

**Prompt Messages** N/A

**Common Errors** N/A

**Platforms** N/A

## 6.11 show sflow

Use this command to display the sFlow configuration.

**show sflow**

| Parameter Description | Parameter | Description |
|-----------------------|-----------|-------------|
|-----------------------|-----------|-------------|

|     |     |
|-----|-----|
| N/A | N/A |
|-----|-----|

**Command Mode** Privileged EXEC mode/global configuration mode/interface configuration mode

**Default Level** 14

**Usage Guide** N/A

**Configuration Examples** The following example displays the sFlow configuration.

```
Ruijie(config)#show sflow
sFlow datagram version 5
Global information:
Agent IP: 10.10.10.10
sflow counter interval:30
sflow flow max-header:64
